After the bark has been culled and cleaned in this manner, it is boiled in a clear ley till the matter is of such consistency, that, being gently touched with the finger, it draws off in the form of hairs, or like a collection of fibres. During the time of boiling it is constantly stirred with a strong reed, and the waste by evaporation is supplied from time to time with additional quantities of the clear ley. To make this ley, they put two pieces of wood across the mouth of a tub, and cover them with straw, upon which is laid a bed of ashes a little moistened; and when boiling water is poured on the ashes, the salts contained in them are carried down to the tub. This is what is called a *clear ley*. After the bark is in the condition which we have just stated, it is washed with great care; for on this washing depends in a great measure the quality of the paper. It is put into a kind of sieve through which the water can flow freely; and great care is taken to turn it with the hand till it be sufficiently diluted, and reduced to soft and tender fibres. For the finest paper a second washing is requisite, and a piece of cloth is used instead of a sieve.

When the bark is washed, it is laid upon a strong and smooth table, and beaten with a kind of baton of hard wood till it is reduced to a proper consistency. Indeed it becomes so soft that it resembles paper steeped in water. The bark prepared in this manner is put into a narrow tub, with a glutinous extract from rice and the root *oreni*, which is very viscous. These three substances are mixed together, and stirred with the reed till they form a liquor of uniform consistency. The composition is then poured into vats similar to those used for filling the forms or moulds in our paper-mills.

As soon as the sheets are made and detached from the form, they are laid in a heap upon a table covered with a double mat. A small chip of cane is placed between every sheet, and this jutting out serves to distinguish the sheets, and afterwards to raise them. Every one of the heaps is covered with a plate or thin board of the exact size of the paper. In proportion as the paper dries, or is able to bear it without danger of being compressed into one mass, they lay on additional weights. This pressure, being intended to carry off any unnecessary moisture, is continued during twenty-four hours, when the sheets are, by means of the little pieces of reed, suspended to long plants in the open air, till they are completely dried.

The extract from rice is made in an unvarnished earthen pot, which is at first agitated gently, and then more briskly; new water is next poured in, and the whole is filtered through a linen cloth. The finishing of the process is determined by the viscosity of the substance. The infusion of the root *oreni* is prepared in this manner:—The root, peeled and cut into small pieces, is infused in water for one night, during which time it communicates a viscosity sufficient for the purpose to which it is applied.

The Japanese paper is of such prodigious strength, that the materials of which it is composed might be manufactured into ropes. There is sold at Serige, the capital city of the province of that name, a kind of paper which is fit for bed-hangings and wearing apparel, and so much resembles stuffs of wool and silk that it is often taken for them. There are four trees used in Japan for the manufactory of paper:—1. The true paper-tree, called in the Japanese language *kaadsi*, and characterized by Kæmpfer as *papyrus fructu mori celsæ, sive morus sativa foliis urticæ mortuæ cortice papifero*; 2. The false paper-tree, called by the

Japanese *katsi* or *kadsire*, and by Kæmpfer *papyrus procumbens lactescens folio longo lanceata cortice chartaceo*; 3. The plant which the Japanese call *oreni*, and which is named by Kæmpfer *malva radice viscosa flore ephemero magno punico*; 4. The *futokadsura*, named by Kæmpfer *frutex viscosus procumbens folio telephii vulgaris emulo fructu racemoso.* The description of these trees, as given by Kæmpfer, may be of service in leading botanists to discover the European plants and shrubs adapted, like the Japanese, for the fabrication of paper.

Before concluding this part of the subject, it may be proper to given an idea of the attempts which have been made to increase the original materials of paper in Europe. A slight attention to the Chinese process in reducing the bamboo to a paste, by a careful and ingenious analysis, and to the method employed by the Japanese in separating the principal fibres of the bark of the mulberry, will show the absurdity not only of taking plants without any kind of choice, but of giving them no preparation, except that of pounding them with mallets. With a proper selection and right treatment, it appears probable that many of the European plants might be used with great advantage in fabricating several kinds of paper. It is evident that the materials used by the Chinese require less labour and preparation than the stuff of linen rags. The sheets of the Chinese paper are easily detached from the form; they are laid in heaps, without the interposition of pieces of woollen cloth; the superfluous water is immediately discharged; and they require not, as in Europe, the vigorous action of presses to unite the parts more closely together.

Paper made from asbestos.

Asbestos is a fibrous substance of little strength, and the threads of which are easily broken. This substance has the peculiar property of supporting the action of fire without receiving any damage; and hence pieces of cloth and garters made of it are incombustible. From the knowledge of this property, paper has been made of asbestos. The manner of fabricating this paper is described in the *Philosophical Transactions* (No. 166). A certain quantity of asbestos is pounded in a stone mortar till it be reduced to a substance like cotton. All the parts of earth or stone remaining in the asbestos are then taken off by means of a fine sieve, and it is formed into sheets of paper by an ordinary paper-mill. Mixing it with water reduces it to stuff; but as it is heavier than that made from linen rags, it requires to be continually stirred when it is taken up with the frames. The only excellence of this paper is, that the writing disappears when cast into the fire. But as it is of a slender consistency, and easily torn, it is rather an object of curiosity than of use.

Paper made from rags.

This paper is manufactured throughout all Europe, in the East Indies, and in America, from linen and cotton rags collected in the cities and in the country. Paper made of linen rags was utterly unknown to the ancients. The *libri lintei* mentioned by Livy (i. lib. iv.), Pliny (lib. xiii., c. xi.), and other Roman writers, are demonstrated by Guilandin, in his Commentary on Pliny, to have been written on pieces of linen cloth, or canvas prepared in the manner of painters. But it is not sufficient to be certain that paper made from linen is a modern invention; it is necessary to know by what nation, and at what period, it was discovered. Polydore Virgil (*De Inventoribus Rerum*, c. ii., c. viii.) confesses his ignorance of this circumstance. Scaliger, without any kind of proof, gives the credit of the invention to the Germans; and Maffei claims it for the Italians. Other writers ascribe this honour to some Greek refugees at Basil, to whom the manner of making paper from cotton in their own country had suggested the idea. Duhalde is persuaded that Europe derived this invention from the Chinese, who, in several provinces, make paper of rags nearly in the same manner as we now do. But this invention was practised by the Europeans before they had any communication with China, and before the taking of Constantinople, at which time the Greek refugees were supposed to have retired to Basil. The precise date of this discovery in Europe is not exactly known. Mabillon believes that it took place in the twelfth century, and cites a passage of Pierre de Clugny, born in the year 1100, to prove it. The books which we read every day, says De Clugny, in his treatise against the Jews, are written on sheeps' and calves' skins, or on oriental plants, or, finally, *ex rasuris veterum pannorum.* If these last words signify paper such as we use, there were books of it in the twelfth century. But this citation is the more to be suspected, as Montfaucon himself, after the minutest search in France and Italy, could find no book on this paper anterior to the death of St Louis, in the year 1270.

The epoch of this invention was not approximately determined till 1762, when M. Mierman proposed a reward to the person who could procure the most ancient manuscript written on this kind of paper. The collection of all the memoirs sent to him, along with the manuscripts, was published at the Hague in 1767; and it appeared that this paper had been used in Europe before the year 1300.

In 1782 the Abbate Andrez published a work, entitled *Dell' Origine, Progressi, e Stato attuale d'ogni Letteratura*, in which he speaks of the discovery of many kinds of paper, and particularly of that made of rags. The same person maintains, that paper made from silk was very anciently fabricated in China, and in the eastern parts of Asia; and that the art of making this paper was brought from China to Persia about the year 652, and to Mecca in 706. The Arabs substituted cotton, the commodity of their own country, instead of silk, or rather of bamboo. This cotton paper was carried into Africa and Spain by the Arabs. The Spaniards, from the quantity of linen to be found in the kingdom of Valencia, seem first to have adopted the idea of using linen rags; and hence the most ancient paper of this kind is that of Valencia and Catalonia. From Spain it passed into France, as may be gathered from a letter of Joinville to St Louis about the year 1260, and it is discovered to have been made in Germany in 1312. The first paper-mill in England was erected at Dartford by a German named Spielman in 1588, who was knighted by Queen Elizabeth. In consequence of paper made from cotton being imported from the Levant, paper made from linen was introduced much later into Italy than into France, Germany, and England.[1]

Art of paper-making in Europe.

This manufacture owes, in a great degree, the prodigious advancement which it has attained in Great Britain during the last thirty years, to the ingenious and successful application of machinery. Many of its formerly tedious and uncertain processes are thereby greatly simplified and abridged, a remarkable instance of which is the improvement of cylinder-drying. The drying process used formerly to be effected mainly by the agency of the atmosphere; but, since the paper-machine was perfected, the paper is now made to pass in the web, as it is formed, over the surface of a certain number of metal cylinders heated internally by steam, and is dried off in less than two minutes, whereas it was formerly, and especially during winter, kept for weeks or months in a damp state, or exposed to severe frost, to its certain and great damage.

The manufacture naturally divides itself into that which is carried on in *hand-mills*, where the formation of the sheet, as formerly, is still performed by manual labour;

[1] See the work of Abbate Andrez, printed at Parma, 1782, in 8vo; and Mierman's *Collection*, published at the Hague.

Paper.

and that which is carried on by *machine-mills*, where the paper is formed upon the machine wire-cloth in one continuous web. To give a distinct view of the subject, it will be necessary to describe all the important parts of the operation in their order, most of which are common to both modes of manufacture.

Materials.

The materials principally used in Great Britain are old linen and cotton rags, which are collected in great quantity at home. A large quantity of rags, chiefly linen, is annually imported from the different countries whence the exportation is not prohibited,—viz, Germany, Italy, Sicily, and Hungary. For many years past a very abundant supply of material, formerly considered as totally worthless, has been obtained from the cotton factories in Manchester and its neighbourhood. We allude to the cotton waste and sweepings of the cotton-mills, which, by being *devilled*, that is, cleaned by a machine used in the cotton manufacture called a devil or skreening machine, and afterwards boiled in alkaline solution, and bleached, are capable of being converted into very tolerable printing paper.

The selection of the rags, if it should not have been performed before they are brought to the paper-mill, is there performed by women sorting them into their various qualities, which facilitates the work of the rag-cutters, whose business it also is to sort the rags into their different kinds as they cut them. The rags are then assigned, in bags or bales of from two to five hundredweights each, to the women in the rag-house. These women stand at small tables of about 3 feet square, the upper surface being composed of iron wire cloth, the meshes of which are about one-fourth of an inch square, whilst underneath there is a drawer. A knife or short scythe is firmly fixed in the centre of the table, in nearly a vertical position, and the woman is placed so as to have the back of it standing next her, and with a large wooden box divided into several compartments upon the floor, on her right hand. She then opens and examines the seams and patches of the rags, and removes the dirt, as well as any other noxious substances, such as pins, needles, buttons, silk, and worsted pieces, &c., that may be attached, which would be hurtful to the machinery, as well as to the quality of the paper. She cuts the rags by drawing them to her across the edge of the scythe, into pieces not exceeding 4 inches square, which are sorted and thrown into the boxes above referred to, according to their different qualities. A great deal of the dirt, sand, &c., passes through the wire-cloth into the drawer of the table, which is opened and cleaned out at convenience.

The rags, after being thus cut and sorted, are again carefully examined by women called *overlookers* or *overhaulers*, who have the charge of seeing that the work is properly performed, and that none of the noxious substances above referred to are allowed to remain in the rags. Much of the beauty and cleanness of the paper, when finished, depend upon the attention bestowed on this department; for any dirty or noxious substances, when once comminuted by the trituration of the *stuff* into an endless number of small particles scattered over the surface of the paper, are of course wholly fixed and irremoveable.

Several machines have been invented for the purpose of cutting rags, and thereby abridging the labour and expense. By means of rollers they are carried round a large cylindrical drum, on which knives, placed diagonally, revolve with considerable velocity and power, and cut the rags into small diamond-shaped pieces. But such machines have hitherto been found of comparatively little service, as of course they cannot perform the work of selection, or the removal of the impurities from the material, which can only be done by careful and close examination at the time of cutting the rags, and with the advantage of using the sharp knife to cut or scrape off the injurious portion. These rag-cutting machines, moreover, have been apt to cut the rags into very unequal sizes, leaving one portion much too large, and another portion much too reduced, for the due trituration of them afterwards.

After the rags have been cut and carefully examined, they are inclosed in a cylinder called a duster, the whole periphery of which is composed of iron-wire cloth; it measures about $4\frac{1}{2}$ feet in diameter, and is about 5 feet in length; and a part of the circumference opens on hinges to admit the rags, from one to two hundredweights of which are generally inclosed at a time, and remain in motion for half an hour or an hour. On the axis in the interior of the cylinder there are a number of spokes, each about 1 foot long, fixed transversely, which pass through the rags when they are in rapid motion, and toss them about so as to make them part the more readily with the dust, sand, and dirt, which may still adhere to them. For the coarser and dirtier descriptions of rags this machine is used with good effect before they are cut, and renders the operation of cutting the rags less accompanied with dust, &c., and therefore less unpleasant and unwholesome to those engaged in it. A great recent improvement which we have to notice is that of the duster or willow, as it is termed, being now open at both ends. These willows are of a much larger size than formerly, and are placed on a slope. The rags, in order to be freed from dust and dirt, are placed upon a revolving travelling felt, from which they are dropt into one end of the willow referred to, and, after being carried partially round it for some time, are dropt out at the lower end of the willow upon another travelling felt, whence they are conveyed away for use, or for being stored up, upon another travelling felt.

The women engaged in the rag-house cut on an average about three quarters of a hundredweight of home rags (that is, rags collected in Scotland and England) in the day of ten working hours, and about one hundredweight and a half of foreign rags in the same time. This arises from the latter being of a much heavier and stronger substance, generally speaking, than the former. Their wages amount to from 10d. to 1s. per day on an average. The nature of their employment, though it subjects them to the inhalation of dust and fibrous matter floating through the air, does not seem at all to injure their health, nor to warrant the adoption of what medical men have sometimes volunteered to recommend, that of breathing through sponges placed over their nose and mouth, to prevent injury to their chests and lungs.

The next process is that of boiling the rags in an alkaline ley, which is rendered proportionally strong, according to the lowness of the quality of the rags and the quantity of the colouring matter to be discharged. In some mills large open-mouthed coppers, with fire under them, are used for this purpose; in others, where there is a full command of steam, the rags are boiled in large square iron boxes, capable of containing ten or twelve hundredweights at a time. Part of the lid is made to move on hinges, or with a rope and pulley and balance-weight, for the purpose of the rags being placed in and taken out of the vessel; and before the steam is allowed to pass into the chest, the lid is secured by being screwed tightly down, and the joints of it formed by oakum to prevent the blowing of the steam. The steam passes through an upright iron pipe of about an inch and a half in diameter, through the centre of the lid down to the bottom of the chest, whence it diverges through a number of pipes or radii towards the sides of the chest. There is a false bottom, also of iron, which is in moveable pieces, about 6 inches above the real bottom; it is perforated by a number of small holes, to allow the boiling ley to pass constantly through the mass. (A sketch of a chest of this description will be found under the article BLEACHING).

The boiling process, however, having been unequally and imperfectly performed, from the want of agitation through-

out the mass of material in the vessel, revolving boilers of a cylindrical shape have been introduced, made of strong wrought-iron. Patents for these have been taken out by Messrs Donkin and Fourdrinier, both of London, and by Mr Robertson, near Edinburgh, by which the rags are much more completely boiled, and with considerable economy in the amount of alkali used, and in the labour employed.

The quantity of alkaline matter varies from four to ten pounds of carbonate of soda to each hundredweight of rags, according to their quality, with about one-third part additional of quicklime, to render the ley caustic. The boiling is carried on upon an average for about eight hours, after which the rags are cooled as gradually as possible, since the process of cooling, if rapidly carried on, tends to fix some of the black colouring matter again in the rags. Some makers use only lime in the boiling process, whereas others use pot and pearl ashes to a considerable extent; but we believe that a ley composed of soda and a portion of quicklime is most commonly employed.

The rags, after being thoroughly cooled, to which a gentle flow of cold spring-water let into the boiler materially contributes, are laid aside in large wooden chests for use, or at once conveyed in boxes on wheels into the engine-house, there to be reduced to pulp. As this is one of the most important processes, and requires the whole power of the mill, we shall explain it, with reference to fig. 1. Figs. 1 and 2

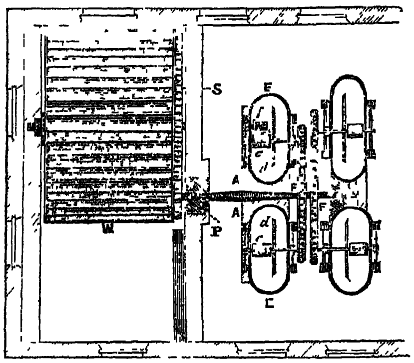

Fig. 1.

represent a plan and elevation of a paper-mill for four engines, E.E. W is the water-wheel, on which there are

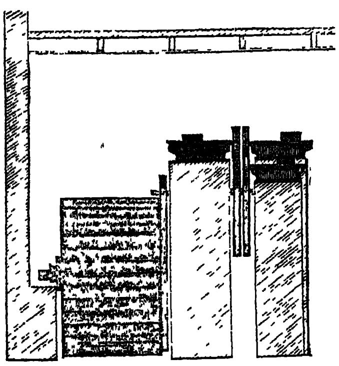

Fig. 2.

segments, S, of cast iron, which work into a main pinion P. This pinion is fixed on the same lying-shaft on which the spur or fly-wheels F are also hung. The motion is thus brought up to the proper speed, it being necessary that the pinions *p*, *p*, *p*, of the engines, and the engine-cylinders *c*, *c*, should perform about 150 revolutions per minute.

The engines, which are to be understood as large troughs of an elliptical form, with a division *d*, *d*, running nearly the length that intervenes between the foci of these imaginary ellipses, consist of two sorts, according to the purposes to which they are applied, viz., washing and beating engines,—the former being designed for washing and rubbing out the rags, and the latter for shortening or beating down the fibres, after the washing and bleaching processes have been performed.

These engines used to be made of strong wood, and lined inside with lead or copper; but for many years past they have been very successfully cast in iron, all in one piece, including the partition or mid-feather, as it is termed, although, from their awkward shape, it may be easily conceived to be rather a difficult matter to insure a good casting of such a mass. They measure about 10 feet in length, 4½ feet in width, and about 2½ feet in depth, being dimensions sufficient to contain about 112 or 120 lbs. of rags, but they are frequently capable of containing 2 cwts. From the rapid motion and weight of the machinery, and great friction necessary to triturate the stuff, it is evident that the solid fixing of the engines is a matter of extreme importance. It is usual, therefore, to build, from a solid foundation, a substantial mass of ashler-work (fig. 3, A A), of the size of each engine, for it to rest upon.

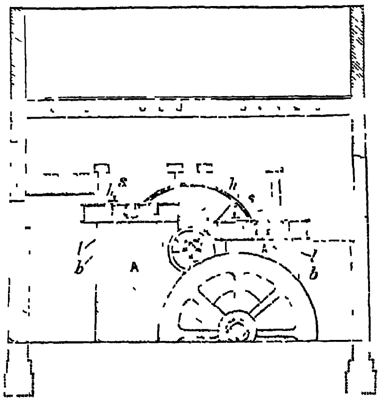

Fig. 3.

The cylinders in the engines, technically called the rolls, and by the revolution of which the rags are ground into pulp, are formed in general of solid wood. Elm is most generally used for this purpose. They are commonly about 2 feet in diameter, and 2 feet in length. Round the circumference are firmly fixed bars of steel parallel to the axis or spindle, in bunches of two together in the washing-engine, and three in the beating-engine, generally about eighteen or nineteen several bunches, and making therefore in all about thirty-eight bars in the washing-engine cylinder, and fifty-four or fifty-seven in that of the beating-engine. These steel bars are sunk and wedged into the periphery of the cylinder, and are, moreover, firmly fastened by means of hoops which are fitted into a groove in the ends of the cylinder, and, passing through the bars at a place cut out in them for that purpose, secure them firmly in their place.

Under the cylinder is what is called a plate (see fig. 3); that is, a number of steel bars, which lie fixed in a place provided in the trough *b* for them. They are accurately fitted, so as to form a segment of the same circle as the cylinder itself. The number of bars varies according to the kind of work performed at the mill; but in white-paper mills, in the washing-engines the plate has generally from twelve to eighteen bars, and in the beaters from twenty to twenty-four. The breadth of the plate is almost universally the same everywhere, namely, from 5½ to 6 inches. A plate 6 inches broad is found to require quite as much power, from the increased friction, as can in general be spared.

The thickness of the bars in the washing-engine plate is generally from about three-eighths to half an inch; and in the beating-engine from about three-sixteenths to one-fourth of an inch. In the latter they are made up with wooden or copper dividers, so as to afford the necessary thickness; in all, of five and a-half or six inches. The thickness of

the cylinder and plate-bars ought to be about the same proportion to each other; they are bevelled or tapered off about an inch or an inch and a-half from the edge, like a wedge; and those in the washing-engine being intended for opening and rubbing out the cloth and duly washing it, it is the opinion of the writer of this article that they ought not to be under the thickness of one-eighth of an inch, nor in the beaters under that of a shilling at the edge, after being ground—otherwise, by the too rapid conversion into pulp, the strength of the fibre would be materially injured.

The rags having now been boiled and brought into the engine-house, the engineer fills the engine or trough about half-full of water, till the bars of the cylinder, which project fully an inch from the wood, get hold of the water, and begin to turn it round. He then begins to put the rags into the engine, and spreads them with his hand. It will be seen from fig. 2 that the spindle *s*, which goes through the cylinder, is supported in its bearing upon an iron lever, called a lighter, *l*. A screw *h* is attached to it, and by moving that screw, the cylinder can be raised about three inches above, or depressed so as to come into contact with the bars of the plate.

Behind the cylinder it will be found that there is a rise (fig. 4, *r*) in the trough, which, on the side next the cylinder, forms a segment of a circle similar to that of the cylinder, and within an inch or two from it, and then descends by a rapid declivity to the natural bottom. This rise is called by the workmen *the backfall*, from the rags falling down upon it. The cylinder is always, when the mill is at work, inclosed in a wooden cover (fig. 5). The cover of the washing-engine used to have four slits or grooves cut down through the top of it, two on each side of the cylinder. The two slits *w* next the cylinder were made for a board of wood, which could be put in or removed at pleasure, being guided by grooves in the inside of the cover. The other two slits *c* contained two frames of very fine copper wire-cloth, having about 4900 holes in every square inch. These wire-cloth frames were generally fixed, being only taken out when any repairs were requisite.

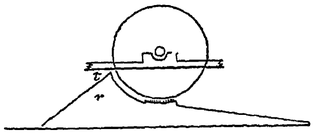

Fig 4.

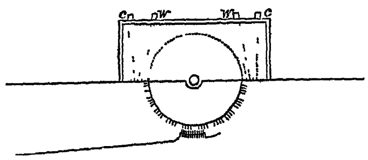

Fig. 5.

The washing process was formerly carried on by the rags or pulp being driven violently by the roller or cylinder in its rapid revolutions upon the wire-cloth frames referred to; but as this was found to be attended with a great waste of fibre, this plan has been very generally abandoned, and the dirty water now passes through the periphery of hollow cylinders covered with fine wire-cloth, which revolve *slowly* in the pulp, and which water is raised by inverted buckets inside of the cylinder, and conveyed away by a tube in the centre of the axis.

The rags being now filled into the engine, the cylinder, by means of elevating the screw (fig. 3, *h*) is raised as high as it will go, as there is thereby room for a greater quantity of water being carried round with the dirty rags. In the bottom of the trough (fig. 1) there is a false bottom *f*, which is punctured through by a number of small holes, and which communicates with a cock. This cock, when kept fully open for the first twenty or thirty minutes, has the effect, in consequence of the pressure of water and suction, of carrying off a great deal of dirty water, as well as sand and loose particles from the rags, which have escaped former cleaning operations.

When the engine has been once filled with rags and water, of which there must be a large supply constantly flowing, the cylinder, by its projecting bars, working like the paddles of a steam-boat, draws them in. It then throws them up to the top of the "backfall" formerly alluded to, and the rags or pulp descend the declivity. By this means a regular progressive motion of the stuff is produced, which comes again and again under the action of the cylinder bars and plate. The cylinder is gradually depressed as the washing goes on, till it comes as nearly as possible in contact with the plate when at its lowest point. The plates are not placed directly in line with the bars of the cylinder, but lie at an angle of about five degrees. This prevents the one from being locked against the other, should the cylinder, from any cause, be too much depressed; and it is moreover necessary that they should be in that position, to promote the reducing of the rags to pulp, on somewhat of the same principle with the cutting process, performed by a pair of scissors—the one blade forming an angle with the other.

To make good paper, a great deal depends upon the state of the engines, bars, and plates. If these be not in proper working order, well fitted together, and adapted for the description of material worked, it is impossible that any subsequent care can remedy the mischief done in the engine-house. It is much to be regretted that the great demand which has prevailed for paper for many years past has induced manufacturers generally to sacrifice quality to quantity, by hurrying the process, which impairs the strength of the fibre, and injures the texture of the paper.

If the bars and plates of the washing-engines are kept so sharp as to cut the rags, nothing can be conceived more injurious. Every paper-maker knows that the stuff is rendered mellow and soft by being rubbed out by blunt bars and plates. The longer the time occupied by this operation the more water will the stuff incorporated with it hold when it is worked into paper, and the less easily will the water drain off from it, which is always a sign of strong paper. Stuff, on the other hand, which has been quickly prepared by sharp tackle, never has the water properly beaten up with it; but the fibres, having been *cut* down, as it were, are held in suspension in the water merely, and the paper made from such stuff is always weak, flimsy, and perishable.

An abundant supply of fine water is very essential to produce paper of fine quality. When the rags are first begun to be washed, the engine consumes about a hogshead per minute for the first half-hour; but this quantity is soon diminished by the rags being opened up into pulp, and thereby taking up more room for themselves in the engine, till, towards the conclusion of the washing process, the water which passes through the washing-cylinders does not amount probably to one-twentieth part of that quantity.

In reducing the rags to half-stuff, about three or four hours have been hitherto considered as necessary for fine papers; but, from the desire to produce a large quantity, it is the practice of most machine-mills now to do this in half the time, to the great injury of the fabric. The power required to keep each of the cylinders moving the stuff, when pretty near to the plate, is equal to about seven horses.

The rags having undergone the process of being washed and *broken in*—that is, rubbed into half-prepared pulp, the engineer shuts off the supply of washing water, and then, by means of an iron hook two feet and a half long, which he inserts into the cavity of a conical brass valve, fitted into a pipe at the bottom of the trough or engine, raises that valve, and the half stuff then flows through a pipe of about six inches diameter, into the bleaching-house, situated in the under story, where it is received into a draining-chest of pretty large size, and suffered to part with the water, which flows through a number of very small holes

bored in the wood. As soon as the stuff is emptied, the washing-engine is again filled with rags as before.

The bleaching process is carried on in some mills by the rags being subjected in close chambers to the action of chlorine, which is produced in leaden retorts, from sulphuric acid, sea-salt, and the black oxide of manganese, and for an account of preparing which, we refer to the article BLEACHING. In a great many mills, however, where this mode was long carried on, it has been entirely abandoned, and the practice of steeping the rags in a solution of chloride of lime has been very generally substituted. The advantage, in the latter process, consists in the stuff not being so much injured in the fabric as if exposed to the chlorine itself; and although the whitening effect may not be produced so speedily or completely as if done by the action of the gas, yet, by giving the steeping process plenty of time, that is nearly compensated for, and there is much less waste in the latter than in the former process.

The bleaching-house for steeping consists of a long apartment, regulated in extent by the number of chests necessary for the carrying out of the works. A passage of three or four feet wide goes down the middle, and on each side are arranged stone chests, about three feet deep, and containing about fifty-seven cubic feet. In each there is a false bottom, which has been made of many different materials—viz., lead, copper, zinc, wood, stone, slate, &c., none of which is so effective as could be wished in resisting the action of the chlorine, and which therefore require frequent renovation. The false bottom is pierced through with a number of very small holes; and under the false bottom there is a small pipe, into which a valve is fitted, and attached by a wire reaching up to the top of each chest, by pulling which the liquid is allowed to escape at pleasure into a large tank extending under the whole of the chests. In this tank is sunk a pipe, with a pump, for the sake of raising the liquor. Although this solution be now very weak, yet it is much better for the purpose than pure water.

The half-stuff having come down from the washing-engine into the draining-chest, which is situated about three feet higher than the level of the stone bleaching chests, and being now freed by drainage of a great part of the water with which it descended from the engine, a part of one of the sides of the draining-chest, being a kind of door on hinges, is opened, and the stuff is promptly raked into an iron square box lined with wood or metal, which moves on a railroad fixed along the passage above referred to, and is carried to each of the chests in succession, as they are ready to receive the stuff. About one hundredweight of rags is laid in each chest, and receives upon an average from six to eight pounds of Tennant's strong saturated chloride of lime, according to the quality of the rags, in solution with about twelve gallons of water; and the chest is then nearly filled up with the weak liquor pumped from the tank. Great care is necessary to keep the stuff frequently stirred, otherwise the whitening throughout would not go on regularly. A great saving of time and labour is derived by the process of stirring being performed in what is called a "poaching-engine;" that is, a trough or engine with a cylinder in it, being provided to contain the rags after being *broken in*, into which the necessary quantity of the chloride of lime is introduced, and the contents thoroughly agitated by the action of the cylinder, as above described in the case of the washing-engine. It is always found that, from the effect of the air and light, the upper stratum of the stuff in the chests becomes white, whilst what is under is for some time but little affected.

The stuff is allowed to remain in the steep for twenty-four hours before the liquor is allowed to drain off, and of course there must be as many chests as there are hundredweights of stuff prepared in the twenty-four hours. But it is found not to have reached its maximum of whiteness even in twenty-four hours, for the stuff which has been set to steep on Saturday, is always found on the Monday mornings to be of a somewhat purer white than on any other day.

After the time for steeping has expired, the stuff is again lifted into the iron box formerly mentioned, which, being full of stuff, is moved on the railway till it is placed on a moving sole of a Bramah hydraulic press, which is situated in a convenient part of the passage; and the water being injected by pumps moved by the machinery of the mill into the piston of about ten inches diameter, causes by its great pressure the iron sole, with the wet bleached stuff upon it, to rise against a wooden "ram," as it is called, of the exact size of the box containing the stuff. What remains of the chloride in solution, as the ram enters into the box, is thus gradually pressed out, and flows into the tank formerly mentioned as situated under the chests. The ram enters into the box about one-half of its whole depth, and it will be seen by the annexed table what space is occupied by a hundredweight of the material in its raw and manufactured state at different stages of the process.

One hundredweight of linen rags, cut but not pressed, occupies a space of about......	$5\frac{1}{2}$ cubic feet.
When in the washing-engine in process of washing...	46 "
When drained of all the water that will flow from it	$25\frac{1}{2}$ "
When pressed by the ram	$7\frac{1}{2}$ "

The object of pressing out the liquid weak chloride of lime is to lighten the labour of raising the stuff to the higher story of the engine-house again, and also to render the process of washing it out the more easy; for it is most essential that none of the bleaching matter should be left in it.

This washing is performed in precisely the same way as that of the rags, and goes on for about an hour, after which, in the same engine, the pure water being shut off, the pulp is reduced considerably in length of fibre in the same engine with *blunt* tackle, which tends to soften the stuff, and make it mellow. The engine which is specially set apart to wash out the remains of the chlorine, and to soften the stuff, is sometimes called the intermediate engine; the stuff being now half way between rags and paper, and called *half-stuff*.

The stuff is then let down to the beating-engine by lifting a valve in the pipe, and it is then beaten down by tackle considerably sharper than that in the washing-engines. The stuff is here, as it were, combed out into fibres of perhaps one-twentieth of an inch in length, and this operation for fine paper ought to take from four to five hours; and, from the friction between the cylinder bars and those of the plate, the stuff ought to become moderately warm. It is now in a condition to be made into paper; and, by a valve being lifted, it flows out of the beating-engine by a pipe which conducts it to a large stone or wooden reservoir, called a chest, in the vat-house or machine-house.

Making paper by the hand.

The apparatus for the formation of the paper in single sheets at a time by the hand consists of—

1. A chest for receiving the prepared stuff, and which, if there be enough of fall in the situation, it is extremely desirable to have situated about three feet higher than the vat, in order that the stuff may flow from the chest to the vat gradually as it is worked into paper, otherwise it must be lifted by a lad at intervals by means of a copper pan.

2. The vat, which is a stone vessel about six feet square, and about four deep. It is agitated by a *hog* or little wheel about twelve inches in diameter, which revolves through the whole length of it, to keep the stuff constantly stirred; for the fibrous particles, being heavier than water, would otherwise sink.

3. The moulds or frames, of which a pair is required, so that when the vatman is dipping the one into the stuff, the coucher may be placing the sheet on a layer of felts, of which from four to eight quires, according to the size of the paper, form a *post*,—that is, the whole quantity which is brought under the press at one time. The vatman stands at one side of the vat, and the coucher at the far corner of the side, on the vatman's left hand, and facing him; and between them is a narrow ledge of wood, on which the mould is sent from the vatman to the coucher. The vatman always holds in his hand a frame of wood called a *deckle*, which is about an inch broad, and is made to fit exactly all round the edge of the mould, for the purpose of forming a clean and not a ragged edge to the sheet: it is this which is called the water-edge, and which is so easily distinguishable from any species of edge that can be otherwise produced, as to have been generally adopted in paper used for bank-notes. This description of paper is, in consequence, generally made on moulds of the size of the note, that it may possess the water edge, for the purpose of rendering forgery more difficult.

The moulds are made of brass wires or wire-cloth fixed upon a wooden frame, which is generally made of mahogany. A number of wooden ribs are fixed across the frame, placed at intervals of about one inch from each other, for the wires or wire-cloth to rest on. When *wires* only are used, these are *laid* longitudinally along the frame and across the wooden ribs, and interlaced with a wire somewhat thicker than the wires running lengthways, which is placed on the top of each rib. Paper made on such moulds is called *laid*, in contradistinction to what is made off the *woven* wire-cloth, and which is therefore called *wove* paper.

When the vatman dips the mould into the vat with the deckle upon it, he takes up a quantity of the pulp, which has been previously mixed with a great deal of water, and well agitated by the *hog:* he then throws off a great portion of the stuff and water over the edge of the mould farthest from him, and bringing the mould to a horizontal position, shakes it to and from him, which connects the fibres together so as to form one uniform fabric, and shakes out the water. To attain this method perfectly requires a long apprenticeship, simple as it may seem. As soon as the pulp is no longer in a liquid state on the mould, the workman raises the deckle with his fore-fingers and thumbs from off the mould, and with his remaining fingers shoves the mould along the ledge before referred to to the coucher, who is ready to receive it, and who places it in an inclined position upon a small wooden curved stay, on which it reposes for a few seconds, that the water may be further drained from the newly-formed sheet. The coucher is in the meantime pitching a felt or piece of blanketing upon a wooden plank of the proper size, and then takes the mould and presses the face of it upon the felt, which receives and takes off the sheet of paper from the mould, still in a very wet state. The mould being now freed of the sheet formed upon it, is pushed back along a wooden bridge, as it is called, which is joined to the ledge, and is placed at right angles to it. The bridge crosses the vat in front of the vatman, and the mould lies on it ready to be used by him, whilst the other mould is employed by the coucher. The process is continued till all the felts, being placed above each other with a sheet between each, are employed, which takes about half an hour. A heavy plank is then placed on the top of the *post*, as this quantity is called, and the whole is drawn in on a railroad, or rollers, under a press which is contiguous, and where the water is squeezed out, either by means of a screw, or by a Bramah hydraulic press. The paper, when it comes out of this press, is so coherent as to admit of being handled, and the sheets are accordingly laid together in a pack by themselves, the felts being placed on a wooden deal between the person who takes off the sheets from the felts, called the layman, and the coucher, who immediately, with the aid of the vatman, begins a new post. The water-mark is produced by wires in the shape of the letter or design being raised upon the surface of the mould.

After a number of packs have been made, they are put into another press, where they are made to *sweat* by pressure; that is, just to part with a small quantity of water, which comes from them in single drops. If the pressing be carried on too quickly or too long, the paper would be damaged by the sheets adhering to each other, and *peeling* or tearing when attempted afterwards to be separated.

The paper is then parted sheet by sheet, so as to be enabled to undergo another pressure before it goes to the loft to be dried. In fine writing paper, it is the practice to part the paper twice over, pressing between each parting. This is to make the sheets lose the marks of the felts, and to get the paper as dry as possible before it goes to the loft.

The lofts consist of a number of spaces filled with *tribbles*, that is, hair ropes fixed into spars of wood, the ends of which are made to slide up and down the upright posts of wood, one of which is fixed at the corner of each space. The paper is hung up in *spurs*, as they are called, of five or six sheets thick, upon the ropes, by the help of a wooden cross, shaped somewhat like the letter T. The workman holds this cross at the lower part of it, and the top of the cross must be as long as the width of the sheet. The dry-worker then, with his left fore-finger and thumb, pinches the corner of the hard-pressed *pack*, which has undergone one, two, or, if fine writing paper, three hard-pressings since it left the felts. He then partially raises by that corner the spur of five or six sheets, and with the cross gently catches the paper, which he slips over the hair-line, and leaves it there suspended. The pack is placed on a table which moves on small wheels, and against which the workman stands, and which he can push or draw with ease to any part of the loft that he pleases. When the tribble lines are all full, he pushes up the sides or spars upwards along the upright posts, which are bored all the way up for small pins of wood that support the tribbles. About eight or nine tribbles fill a *room*, as it is called,—that is, each space. The sides of the lofts are boarded with spars of wood placed vertically, about four inches wide and four separate. Inside of these are shutters made exactly similar, but fixed on wheels which move in a groove, so as to shut in the loft entirely or partially, or leave it open, according to the state of the weather. Many lofts have, in addition, woollen curtains within the shutters, which, with the addition of the heat derived from steam carried round the loft in pipes, are most serviceable for drying, when the state of the weather renders it impracticable to dry by the air. When the weather is favourable, the paper, before being sized, may be dried in twenty-four hours. After being sized, it ought not to be dried in less than three or four days, as by too rapid drying the size has a great tendency to fly from the paper; and therefore, when hung up after undergoing this process, the shutters are, in general, immediately closed upon it, so as to make the drying as gradual as possible.

The paper up to this point is quite bibulous, and therefore unfit to bear the ink. It is therefore transferred, when dry, to the sizing-house. The size is made from the refuse of tan-yards, called *scrolls*, consisting of the parings of skins, pates, ears, &c.; which materials range in price, according to quality, from about L.40 to L.70 per ton when thoroughly dried. The scrolls, as these pieces are called, are, after being made as clean as possible, immersed in water, which ought not to exceed in temperature

130 degrees, being sufficient to dissolve the gelatine, otherwise the gelatine is of a darker or browner colour. The gelatine is then gradually and carefully strained off through straw, branches of trees, charcoal, &c., and lastly, through fine flannel bags. An addition of alum, to the amount of about one-fourth of the weight of the scrolls, is then made. The size is run into chests or casks for use, where it soon congeals. When run off, it is much too strong to size any description of paper with. When the sizing operation is to proceed, therefore, it is mixed up and diluted with water, in a small boiler, and heated with steam. From the boiler it is made to flow in a spout into a tub of about five feet square, which is also heated with steam introduced under a false bottom, it being very essential to use it always very hot. An additional quantity of alum is also made use of, which is placed in the spout, and is gradually dissolved as the size flows down in contact with it. The workman stands close to the tub, and dips the paper in handfuls, containing about six quires on an average, with a wrapper at top and bottom, which he soaks thoroughly, turning it backwards and forwards, so that every portion becomes completely penetrated with the size. It is also allowed to remain some minutes soaking in the tub, being held by wooden pincers suspended by a balance-weight. He then carefully lifts them out one by one, and places them in a press, adding to the heap till the press is full. The surplus size flows, and is then, by a moderate pressure, squeezed out of the paper, the edges of which are next rinsed by hot water, before the pressure is taken off, to prevent them from adhering together; and with the same view the heaps of paper, when taken out of the press, are enveloped with woollen cloths, so as to exclude the cold air. Moreover, to prevent the paper from sticking when it is strongly sized, it is separated or parted sheet by sheet, after which it is pressed moderately, so as to make the *spurs* slightly adhere together. It is better to keep the sized paper forty-eight hours before hanging it up to dry, and then the more gradual the drying the better. Another mode of sizing, which tends to save both labour and wrappers, is by means of a machine or wooden table about two feet from the floor, above which are placed two spars of wood parallel to each other, supported from the table. The spurs of paper are placed vertically on the table, that is, their long edge resting on the table and across it; and between each spur a thin slip of wood is introduced, which is attached to the spars of wood by means of hooks and eyes. The slips of wood are then pressed somewhat tightly together, so that the whole mass is easily raised, by a pulley fixed overhead, to a small carriage, by which the paper, when raised from the table, and thus suspended in the air, can be wheeled right over the tub, into which it is let down to receive the size. This tub is divided into two compartments by a wooden sole affixed to a screw, which lies horizontally, and is worked by some wheels, so as to press the paper. The paper, when let down into the other portion of the tub, has the frame and slips hooked away from it as soon as it is gently pressed by the screw, so as to keep it from falling down. The hot size is then allowed to flow in amongst the paper, on which, when thoroughly soaked with size, the screw is made to work, and to press it. A board which has been pressed down against the paper is now fastened to a board of similar construction by means of strong iron clamps, and the screw is worked back again, leaving the paper still under pressure. A strong false bottom of wood, on which the paper rests, is now raised by means of a rack and pinion, and with it the paper and the heavy planks confining it, above the liquid size; and whenever the pressure is removed, it is at once set aside as sized. The size left in the tub is then pumped back to the boiler to be again heated.

There cannot be a stronger evidence of the necessity for the stuff being well prepared, in order to obtain a sound paper, than the process of sizing. If the stuff has been slowly prepared by trituration, so as to hold a good deal of water, it will also hold and keep the size in a manner corresponding thereto; whereas a quickly prepared stuff, which has been cut rather than rubbed out, however strong the size that may be employed, can scarcely be got to keep it. It is also very injurious should any of the chlorine or chloride of lime be left in the paper unwashed out, as the glutinous matter is thereby decomposed, and rendered of no avail.

After the paper has again been thoroughly dried, it is taken to the *salle* or finishing-house, where it is pressed very often, in order to take out the marks of the lines, and to improve the surface generally.[1] The hot-pressing is carried on by means of smooth paper boards which have been glazed by passing through metal rollers. The paper is placed alternately between these, and heat is communicated by hot iron plates being laid upon these at intervals of about six quires. These plates are heated in an iron box, into which a supply of steam is sent, and where they do not generally require to be more than five or ten minutes. These plates, by means of pressure, communicate a good deal of heat throughout the paper, after it has been all brought under the action of the hydraulic press.

In consequence, however, of the general use of steel pens, and perhaps to some extent of the fashion of the day, it is necessary to finish fine letter-papers now with a much higher gloss, and various methods have been adopted for this purpose. One of these methods consists in using, instead of the hot-pressing smooth glazed boards, copper plates made very smooth, on which the sheets of paper are laid, a copper plate and a sheet of paper alternately. These, when filled with about one quire of paper, are passed between a pair of iron rollers, where the pressure is equal to twenty or thirty tons, and which are driven by the machinery of the mill. By moving a clutch, a small wheel is thrown in and out of gear at pleasure, so that the workman can instantaneously reverse the motion of these rollers, and they can be made either to take the copper plates away, or to return them again towards him after they have passed through, so as to sustain the pressure twice over. Another workman attends on the other side of the rollers to return the copper plates. It requires three women to be attending to fill and empty each set of copper plates, one filling in the rough, another taking out the smooth paper, and the third lifting off the copper plates in succession, and placing them on the sheets of paper as these are laid down. When the paper has had three or four pressures, it is pretty smooth, and is then denominated *rolled* or *hot-pressed*; but if it be passed more frequently through the rollers, it acquires a higher surface, and is then called *glazed*. Each set of three women can in this manner fill in about twenty reams of paper in one day. The work is laborious, from the quickness with which it is done; and, from the sharp edges and corners of the copper plates, and of the paper itself, the women are very liable to have their fingers cut, so that this department of work is not very popular, and in some manufactories it has acquired the name of the *tread-mill*.

Another mode of giving a higher surface to paper is

---

[1] A very laborious operation, and one injurious to the paper, used to be performed in the salle—that of picking out the knots and lumps in the paper by means of small knives. The paper could not fail to be injured by this system of scraping, and the ink was always apt to sink where it had been scraped; but this operation is now rendered almost unnecessary by the invention of the strainer, through which the pulp is strained before it passes into the vat.

Paper.

by passing it through a calender, or cylinders which have been made of cast-iron, copper, or brass, or one of them, like the ordinary calenders, consisting of a paper bowl. But these, although they be accurately fitted and polished, are all more or less liable to receive marks or indentations from any minute hard substances, or from folds or creases which may be in the paper, and which they give out again, and thus mark the paper.

The paper is now, after being rolled or glazed, told out into quires or half quires, folded, and made up into reams, and is subjected to pressure under hydraulic presses in every stage. It is then tied up in a wrapper, with a label on it, for the protection of the duty, and the label being filled up by the trader and officer respectively, the paper is weighed by the latter, and stamped, so as to denote the amount being charged against the maker.

Machine paper-making.

Hitherto we have considered this manufacture as carried on by the hand. But the hand-mills in different parts of the kingdom are nearly extinct. Excepting for some kinds of drawing-papers, papers for account-books, and some others, all paper is now made by the machine, and we do not believe that the quantity or weight of hand-made paper amounts to one per cent. on the whole quantity manufactured.

Fourdrinier's machine.

The machine which is now used so universally all over the kingdom is the invention of Louis Robert, and was brought to this country by M. Didot of Paris, who came over to England, and, with the assistance of the MM. Fourdrinier, and Donkin the engineer, succeeded in perfecting the invention, and in acquiring a patent right, which was afterwards renewed for a longer period by Parliament, in consequence of the patentee's not having derived sufficient compensation.

The stuff flows out of the chest C (Plate II.) by a pipe furnished with a cock, which is opened more or less wide, according to the thickness of the paper to be made. It falls into the spout, where it meets a large supply of water, which has been in great part passed through the web of pulp before, as will be afterwards explained. It then falls into the vat at the opening of the spout, and is there agitated by the little hog, as it is called.

The strainer S is generally used before the stuff flows into the vat. It consists of a brass rectangular trough 6 feet long, 2 feet wide, 4 inches deep, the bottom being a plate of brass cut into very fine slits or grooves, to suit the length of fibre of the pulp usually put through it. The strainer is driven by means of a light iron or brass shaft which passes above it, and has two small notched wheels, one placed above each end, and working into the frame of the strainer. When the shaft revolves, therefore, it will be seen that at every notch the strainer is raised, and then quickly descends by its own weight, so as to produce a continual jerking motion, making about a hundred and thirty strokes per minute. The stuff is now flowing in, and the bars are placed so close to each other that the fibres must necessarily pass longitudinally, and any knot or extraneous substance larger in diameter than the width of the slit is kept out of the pulp.

After the stuff has been strained and mixed in the vat by the agitator working in it, it is allowed to flow out by a number of holes in the side of the vat on an endless fine wire-cloth, *w*, on which the web is formed. This wire-cloth, which must be perfectly level, moves upon a number of small copper rollers, about an inch and a half diameter, and an inch and a half separate. These rollers rest upon a frame, which is left so far free as to be moved laterally by a rod which is attached to a crank, and thus is produced a vibration, more or less quick, according to the nature of the stuff, which causes the water to flow through the wire-cloth, and connects the fibres of the pulp together. A large shallow wooden vessel is placed below the wire-cloth, called the save-all, which receives the water and the flour of the pulp in large quantity. The water then passes through a spout on the side of the machine, and flows into a box, from whence it is thrown back by stuff pumps into chests CC.

Paper.

The edges of the paper are formed by pliable deckles, which were formerly made of leather, then of woollen cloth. Belts or deckles, however, composed of alternate layers of linen and caoutchouc, firmly cemented together, are now most generally employed. These belts are half an inch thick, and about sixteen feet long, and are drawn by the pulley upon the shaft *g*. It will be seen that they move under a solid plate of iron or brass, which is moderately pressed down upon them, but not so much so as to impede their free motion along with the wire-cloth, whilst they fit sufficiently tight to it to prevent any of the stuff from flowing away laterally before the paper is set.

By the time these caoutchouc deckles leave the wire-cloth, the stuff is no longer fluid, though a good deal of water still flows from it. The wire-cloth then passes on with the pulp upon it through the cylinders *tc*, *uc*, of which the under one is of metal, covered with a jacket, as it is called, of felting or flannel; and the upper one is generally of wood, but hollow, and covered with mahogany about an inch and a half thick; that wood being less apt to shrink or get out of shape than any other; and this roller also has a jacket. A slight pressure is given by these, which are called the wet-press cylinders; and after this stage, the paper pulp is led upon an endless felt, which must proceed exactly at the same speed as the wire-cloth, as, by any irregularity in their motion, the pulp would break. The wire-cloth returns back round the under wet-press cylinders, to receive a new supply of pulp, and is supported by a series of copper tube rollers, which revolve by the friction of it. The wire-cloth is generally about twenty-five feet in length by five feet in width, and has about sixty holes in the lineal, or 3600 in the square, inch.

The web of paper, still in a very wet state, is now carried away by an endless felt, between cast-iron cylinders *k*, *k*, where it sustains a severe pressure, and where a great deal of water is squeezed out, after which the paper may be handled. It then passes through a second pair of press cylinders, that the mark of the felt which was impressed on the under surface by the first pressure may be removed; and for this purpose the under surface is now placed next the metal cylinder. The web then passes over the surface of a number of cylinders, heated with steam, and arranged as to number and relative position according to the ideas of the manufacturer or millwright. When the web has passed over about 70 lineal feet of surface heated in this manner, it is dry, and is wound upon a reel, or wooden roller of small diameter, in order to be either sized in the sizing-machine, or, if already sized in the pulp, to be passed through the cutting-machine hereinafter described, as the case may be.

The paper-machine moves at the rate of from twenty-five to sixty or seventy feet per minute. The whole process, therefore, in its transition from liquid pulp at the one end to dry paper at the other, occupies scarcely two minutes. This, in the ordinary state of the weather, could not formerly be done in less than seven or eight days. Supposing, therefore, that the machine makes ten yards lineal of a web per minute, or 600 in the hour, this is equal to a mile in three hours, or four miles per diem of twelve hours. The paper is generally made about fifty-four inches wide. Reckoning that there are 300 machines in Great Britain, and that they work twelve hours each day on an average (many go both day and night), the length of web would altogether be equal to 1200 miles, and the area of what was made would be about 3,000,000 yards daily.

Printing paper, which is now entirely made by the machine, is in general sized in the pulp. White soap, starch, glue, and dissolved rosin, are principally used for this purpose, with the addition of a few pounds of alum. Such of

these as are used are put through a sieve into the beating-engine. The web, before being dried off, is also in some mills passed through hot size, the surplus of which is pressed out between two cylinders. This tends to strengthen the paper materially; but it is not easy for paper to keep the size if it be dried off hastily on the cylinders; and this is difficult, if not impossible, in the finer descriptions of paper, where the material is not so strong as that for more common kinds, and not so favourable for being thoroughly sized.

The fine bluish tinge which so many writing papers possess used to be derived from a mineral but very expensive blue, namely, the oxide of cobalt, generally called smalts. This article used entirely to be imported from Saxony, Denmark, and Sweden; but it is now almost entirely displaced by the artificial ultramarine, which has been chiefly derived from Nuremberg, Lyons, and more recently from the Prussian Rhenish provinces. The latter blue is much cheaper, and of an equally brilliant azure as that of the smalts; the only disadvantage being, that if the sized paper remain long in the damp state, the beautiful deep blue is apt to pass into a greenish shade by the action of the sulphuric acid in the alum upon the ultramarine.

The finest writing-papers, which are now almost wholly manufactured upon the machine, are sized by being passed in the web through a solution of gelatine and alum, at a temperature of about 100°, and are thereafter, in some mills, and without loss of time, dried off by being carried round a succession of drums or circular frames, on iron rods or wooden spars; there being inside of each drum a fan driven at great speed, and projecting the air (about 80° Fahr.) upon the surface of the paper. This mode of sizing constitutes one of the great improvements introduced within the last twenty years, and was chiefly the invention of the late Mr Ranson of Ipswich. By the agency of the atmosphere, it formerly required, in favourable circumstances, two or three days for the drying of gelatine-sized paper, when hung upon the hair-lines in the drying-lofts. At present the web of sized paper travels over the surface of the drums, which are usually arranged in pairs. These are generally of the diameter of about 3 feet; and there being for each machine about thirty of them, the paper travels about 300 feet in about ten minutes, when it comes out at the end perfectly dry, and is then passed through the cutting-machine, where it is cut into sheets of the size intended. In many mills in England and Scotland, the operations of forming the web on the wire cloth, drying on the heated cylinders, again wetting it by passing it through the size, pressing out the surplus thereof, drying it by currents of air as above described, and then cutting it into sheets, are performed continuously and in the same apartment.

Excepting in great Britain and Ireland, almost all writing-paper is sized or made capable of bearing ink by means of a vegetable size, consisting generally of a resinous soap, and introduced into the pulp of the beating-engine when nearly ready for being made into paper. In Great Britain and Ireland, as already described, an animal size from gelatine is employed for such papers. The former takes a more glossy surface, and is of a more silky feel, whereas the gelatine-sized paper has more firmness and what is called in the trade more "mettle," which is more in consonance with our natural taste than the softer and more highly polished surface of the foreign papers referred to.

The process of water-marking machine-made paper in the web was, fifteen or twenty years since, considered an impossibility; but is now very effectually and ingeniously accomplished. A very light wire cylinder, of about 6 inches diameter, is placed in framings so as to rest across and upon the wire-cloth of the machine, and to be moved by it. The cylinder is covered with wove wire-cloth, or formed of "laid wires," containing letters or devices similar to those stitched on the wove or laid moulds used in making paper by hand. The cylinder being driven by the friction of the advancing wire-cloth, impresses on the pulp, at the place where it has scarcely ceased to be fluid, the devices and letters upon the surface; and as, by means of the vacuum-box, over which the wire-cloth passes immediately thereafter, the water is rapidly drawn from the pulp, the water-mark remains clear and distinct by the pulp being deprived at once of all fluidity, which would cause the pulp partially to run together again, and thus a faint or imperfect water-mark would be produced.

Cutting-machines.

Several machines have been invented for cutting paper as it is made by the machine. Amongst others, one by MM. Fourdrinier of Staffordshire has been very generally introduced and approved of. As it is capable, however, of cutting five or six thicknesses of paper at once, it is not in general attached to the machine, but is found in some contiguous convenient place. The paper is reeled, as described above, on small rolls of about 6 inches diameter, and these are placed with the spindles lying in grooves in a curved frame, whence they are taken and passed round a drum, and then through some small rollers. After the web is divided longitudinally by circular knives, which are set opposite each other upon shafts on each side of the paper, the progress of it is stopped for an instant by a very ingenious contrivance, when a knife descends, beginning at one side of the web, which is held fast by a heavy weight laid across it, and cuts it across. The web then goes on till it has passed as much paper through as is the requisite size of the sheet, when the knife again descends. The sheets thus cut are carried on by a small felt moved in connection with the rest of the machinery.

The paper-machine is peculiarly suited for making thin papers, which are not easily made by hand without great damage in the couching department, from the difficulty of getting off the sheet whole upon the felt; namely, the thin paper for copying letters, tissue-papers used for putting before prints, &c. A large quantity of remarkably thin paper, also, made from old ropes of a better description than usual, and called pottery tissue, is made for printing the colours on china, &c., which could never have been made by hand. The machine has also been of immense service in producing paper of large sizes of sheets for newspapers, which could not have been worked by hand. It would have been very serious and laborious work for a man to make paper even large enough for a single sheet of the *Times* newspaper, which measures 2 feet by 3. Indeed, till about 1825, the legislature restricted the size of newspapers to 22 by 32 inches, beyond which they could not be stamped; which restriction was done away with just as soon as it became possible to make by machinery any size of paper that might be desired. But perhaps in no department of paper-making has the advantage of the machine shone so conspicuously as in the paper used for paper-staining, and the consequent great reduction in price of the hangings. Before the application of the machine, the paper used by paper-stainers was of the size of 28 by 23 inches, called elephant. It required, in order to form a piece of 12 lineal yards, that sixteen or eighteen of these sheets should be pasted together, which is now rendered wholly unnecessary by the paper being furnished to the stainers in sheets of 12 yards each in length.

The chief seats of paper manufacture in Great Britain are:—

1. Kent, where it was first established, and where there are a great number of hand-mills for making fine water-marked writing papers. There are also a good many machines for fine writing and printing paper.

2. In Hertfordshire, Buckinghamshire, and Oxfordshire, the manufacture of fine printing papers is very extensively carried on, and all made by machinery.

3. In Lancashire and the continguous counties, it is car-

Paper.

ried on to a very large extent, the material, as already noticed, being chiefly derived from the refuse of the cotton mills, to which is added a mixture of cotton-bagging, of which there is a large supply, and which tends to strengthen the paper. This description of paper, however, both from the impurities which are inseparable from so very dirty a material as the sweepings of the cotton-mills, and from its soft spongy texture, is very inferior to that which is made out of a sound strong rag.

4. In Scotland the manufacture is carried on to a large and rapidly increasing extent. From the ready communication with London, and other causes, both fine writing papers and others find a ready market there. Independently of the white paper, there is manufactured in all parts of the country a large quantity of brown paper, made from old ropes, sacking, flax waste, &c.

Paper is considerably adulterated with plaster of Paris, sometimes to the amount of 30 per cent., for the purpose of gaining weight. This can easily be detected by burning a portion of a sheet, when the plaster will remain after combustion in an ashy whitish-coloured residuum. Brown paper is also often mixed up with a good deal of ochre or clay, the makers saying that it is for the purpose of giving it a nice brown colour, though it may be doubted whether it be not also with the intention of increasing the weight.

The following table, showing the strength of different kinds of paper, has been prepared from actual experiment. It denotes the number of pounds avoirdupois required to break a strip of paper 2 inches wide, both ends being secured above, and the weights attached to a small wooden roller, resting upon the strip of paper:—

	Wt. in grs. avoir of a superficial foot.	Wt in lbs., supported by a strip 2 in. broad.
Bank post, very thin writing paper, sized.	65	23
Ditto unsized, but thinner....................	48	13
Thick writing paper, machine made......	139	42
" " made by hand......	143	60
" drawing paper, machine made......	217	55
Newspaper, sized at the machine	113	39
Paper used for Scotch bank-notes...... ...	95	70
Strong cartridge-paper........................	135	64
Pink blotting-paper.......................... ..	90	10

The manufacture of paper has immensely increased in Great Britain and Ireland within the last twenty-five years, consequent upon the penny postage, the repeal of the newspaper stamp and of the restriction of the dimensions of newspapers formerly prescribed by law, and also from the greatly increased amount of our manufactures and exports. This will appear from a comparison of the account of the duty charged twenty-five years ago, and what it has amounted to since.

Up to 1836, all paper, excepting brown paper, made from old ropes, paid a duty of 3d. per lb.; but in that year the duty was assimilated and made 1½d. per lb. for all kinds, including the duty upon millboards and pasteboards, which were till that period respectively charged 3d. and 1¾d. per lb. The amount of paper, and the rate of duty in 1833 were as follows:—

First-class paper.........Lbs.	49,404,408	at 3d. per lb. duty.	
Second...................... "	15,531,059	at 1½d.	"
Millboard.................. "	28,325	at 3d.	"
Pasteboards.............. "	15,148	at 1¾d.	"
Total...............	64,978,940 lbs.		

and the amount of duty gross was L.763,104.

If this weight of paper had been charged at the same rate of duty which was imposed in 1836, and has continued ever since, the duty would have amounted to L.406,118 7 6

Add 5 per cent., imposed on all excisable articles in 1841, and ever since........ 20,305 18 4

L.426,424 5 10

Now, the actual duty charged, by the last report of the Commissioners of Inland Revenue for 1858, was,—Year ended 31st March 1857, lb. charged, 192,297,399; gross duty, L.1,244,143: 31st March 1858, lb. charged, 187,414,667; gross duty, L.1,244,723; showing the marvellous fact, that the quantity produced is as nearly as possible three times as great in 1858 as it was twenty-five years previously.

The supposed scarcity of the raw material, in consequence of the greatly increased consumption, has given rise to a vast amount of enterprise not always put forth with much wisdom, whereby all kinds of vegetable material have been collected throughout the world, and operated upon with the view of their being used in place of rags. Such materials being often procurable at a very low price, and in unlimited abundance, have been conceived to offer great advantage to the manufacturer; but it has been too frequently overlooked, that the cost of boiling and bleaching such materials is very great, and the waste attending their use is enormous, to say nothing of their unsuitableness in many cases for the purpose. Straw, which is used in several mills in England, and from which a pretty good paper for newspapers is made, costs only about L.2 to L.3 per ton; but we believe the cost of bleaching it will make the amount L.16 or L.18 in all; and when to this is added the fact, that we have reason to believe that not one-half, or even one-third, of the weight of the straw employed is got back in paper, and that the paper is necessarily much more brittle than that from rags, there appears to be no great advantage derived from its use. We allow, however, that as the reduction of straw, or such like materials, into pulp is much more a chemical than a mechanical operation, a great amount of mechanical agency is saved in the triturating process. We have seen many fibrous productions introduced as specimens from tropical countries, and particularly from the East and West Indies, several of which have been manufactured into paper of fine quality. The supply of such materials is stated to be unlimited; and no doubt, as soon as a demand for a new raw material exists, it will, through the enterprise and skill of Englishmen, be speedily forthcoming to any extent that may be desired.

The following statistics of paper-making will show the progress of that manufacture in the chief paper-producing countries besides Great Britain; viz., the United States, France, Belgium, and Germany. Paper-mills existed in Massachusetts and Pennsylvania as early as 1730; but it was not till 1830, when paper-machines began to be constructed in Connecticut and Massachusetts, that a marked advancement took place. The progress up to 1850 was such that in that year the quantity of paper imported did not exceed 2 or 3 per cent. of the amount consumed; and this small per-centage consisted chiefly of fine writing and fancy papers from England and France. Owing to the extensive demand for newspapers and cheap literature, more paper is said to be now consumed in the United States, in proportion to the population, than in any other country, or equal to the consumpt of France and England together. The quality of American paper is generally inferior; but of late years the finer sorts have been also produced by the aid of calenders. In 1850 the mills producing over $500 worth annually (L.104) were confined to the New England States, and those of New York and Delaware. The number of mills has since increased in the southern and western states; and in 1853 there were 750 mills, with 3000 engines, producing 120,500 tons of paper, valued at L.5,400,000. Of the 180,800 tons of rags required, 10,163 tons were imported (worth L.204,758), about one-fifth of which was from Italy; but the supply from that country is annually decreasing.

A paper-machine was first erected in France in 1815.

In 1850 there were about 200 machines, estimated to produce annually about 39,000 tons of paper, besides 250 vats producing over 2000 tons; in all, 41,000 tons. The following table shows the amount and descriptions of papers exported from France in 1849, as well as the amount imported:—

	Exported.	Imported.
White or ruled paper for music,............	6,283,145 lb.	10,802 lb.
Coloured, in reams or quires, for binding,	149,875 „	2,827 „
Envelopes, coloured............................	1,795,142 „	4,065 „
Paper-hangings.	1,421,315 „	276 „
Silk, India, and Chinese papers, &c,.......	2,029 „	13,416 „

The quantity of rags imported into France in the same year was nearly 800 tons; exported, less than 1 ton. Besides what is imported in the shape of rags, the cotton received from America, amounting annually to 55,800 tons, falls ultimately into the hands of the paper manufacturer, as its exportation is prohibited by statute.

Paper-making was not successfully carried out in Belgium till the close of the seventeenth century, and but little advancement was made till about the year 1820. Since that period, however, the number of mills has greatly increased. In 1849 there were 80 mills, with 2168 hands employed; the paper exported was valued at L.36,040, and the amount imported at L.2774. Of rags and other materials for paper-making only 14½ tons were imported.

In various parts of Germany during the last few years rapid progress has been made in the production of paper; and in the Zollverein States the exports in 1850 exceeded the imports. The number of mills in 1850 was 794, having 116 paper-machines, which produced about 37,000 tons annually. It is an important fact, that while at Berlin, and several other cities of Germany, very fine qualities of paper are produced and partly exported, the papers imported are almost exclusively of common quality. The kingdom of Prussia exported, in 1850, 14 tons of paper, and imported 1 ton. The first paper-machine was established at Berlin in 1818. In Austria there were in 1845, 40 machines and 940 vats, producing 15,000 tons of paper, and in 1850, 49 machines and 900 vats, producing 32,500 tons. In 1854 the number of mills was 350, chiefly in Lower Austria, Lombardy, and Bohemia. In Russia the manufacture is virtually in the hands of the government, who have had for many years several machines constructed in England, combining all the then existing improvements. The importation of paper is prohibited by means of enormous duties. (C. C.)

PAPER-MONEY. See Money.

PAPHLAGONIA was a country of Asia Minor, separated from Pontus on the E. by the River Halys (*Kizil Ermak*), and from Bithynia on the W. by the River Parthenius (*Bartan-Su*), and bounded on the N. by the Euxine, and on the S. by Galatia. The physical character of the district was not very favourable. The Olgassys, and another parallel mountain-chain, ran from E. to W., sending off many branches; the soil, especially in the south, was cumbered by large primæval forests, and the rivers were small, and had short courses. The country, however, was celebrated in the earliest times for the fine breed of horses that were reared in its pastures, and in later times for the beasts of chase that roamed through its wilds. All that is known of the history of the Paphlagonians consists of little else than mere notices of their subjugation by the great powers that successively ruled the destinies of Asia Minor. After living for many ages under native princes, they were first reduced by Crœsus, King of Lydia. On the fall of that monarch, their country was incorporated with the empire of Cyrus. They freed themselves from the Persian yoke only to come in course of time, along with Pontus and Cappadocia, under the power of Eumenes, one of the generals of Alexander. Then, after again enjoying an interval of independence under the government of native princes, they were again subjugated by Mithridates the Great. From the dominion of Mithridates their kingdom eventually passed into the hands of the Romans. Paphlagonia formed part of the province of Galatia, until, in the reign of Constantine, it was constituted a separate province. The chief towns on the coast were Sinope (*Sinab*), Cytorus, and Amastris (*Amaserah*). Those inland were Pompeiopolis and Gangra.

PAPHOS, the name of two ancient cities of Cyprus which were situated on the S.W. coast of the island. Old Paphos stood on a height about 10 stadia from the shore, and was said to have been founded by Cinyras, the father of Adonis. It was famous throughout the ancient world, and celebrated by the ancient poets on account of its association with the name of Venus. There the goddess is said to have come on shore immediately after she had started into life out of the sea; and there her worship is supposed to have been set up by the Phœnicians. There also were her grave and altar, which are mentioned in the Odyssey; her spacious temple, which is still seen in ruins; and her image, which was nothing else than a white, twisted, pyramidal stone. About 60 stadia N.W. from Old Paphos was New Paphos (modern *Baffa*). It stood upon the sea; and was said to have been founded after the destruction of Troy by Agapenor, the leader of the Arcadians. Although, like its more ancient namesake, it was the seat of the worship of Venus, it was best known for its good harbour. It is also notable as the place where Paul struck Elymas the Sorcerer with blindness. (See Baffa.)

PAPIAS, an early Christian writer, flourished in the beginning of the second century as bishop of Hierapolis in Asia. According to Irenæus, he was a hearer of John (probably the Evangelist), and a companion of Polycarp. A few fragments of *An Explication of the Words of the Lord* are the only specimens of his works that are extant. They are found scattered among the writings of Irenæus, Eusebius, and other authors, and are valuable for the traditions they contain regarding the Scriptures of the New Testament. The best collection of them is contained in the first volume of Routh's *Reliquiæ Sacra*, 8vo, Oxford 1846–48.

PAPIER MACHÉ. Articles in this substance are made of cuttings of white or brown paper, boiled in water, and beaten in a mortar, till they are reduced to a kind of paste, and then boiled with a solution of gum-arabic or of size, to give tenacity to the paste, which is afterwards formed into different articles, by pressing it into oiled moulds. When dry, the work is done over with a mixture of size and lamp-black, and afterwards varnished. The black varnish for these articles is prepared as follows:—Some colophony, or turpentine boiled down till it becomes black and friable, is melted in a glazed earthen vessel, and thrice as much amber in fine powder is sprinkled in by degrees, with the addition now and then of a little spirit or oil of turpentine. When the amber is melted, the same quantity of sarcocolla is sprinkled in, and the ingredients are stirred, and more spirit of turpentine is added, until the whole becomes fluid; it is then strained clear through a coarse hair bag, pressing it gently between hot boards. This varnish, mixed with ivory-black in fine powder, is applied, in a hot room, on the dried paper paste, which is then set in a gently heated oven, next day in a hotter oven, and the third day in a very hot one, and allowed to remain each time till the oven grows cold. The paste thus varnished is hard, durable, and glossy, and is not affected by moisture or even by hot liquids.

The better kinds of *papier maché* work are prepared in the following manner:—Porous paper, saturated with a solution of flour and glue, is placed in repeated layers upon a metal mould of somewhat smaller size than the required object, a drying heat of about a 100° being used between the layers, of which there are about ten for an ordinary tea-tray, but the number varies with the nature of the article. When a sufficient thickness has been attained, the shell is removed from the mould and is planed and filed to shape. Various coats of varnish are then laid on, and the article is stoved after each varnishing. The article is next smoothed with pumice-stone, and the artist then steps in and ornaments the work in bronze powder, gold, colours, &c., after which several coats of shell-lac varnish are added, and the article having been stoved at a heat of 280°, is polished with rotten-stone and oil, and is finished off by hand-rubbing.

Articles in *papier maché* are subject to two great faults, namely, inappropriateness and over-ornamentation. The manufacturer is not content to execute in this material such articles as tea-trays, screens, portfolios, ink-stands, work-boxes, &c., but he invades the domain of other materials, by executing chairs, tables, piano-fortes, &c., for which *papier maché* is not suited. The articles are also usually over-loaded with ornament; and the free use of mother-of-pearl becomes objectionable, especially when it is employed in landscapes to represent the moon, a river, or a ruined tower. In contrasting some articles in japanned ware from Japan and China, with similar articles of English make, the jury of the Great Exhibition of 1851, in remarking on the good taste of the former, and the bad taste of the latter, observed, that "vulgar forms and bad ornament are not necessarily connected with cheap manufacture."

Sharp and well-defined architectural ornaments in *papier maché* are prepared by glueing sheets of brown paper together, pressing the mass into a metal mould, and when the moulded paper has been trimmed to shape, a composition of paper-pulp, mixed with rosin and glue, is put into the mould, and the paper impression being again inserted is pressed upon the pulp composition, which permanently adheres to it. *Carton-pierre* ornaments (which are lighter and stronger than those of plaster of Paris) are made of paper-pulp, mixed with whiting and glue pressed into plaster piece-moulds, backed with paper, and when sufficiently set, are hardened by drying in a hot room. (C. T.)

PAPINIANUS, ÆMILIUS, one of the greatest jurists of antiquity, was born about the middle of the second century, and, after studying under Q. Cervidius Scævola, was appointed *advocatus fisci* by the Emperor Marcus Antoninus. A high-toned integrity, adorned with all the penetration, erudition, and sagacity of a consummate lawyer, was the quality which distinguished his character, and determined the fortunes of his career. It secured for him the confidence of the Emperor Septimius Severus; so that he was appointed in succession *libellorum magister* and *præfectus prætorii.* Yet it also brought upon him the enmity of Caracalla, the son and successor of that monarch; for this imperial fratricide felt himself rebuked by the lofty morality of the lawyer, and could not pursue his bloody career in peace until he had put him to death. The writings of Papinian attained a reputation unsurpassed by those of any other Roman jurist. He is quoted with the highest commendation in various parts of the *Code* of Justinian; and the Constitution of Theodosius and Valentinian sets him up as the chief legal authority. Further, the law students of the third year assumed the name of "Papinianistæ," and kept the first day of their session as a festival in honour of the great lawyer after whom they were called. There are 595 excerpts from Papinian's works in Justinian's *Digest.* They are extracted from the thirty-seven books of his *Quæstiones*, the nineteen books of his *Responsa*, the two books of his *Definitiones*, the two books of his *De Adulteriis*, the single book of his on this same subject, and his Greek fragment on the Office of the Ædile. Papinian is also quoted by Paulus, Ulpian, and Marcian.

PAPPUS. See GEOMETRY.

PAPUA, or NEW GUINEA. See AUSTRALASIA.

PAPYRUS (*Papyrus niloticus*, *P. Ægyptiacus*, *P. antiquorum*), a plant of the order *Triandria digynia*, and of the genus Cyperaceæ, used by the ancient Egyptians in the manufacture of paper. (See PAPER.)

PAPYRUS, the paper made of the papyrus-plant, and used by the Egyptians, as also by the Greeks, Romans, and other nations of antiquity. (See PAPER.)

PAPYRUS-ROLL, a sheet of papyrus paper, or several sheets united into one, rolled upon a slender wooden cylinder for the purpose of writing thereon letters, contracts, official acts, funereal and sacred books, historical records, and other compositions. Frail and perishable as is the papyrus-paper, very many such rolls, some of them of the remotest antiquity, have come down to us in a high state of preservation; and are commonly known under the name of *papyri.* As the Egyptian papyri, besides the high intrinsic interest which they possess, have contributed in a very remarkable way to the solution of the great problem of the hieroglyphic question, it seems necessary, although they have been cursorily noticed already under the head EGYPT (p. 444), to devote to the subject a special article, which shall also embrace the Greek papyri, and the few which have reached our time in Latin or other ancient languages.

It is impossible to fix with precision the period in Egyptian history at which the practice of writing on papyrus began; but it is unquestionably of the highest antiquity. The hieroglyphics which the extant papyri contain, judging by their form and character, belong to the time of the fourth and fifth dynasties (Lepsius, *Chronol. der Ægyptier*, p. 33); and, indeed, among the hieroglyphical characters on the monuments of that date, are found the *papyrus-roll itself*, as well as the rest of the writing apparatus. Many of the extant papyri seem certainly to belong to a very remote period. Lepsius refers the well-known papyrus which he himself has edited, under the name of *The Book of the Dead*, and which we shall have hereafter to describe, to the earliest Pharaonic times; and Bunsen agrees in this estimate of its age. Wilkinson places the Turin *Book of Kings* in the reign of the third king of the nineteenth dynasty, Rhamses II., whose name it bears upon the back; and the Rev. Dunbar Heath is satisfied that the rolls of which he has published an account, under the name of *The Exodus Papyri*, are actually contemporaneous with the events to which he supposes them to refer.

The subject naturally divides itself into three heads—Egyptian papyri, Greek and Roman papyri, and papyri of the later empire.

I. The Egyptian papyrus-rolls first came into notice in Europe when the celebrated French expedition opened Egypt, and her history and antiquities, to the researches of the learned. Since that time many collections, of greater or of less value, have been deposited in the public and private libraries and museums of Europe; and a good deal has been done towards the publication and illustration of the more important among them. They are for the most part funereal; and they have generally been found in the mummy-cases, placed between the thighs or the arms, and sometimes upon the stomach, or in the bend of the knees, of the mummy. Considerable collections of them were formed by different travellers or residents in Egypt, and they have for the most part been deposited in the several great libraries of the European capitals; the British Museum, the Bibliothèque Impériale at Paris, the Vatican, the Berlin library, the Vienna library, the library of Trinity College, Dublin, and especially the Royal Library of Turin. The first specimen of the Egyptian rolls of any real in-

Papyrus-Roll.

terest made public in Europe was printed in 1805, by M. Cadet,[1] and afterwards in a most beautifully-executed facsimile in the great French collection, *Description de l'Egypte*.[2] Since that time have appeared many most costly and elaborate specimens, to the most important of which we shall have occasion to allude; and there can be little doubt that, in the progress of Egyptian studies, and with the increased advantages which modern students possess, every fragment of interest which has been preserved will eventually find its way into print.

The papyri are found written in various characters. Of those in the Egyptian language, some are in the hieroglyphic character, but very many more are in the hieratic, and also in the demotic. (See HIEROGLYPHICS.) Some of the Egyptian papyri are in the Greek language and character. Those in the ancient Egyptian language may be divided into three classes—the funereal, the historical or literary, and those which relate to judicial, domestic, or social affairs. All these, but particularly the first class, have been found in tombs, especially at Thebes and Memphis.

(1.) The funereal papyri were the first to attract attention, from their number and the frequency of their occurrence. It would seem, indeed, that a copy of one of these papyri was regarded by the Egyptians in the light of a passport after death and a protection to the soul in its journey towards the realms of judgment. An interesting funereal papyrus, found in the collection of Trinity College, Dublin, contains a rubric to the effect, that, "if this book be recited on the earth, and this chapter be put in writing upon a person's coffin, he shall be manifested in the light, with all the honours due to him; when he goes to his house, he shall not be turned back; there shall be given to him bread, liquors, and the choicest meats on the altar of Osiris; and he shall go to the fields of Aalon."[3] Hence there was a busy trade in the production and sale of copies of these papyri. Many of those still preserved were plainly prepared beforehand for sale, blanks being left for the names and titles of the deceased, to be filled up as the occasion arose. These blanks are frequently found filled up in a hand different from the body of the document; and in some copies the blanks still appear, owing to the forgetfulness or neglect of the undertaker. In a very highly-finished papyrus in the Dublin collection, the blanks are left unfilled throughout the entire document.[4] These funereal papyri, numerous as they are, are all, in substance, copies, somewhat varied, of one common original, or of certain portions of it, the most complete copy of which now known is that preserved in the Turin Museum. The papyrus published by Cadet, and in the *Description de l'Egypte;* those published by Young in the collection of the Egyptian Society;[5] by Leemanns in the *Monumens du Musée des Pays Bas;* by Von Hammer at Vienna in 1822; by Mai in 1825; by Sankowski in 1826; by Rosellini, Salvolini, and still more recently, by Brugsch and Forshall, are all evidently drawn from that same original, although different portions are selected in each instance, and although where the same portion is repeated in two or more of the papyri, the forms of expression seem to vary considerably. It will be sufficient, therefore, to describe the nature, and briefly to indicate the contents, of the copy which is found in the Turin Museum, supplying from other papyri some additional illustrations and pictorial representations. This remarkable papyrus was first examined by Champollion, who found it to contain twice as much as that published in the *Description de l'Egypte*. Champollion regarded it as a copy of the funereal ritual of the Egyptians, an opinion from which Lepsius dissents, but without much apparent reason; although, perhaps, the title which the latter writer proposes, *Das Todtenbuch*, "The Book of the Dead," describes its character more exactly. Champollion, after a careful study of the text, divided it into four parts, according to the supposed order of the subject, each of which he subdivided into chapters. Dr Lepsius, however, who copied the entire in 1836, and published it in a most elaborate facsimile in 1842,[6] proposes a different and apparently more intelligible division into chapters, which is now generally adopted. Each of these chapters (which are 165 in number) has, generally speaking, a title and an illustrative picture prefixed; and the division of the chapters is commonly indicated by two lines, and by the words *hè re* or *ki re* ("another chapter"). The first fifteen chapters appear in themselves to form a connected whole, and are entitled *Ha' t em re u nu her em heru en Hes-iri*—("beginning of the chapters of the appearing of the light of Osiris"). This first portion of the *Book of the Dead* is regarded by Lepsius as the most ancient, and indeed as the germ of the entire, out of which all the subsequent parts have grown as developments or additions. It occurs in many papyri, and the illustrative vignettes are generally the same, although differing much from each other in the richness and beauty of execution. In these vignettes are represented the funeral procession, the mourners, the boat with the bier of the deceased sailing upon the sacred river, the train of domestics bearing libations and other offerings; and finally, the deceased himself in the act of adoring the sun. Then follows a series of mystic representations bearing upon the destiny of the deceased, and of invocations to the god Thôth, in which he is entreated, as "Thôth who justified Osiris in the sight of his mercies," to "justify Osiris[7] Anfanχ, even as he justified Osiris in the presence of the great Tetmessu."[8] The vignettes which follow represent the act of placing under the protection of the several deities before whom the deceased is thus justified, the several limbs or parts of the body of the deceased—his head, eyes, mouth, heart, arms, hands, feet, legs, stomach, &c.; and the various combats which he is obliged to undergo. Next come pictures of his deliverance from various perils; of the refreshments which are vouchsafed to him; of his worshipping various deities; of the reunion of his soul with the body; of his passage through the fields of Tmé (the Egyptian Elysium), in which he is represented as ploughing, sowing, reaping, thrashing, and lastly, rowing across the infernal river a boat containing the cakes which he has made; of his subsequent journey to the mystic region called Rosattou, and his arrival at the hall of the Two Truths, where is represented his denial to the forty-two assessors of Osiris, of forty-two distinct offences with which he is charged before them, and in which is placed the remarkable scene of the Psychostasia, or weighing of the soul in the scale of justice. Most of the papyri contain pictures of this very interesting monument of the Egyptian creed, varying slightly in detail, but all exhibiting the same great features. At the left side of a great hall, with the well-known frieze and pillars, is seated Osiris, who is represented with his habitual whip and crook, and generally (though not in the

Papyrus-Roll.

Turin papyrus) with the tablet of Mà, the goddess of justice, upon his breast. On the right enters the deceased, above whose head appears in hieroglyphics the usual invocation of Osiris. He is received by the goddess of justice, Mà, who is often represented in the two-fold character of reward and punishment. In the centre stands a pair of scales, in one of which Anubis is represented placing as a weight a little figure of the goddess Mà, while in the other scale the deceased is shown placing a heart-shaped weight (sometimes with the word *keti*, "heart," inscribed upon it), the emblem of his own works, good or evil, during life. The well-known hawk-headed figure adjusts the balance; above sits the forty-two assessors of Osiris, sometimes with the deceased kneeling before them; while Thôth, the justifier of Osiris, and of all the just, is represented writing down the result of the trial. After this most interesting picture come the purgatorial scenes, and those in the Hall of the Propylons, which are exceedingly curious. The deceased demands to be admitted. "I will not allow thee to enter," begins the lintel of the door, "till thou tell me my name." "——" (not satisfactorily interpreted) "is thy name." "I will not allow thee to enter by me," says the left post of the door, "until thou tell me my name." "Hanti-n-tmè (Pillar of Truth) is thy name." Similar demands are made in succession by the right post, the threshold, the lock, the key, the bolt, the floor, &c. Without pursuing this farther, however, it will be enough to say that many other equally curious representations, illustrative, not only of the creed of the Egyptians, but of scenes of their every-day life, are found in these singular relics of ancient Egypt; and they have supplied a most valuable key to much that was obscure in the manners and customs of this remarkable people.

Another of the funereal papyri, but of later date, has still more recently been published by Dr Brugsch at Berlin, under the title of *Sai an Sinsin*.[1] It is in the hieratic character, and furnishes a very valuable supplement to Lepsius' *Todtenbuch*. It will be enough to say, that in these two publications, which are both accompanied by translations and elaborate annotations, the reader will find all the latest and best information on both the general subject of funereal papyri, and on all the details which they ordinarily present.

(2.) The historical Egyptian papyri have come more recently into notice, but they have contributed to throw a great deal of light on many difficult questions of Egyptian history and chronology. The most important of these are the Turin *Book of Kings*, *The Campaign of Rhamses the Great against the Scythians and their Allies*, and the so-called "*Exodus Papyri*."

The history of the Turin Papyrus of the Kings is a curious one. It originally came into the possession of the Turin Museum in the collection of Signor Drovetti, which was purchased by the Piedmontese government; but this particular papyrus had been so injured by time or by neglect, that it seemed little better than a mass of fragments. Champollion, however, while he was inspecting the Egyptian antiquities of the Turin Museum, at once perceived its value, and carefully selected, from a mass of papyrus fragments among which it lay in a confused heap, all the scraps which contained the names of kings, putting them together in the best order which he could devise. This work, however, has since been done over again with exceeding skill and judgment by Dr Seyffarth, who, by carefully examining with a microscope the fibres of the several fragments, has succeeded in restoring the papyrus to a tolerable degree of completeness. This manuscript was printed by Lepsius in his *Auswahl*; but, as that copy did not contain the inscription on the back, the papyrus has since been published entire by Sir Gardner Wilkinson.[2] Its contents have already thrown light on many points, both in the native monuments of Egyptian history and in the collateral indications supplied by the Bible narrative: and, although there is much in this and all other Egyptian records which disappoints inquiry, it is hardly possible to overrate the importance of the study in itself, or the hopes which may not unreasonably be entertained from a more complete and systematic investigation. This papyrus appears to have been written in the time of Rhamses II. It does not contain the name of any king later than the eighteenth dynasty.

Papyrus-Roll.

The *Scythian Campaign of Rhamses the Great* is a papyrus which originally formed part of M. Sallier's (of Aix) collection. It was published in 1835[3] by Salvolini, the pupil of Champollion. It has unfortunately but little of the strictly historical character, consisting in great part of encomiums of Rhamses, bombastic addresses to his soldiers, dialogues of the king with the gods, and similar rhetorical materials; but it is nevertheless highly curious and characteristic.

The "Exodus Papyri," of which the Rev. Dunbar Heath has published an account,[4] are naturally, from their subject, even more interesting, inasmuch as he considers these remarkable compositions so many contemporary collateral evidences of the Bible history of the exodus of the Jewish people. Much remains still to be done for their full elucidation; but enough is stated by Mr Heath to create a deep interest in the subject. These papyri, which originally formed part of the Sallier and of the Anastasi collections, present many most striking coincidences with the Mosaic narrative. The most important of them is a letter or report addressed by Enna, a scribe, to his superior officer, who had commissioned him to carry out an order that a certain slave people should be allowed four days of holiday for the observance of their festival, complaining that this order had been resisted by a certain Tahpanhes. Now, according to Mr Heath, in these curious documents we meet with a Jannes mentioned five times, a Moses twice, a Balak the son of Zippor at a place called Huzoth, with the word Hebrew, and with the "feast of passing the dead." We find also that a people, among whom a Moses was leader, marched towards Palestine by the route of Tasacarta, Megdol, and Zoar; that they were connected with the names Midian and Aram; that there was a contest at the place of a great water-flood; that an enslaved Aramæan people, located about Tahpanhes, met great opposition from the governor in celebrating the four days' feast at the beginning of their year; that a Moses is again named as cattle-owner among them; that a royal or noble youth is described as meeting a sudden and mysterious death; that a royal order is immediately issued for the hasty departure of a people, for their feast of passing the dead; and that miracles are named as performed by their leader in the palace of Lower Egypt. (Pp. 57–8.) And although the coincidences may not be complete, nor the evidences entirely satisfactory, yet they are quite enough to create an interest in the subject of the very deepest kind. Several other papyri in the British Museum and other collections are historical. In the *Select Papyri of the British Museum* (London, 1844) there are four; and Lepsius (pp. 33–4) mentions two others in Berlin, and a third in his own possession.

Of strictly so-called literary papyri among the Egyptians little is known; but we may mention one very curious one, of

[1] *Sai an Sinsin; sive Liber Metempsychosis veterum Egyptiorum. E duabus Papyris funebribus hieraticis signis exaratis edidit, Latinè vertit, notas adjecit*, Henricus Brugsch, Berlin, 1851.

[2] *The Fragments of the Hieratic Papyrus at Turin, containing the Names of Egyptian Kings, with the Hieratic Inscription at the Back*, by Sir J. G. Wilkinson, London, 1851.

[2] *Campagne de Rhamses le Grand contre les Scheta et leurs Alliés*, Paris, 1835.

[3] *The Exodus Papyri*, by Rev. D. J. Heath, with Introduction by Miss Fanny Corbaux, London, 1855.

which an account is given in the *Revue Archeologique* for 1852–3 (pp. 385–97). It is the story of two brothers, Anepou and Patou, one of whom is the Egyptian counterpart of Joseph in the Bible history. He is tempted by his brother's wife in exactly the same words employed by the wife of Potiphar, and on his resisting her seductions, is denounced by her to her husband. The subsequent narrative, which it would be too tedious to detail, is a strange medley of the natural and supernatural; but the whole piece presents in a very curious light not only the domestic usages of Egypt, but the popular notions which then prevailed as to the interposition of the gods in the affairs of men.

Under the head of Egyptian papyrus literature, may perhaps be mentioned the well-known and valuable fragment of Homer on papyrus, which was found in one of the tombs at Thebes. It is of course in Greek, but as having been found in an Egyptian tomb, may be considered as Egyptian.

(3.) The Egyptian papyri which relate to civil or judicial affairs are generally in the enchorial character: they relate for the most part to sales or transfers of property, houses, lands, tombs, &c., the particulars of which they describe in most curious detail. The subjects of many of them may to some appear tedious and unimportant; but in reality it is to them that Egyptian antiquarians have been indebted for most of the details of the judicial processes of Egyptian law, as well as of many of the particulars of the private life of the Egyptians.

II. By far the most important Greek papyri are those of Herculaneum, which have been elsewhere described. (See HERCULANEUM.) Unhappily the condition of these rolls is so lamentably defective that at best only fragments can be hoped from their decipherment; and it must be confessed too, that the books which have been hitherto discovered, and of which the *Volumina Herculanensia* contain the remains, are not of a nature to make the loss a subject of much regret. There are two of them, the titles of which, as bearing upon Homer, might seem calculated to create an expectation of something which might give us an idea of the principles of criticism which then prevailed; but they are miserably meagre and unsatisfactory; and the same may be said even of what bears upon the Epicurean philosophy, although the author, Philodemus, was a follower of that sect.

But the strictly Egyptian papyri in the Greek language are no less valuable, as illustrating the manners and customs of the Egyptians, than those in the Egyptian language; and they have the additional advantage of being at once perfectly intelligible, and of serving as a key to the enchorial language of Egypt. Several collections of these papyri have been published; the most notable are those of Amedeo Peyron, whose labours as an editor of palimpsest literature have been described in another place. (See PALIMPSEST.) He published in 1826 a considerable collection[1] with a very interesting introduction and notes; and a few years later, he added to these a commentary on some papyri selected out of a similar though smaller selection from the museum of Vienna,[2] which had been published by Giovanni Petrettini.[3] These papyri, which are all of the class already described, are most curious and highly important for the student of Egyptian domestic and social antiquities. A selection from the Greek papyri of the British Museum has been published by Mr Forshall;[4] but, as the text only is given, unaccompanied by illustrative notes, this publication is far inferior in interest to that of Amedeo Peyron, or to a similar one of his nephew, Bernardino Peyron, printed several years later. An additional item in the value of these papyri, and one which was early appreciated by Young in his hieroglyphical studies, is the fact, that many of them are but the Greek transcripts of the enchorial original of the deed of sale, contract, or judicial procedure, and therefore serve, to some extent at least, if not as a translation, at all events as a guide to the sense of the original.

III. The papyri in Latin and other ancient languages are not of much interest. Of the rolls in Herculaneum, many were in Latin; but unhappily the folds of all these were so firmly agglutinated that they went to pieces in the attempt to unrol them. One scrap alone, in hexameter verse, has escaped, and is published in the second volume of the *Volumina Herculanensia*. It is a fragment of a poem on the battle of Pelusium, and is ascribed by the editors to Rabirius, a writer of whom little else is known.

Of the later period, a copy of St Augustine's Letters is the only Latin relic on papyrus of any interest. A few specimens of charters and similar records on papyrus are given by Silvestre in his *Palæographie Universelle*. In the same work also are one or two papyri in the Syriac and Arabic languages.

(Besides the works cited above, see *Sammlung Demotish, Griechischer Eigennamen Agyptische Privat leute, aus Inschriften und Papyrus-rollen zusannumgestellt*, von Ernest Brugsch, Berlin, 1851. See also *Lettre a M. E. De Rougè au Sujet de la Decouverte d'un MS. Bilingue Papyrus en Ecriture Demotico-Egyptienne et en Grec cursif de l'an* 114 *avant notre ete.*, Berlin, 1852, by the same author.) (C. W. R.)

PARA (in full, *Santa Maria de Belem do Gram Pará*), a town of Brazil, capital of a province of the same name, stands on the right shore of the estuary of Pará, or south arm of the Amazon, which is here 7 miles wide, about 70 miles from the Atlantic. The streets are straight and well paved, crossing one another at right angles; and the houses are well and substantially, some even elegantly, built of stone. They are not generally high, few having more than two stories, and many of them only one. There is a large and handsome cathedral, and several fine churches. The Jesuits' seminary, now partially used as an episcopal palace, and the governor's palace, are among the finest buildings in the town. There are two convents, and the buildings of a third are now used as barracks. Pará has also a college, several schools and hospitals, a botanic garden, a theatre, and a court of law. The anchorage of the city of Pará is capacious and perfectly safe, being rarely exposed to strong winds, except momentary squalls, and varying in depth from 7 to 3¼ fathoms, or less. With the exception of two large shoals at the entrance of the river, the approach is practically unobstructed, there being abundant breadth of channel, varying from 7 to 11 fathoms in depth. The entrance-channel at the mouth of the river is deep and clear for a W.S.W. course, and there is little or no difficulty in entering by daylight; but for sailing-vessels of large draught the outlet (which is through another channel) is not quite so safe, as it is narrow and much shallower, and as the wind sets directly into it. A redoubt in front of the palace overlooks the anchorage, and a small fort 4 miles below the town commands the approach. The commerce of the port is very considerable; it was formerly the source whence most of the countries in the world were supplied with India-rubber; and though the discovery of that article in the East Indies, Africa, and in other parts, has somewhat diminished the quantity exported, yet it still constitutes one of the chief staples of the trade of Pará. The quantities exported in 1856 were,—to Great Britain, 1,984,940 lb.; to the United States, 2,444,580 lb.; and to other countries, 367,309 lb. The export of cocoa, however, is at present greater than that of India-rubber. It is chiefly sent to France, where a great demand was created for it during

[1] *Papiri Græci Taurinensis Musæi*, 2 vols. 4to, 1826.

[2] *Papiri Greco-Egizi di Zoide del Museo di Vienna*, 1828.

[3] *Papiri Greco-Egizi del Museo Imperiale di Vienna*, 1826.

[4] In 1839.

the recent war. The quantities of this article exported in 1856 were,—to France, 5,260,155 lb.; to other countries, 103,255 lb. There are also exported large quantities of Brazil nuts, rice, sugar, cotton, dye-woods, &c. The most important articles of importation are hardware, calico, and soap, all of which are chiefly obtained from the United States. The following table exhibits the shipping entered and cleared, as well as the total value of the imports and exports since 1851:—

Year.	Vessels entered		Imports.	Vessels cleared.		Exports.
	No.	Tonnage.		No.	Tonnage.	
			L.			L.
1851	81	14,194	238,876	82	14,825	383,280
1852	88	15,457	240,029	85	14,693	274,214
1853	113	18,370	392,676	111	18,131	516,651
1854	114	19,777	367,906	111	19,157	662,336
1855	100	18,765	267,484	104	19,909	318,920
1856	92	18,782	332,602	90	18,479	408,725

The climate of Pará, though hot and liable to thunderstorms, is very healthy for Europeans. Pop. estimated at 28,000, of whom about 4000 are slaves.

PARÁ, a maritime province of Brazil, of which the above town is the capital. It lies between Lat. 9. S. and 4. 30. N., Long. 45. and 64. W.; and is bounded on the N. by the three Guianas and the Atlantic, E. by the provinces of Maranhao and Goyaz, S. by that of Matto-Grosso, and W. by that of Alto-Amazonas; area, 1,155,253 square miles. On the northern frontier it is separated from Guiana by a range of mountains, and from these the ground gradually slopes downwards to the bed of the Amazon, which traverses the country nearly due E. On the other side of this river the surface again rises as it approaches the watershed between the Amazon and the Rio de la Plata; but there are no very great heights in this direction. Except a few small streams, the Amazon is the only river in Pará that falls directly into the sea; but it receives many large tributaries in this province, among which are the Madeira, forming part of the western boundary, the Tapajoz, the Chingua, and the Tocantines, which joins the Pará or southern arm of the Amazon. The mineral wealth of the province is considerable, though hitherto it has been entirely neglected. Gold, iron, quicksilver, and copper among the metals, as well as diamonds, salt, coal, &c., have been found in various parts of the province; and some of them in large quantities. The soil is fertile, and the surface of the country is covered in some parts with vast and rich plains, and in others with dense, luxuriant forests. Comparatively few tracts have been brought under culture, and in these rice, coffee, cotton, sugar-cane, &c., are raised. The principal exports and imports of the province have been already noticed in speaking of the town of Pará, through which all the trade is carried on. Pop. (1856) 207,400.

PARÁ, or "Father of Waters," a name originally applied to the Amazon, but now restricted to the southern arm of that river, which receives the Tocantines from the S. It has a length of about 200 miles, and a breadth at its mouth of 40. It is at this mouth of the Amazon that the influence of the tide is most conspicuous, producing at spring tides a huge wave 15 feet high.

PARABLE (*παραβολή, a comparison*, from *παραβάλλειν, to compare, to collate*), denotes in general any discourse expressed in figurative, poetical, or highly ornamented diction. Thus it is said, "Balaam took up his *parable*" (Num. xxiii. 7); and "Job continued his *parable*" (Job xxvii. 1). Under this general signification it is used in Scripture to denote—1*st*. An obscure or enigmatical saying, as in Ps. xlix. 4; lxxviii. 2. 2*d*. A fictitious narrative, invented for the purpose of conveying truth in a more engaging form than that of direct narration. Of this sort is the parable by which Nathan reproved David (2 Sam. xii. 2, 3), that in which Jotham exposed the folly of the Shechemites (Judg. ix. 7–15), and that addressed by Jehoash to Amaziah (2 Kings xiv. 9, 10). To this class also belong the parables of Christ. 3*d*. A type or emblem, as in Heb. ix. 9, where παραβολή is rendered in our version *figure*.

Parables or fables are found in the literature of all nations. They were called by the Greeks *αἶνοι*, and by the Romans *fabulæ*. It has been usual to consider the parable as composed of two parts,—viz., the *protasis*, conveying merely the literal sense; and the *apodosis*, containing the mystical or figurative sense. It is not necessary, however, that this second part should be always expressed. The excellence of a parable depends on the propriety and force of the comparison on which it is founded, on the general fitness and harmony of its parts, on the obviousness of its main scope or design, on the beauty and conciseness of the style in which it is expressed, and on its adaptation to the circumstances and capacities of the hearers. The parables of the Old Testament are admirable specimens of this species of composition. Witness those of Jotham (Judg. ix. 7–15), of Nathan (2 Sam. xii. 1–14), of Isaiah (v. 1–5), and of Ezekiel (xix. 1–9). But the parables of our Saviour claim pre-eminence over all others, on account of their variety, appositeness, and beauty.

(See Gray, *Delineation of the Parables*, 1777; Bulkley, *Discourses on the Parables*, 1771; Collyer, *Discourses on the Parables*, 1815; Kromm, *Homilien uber die Parabeln Jesu*, 1823; Unger, *De Parabolis Jesu*, 1828; Bailey, *Exposition of the Parables*, 1829; Schultze, *De Parabolis Jesu Christi*, 1827; Lisco, *Die Parabeln Jesu*, 1832; and Trench, *Notes on the Parables of Our Lord*, 7th ed. 1857.)

PARACELSUS, PHILIPPUS AUREOLUS THEOPHRASTUS BOMBASTUS *von Hohenheim*, a famous alchemist and enthusiast of the sixteenth century, was the son of a physician, and was born in 1493 at Einsiedeln, a small town of the canton of Schwitz, distant some leagues from Zurich. Although his regular education seems to have been but small, a keen and general curiosity was his characteristic from an early age. While still a mere boy he made himself an adept in the juggling of the magician, the spells of the conjuror, and the arts of the alchemist. He then set out, a penniless vagabond, to search through the world for knowledge. There was scarcely a country in Europe which the feet of the strolling schoolman did not visit. His cool, self-possessed countenance was seen at the universities of Germany, France, and Italy, picking up stray scraps of medical knowledge. His voluble tongue was heard in the villages of Spain, Portugal, Prussia, and Poland, wheedling mystical lore from monks, quacks, jugglers, and old crones. He appeared among the lonely mountains of Bohemia and Sweden, inspecting the labours of the miners. He was even seen accompanying the son of the Khan of Tartary to Constantinople, to learn from a Greek the secret of the tincture or elixir of Trismegistus.

It is not known at what period he returned to Germany; but it appears that, about the age of thirty-three, several remarkable cures which he wrought on persons of distinction gave him such celebrity, that in 1526 he was, on the recommendation of Œcolampadius, called to fill the chair of physic and surgery in the university of Basil. Here Paracelsus commenced his career by burning publicly in the hall the works of Avicenna and Galen; assuring his auditors, that his shoe-ties knew more than these two physicians, that all the universities, and all the writers united were less instructed than the hairs of his beard, and that he should be regarded as the sole monarch of physic. The novelty of his doctrine, the confidence with which he spoke of his success, the power to which he pretended of prolonging his life and curing the most inveterate diseases,

and the use of the vulgar tongue in his lectures, made him very popular. Many students crowded to hear his prelections. Many patients came to consult him. Among others, Erasmus, who had long suffered from gravel, applied to him; and this circumstance led to a correspondence (which has been preserved) between these two men, who enjoyed such opposite kinds of celebrity. But even at Basil people soon began to discover that the new professor was an impudent and presumptuous quack. Scarcely had a year elapsed when his prelections were deserted. As soon as the novelty wore off, his jargon was found to be incomprehensible, and his empiricism a mere cloak for ignorance. The sottishness of his life also became notorious. Rarely did he appear in his lecture-room without being half-drunk, and seldom did he dictate to his secretaries except under the influence of wine. If called to visit a patient, he first soaked himself with liquor. He had the custom of sleeping in his clothes, and sometimes passed whole nights in low taverns drinking with boors. At length he happened to assail a magistrate with the grossest abuse, and dreading punishment for such an outrage, found himself under the necessity of decamping from Basil towards the end of the year 1527. The close of Paracelsus' career, like the beginning, was spent in ceaseless wandering. He appeared at Colmar in 1528, at Nuremberg in 1529, at St Gall in 1531, at Pfeffers in 1535, and at Augsburg in 1536. He then made some stay in Moravia, where he once more compromised his reputation by the loss of some distinguished patients, and was in consequence obliged to take his departure for Vienna. From that capital he passed into Hungary, and in 1538 appeared at Villach, where he dedicated his *Chronicle* to the states of Carinthia, in gratitude for the favours which they had bestowed on his father. But his stay here appears to have been short; for in 1540 we find him at Mindelheim, whence he proceeded to Saltzburg, the ultimate term of all his wanderings. On the 24th of September 1541 he died in the hospital of St Stephen at that place, in the forty-eighth year of his age, and in a state of abject poverty, notwithstanding he pretended to the possession of the double secret of transmuting metals and prolonging life even to the extent of several centuries.

The medical reputation of Paracelsus is not founded on any actual discoveries, but on the importance which he gave to pharmaceutical chemistry. By his bold language and still bolder practice, he dispelled the prejudices of the Galenical physicians against the productions of the laboratory. Mercury was introduced into general use by him as a cure for the venereal disease. He also seems to have been the first who used opium both as a narcotic and as a remedy for gout, fever, and similar diseases. Paracelsus is likewise notable for his general services to experimental science. How great these services were is described in Dissertation First, part i., chap. i.

Paracelsus published very few works in his lifetime, and those which are attributed to him exhibit so many contradictions that several of them have been ascribed to his disciples. It would be a useless waste of space to enumerate the titles of all his works: we shall therefore content ourselves with indicating the different complete collections. 1. The German editions, Basil, 1575, in 8vo; ibid. 1589–1590, in 10 vols. 4to; and Strasburg 1603–1618, in 4 vols. folio. 2. The Latin editions, *Opera Omnia Medico-Chymico-Chirurgica*, Frankfort, 1603, in 10 vols. 4to, and Geneva, 1658, in 3 vols. folio. 3. The French editions, *La Grand Chirurgerie de Paracelse*, Lyons, 1593 and 1603, in 4to; and Montbéliard, 1608, in 8vo. (See Adelung, *Histoire de la Folie Humaine*, tom. vii.; the *Biographie Universelle*, article Paracelse; and Sprengel, *Histoire Pragmatique de la Médécine*, tom. iii.)

PARADISE (παράδεισος), the term which, by long and extensive use, has been employed to designate the garden of Eden, the first dwelling-place of human beings. Of this word the earliest instance that we have is in the writings of Xenophon, nearly 400 years B.C., and his use of it answers very closely to our English word *park*, with the addition of gardens, a managerie, and an aviary. The real origin of the word, however, is to be sought neither in the Greek nor the Hebrew, but in the languages of Eastern Asia. "Paradise," says Fürst, is "a name common to several oriental languages, and especially current among the Persians, as we learn from Xenophon and Julius Pollux; Sanscrit, *pardeesha;* Armenian, *pardez;* Arabic, *firdaus;* Syriac, *fardaiso;* Chaldee of the Targums, *pardeesa.*" (*Concord. V. T.*, p. 920, Leipsic, 1840.

(For an outline of the various geographical theories which have been advanced respecting the vexed and indeterminable question of the situation of Paradise, see Appendix to Rosenmüller's *Biblical Geography of Central Asia*, by Rev. R. Morren, 1836.)

The term soon began to be used metaphorically for the abstract idea of exquisite delight, and was transferred still higher to denote the happiness of the righteous in a future state. (See Eden.)

PARADOX (παράδοξος, *contrary to opinion*), a proposition seemingly absurd, because at variance with some ascertained truth, or with some commonly-received opinion, but which nevertheless may, on strict scrutiny, prove to be correct.

PARAFFINE. See Peat.

PARAGUANA, a peninsula of Venezuela, in the province of Eoro, projects into the Caribbean Sea, and is connected with the mainland by a long and narrow isthmus; length, about 40 miles; breadth, 35. It is hilly in the centre, and gradually slopes towards the sea; and it is chiefly occupied by pasture-ground.

PARAGUAY, a republic of South America, lying between S. Lat. 27. 18. and 21. 20., W. Long. 54. 23. and 58. 46.; and bounded on the N. and E. by Brazil, and on the S. and W. by the Argentine Republic. Its form is nearly that of a parallelogram: its length, from N. to S., about 416 miles; average breadth, 180; area, 72,160 square miles. Paraguay forms a sort of inland peninsula, being surrounded on three sides by the River Parana, and its tributary the Paraguay, which joins it at the S.W. corner of the state. The centre of the country is traversed from N. to S. by a mountain-chain called the Sierra Anambahy, which separates itself into two at its southern extremity, forming the valley of the Tibicuary, an affluent of the Paraguay. The whole of the rivers of this country flow either into the Paraguay or the Parana; and as the central mountain-chain which divides their waters is in no place more than 100 miles from either of these rivers, the streams of the country are more remarkable for number than for magnitude. By far the longest and most important of these is the Tibicuary already mentioned, which has a tortuous course, and waters the southern portion of Paraguay. This southern region is a rich and beautiful country, presenting a striking contrast to the adjacent parts of the Argentine Republic. It consists of broad valleys and plains affording excellent pasturage, undulating slopes, and hills covered from top to bottom with magnificent forests. The soil here is very fertile; and cultivation is more extensively carried on in this district than in any other part of the interior of South America. White cottages may frequently be seen in the midst of trees surrounded by cultivated fields; but even here it is only scattered patches of ground that are tilled. Portions of this southern region are occupied by extensive marshes and broad but shallow lakes. The northern and eastern part of Paraguay is but little known. It seems to be a rugged and mountainous country, densely covered with forests, and watered by numerous rivers, which have many rapids and waterfalls. In the N.E. there is a branch of

dirty; but they contain some fine stone fountains, and many of the houses have a picturesque aspect. It contains several Greek churches and mosques. Pop. 5000.

PARANA. See PLATA, *Rio de la*.

PARANAGUA, a town of Brazil, province of São Paulo, 180 miles S.S.W. of São Paulo. It contains several churches; a court-house; a town-hall, with a prison attached to it; a custom-house, formerly a Jesuits' college; several schools; a theatre; and an hospital. The harbour is good, and capable of receiving large ships. An active trade is carried on in timber, flour, rice, pulse, Paraguay tea, cattle, &c. Pop. of the district, 7000.

PARAPET. See Glossary to ARCHITECTURE.

PARAPHERNALIA is a legal term, derived ultimately from the Greek παράφερνα, signifying "that which a bride brings over and above her dower," and applied to the personal attire and ornaments of a wife, which, under certain restrictions, are considered as her own peculiar property. (See HUSBAND AND WIFE.)

PARAPHRASE (from παραφράζω, *I add words*) is the rendering of an author's meaning in words different from, and generally more abundant than, his own. If it is a foreign language which is paraphrased, the paraphrase, as a loose, free translation, is opposed to the metaphrase, or literal rendering of the original. The paraphrase, in short, partakes alike of the version and the commentary, without belonging exclusively to either. The word is sometimes extended to poetical as well as prose translations of an author's meaning. Such are those sacred songs known as *paraphrases*, which are poetical renderings of certain passages of Scripture.

PARASANG (Gr. παρασάγγης; Persian *ferseng*), a lineal measure among the Persians, frequently alluded to by Greek writers. Owing to the original indefiniteness of itinerary distances, it seems to have differed considerably at different times. The estimate of its length most commonly received is that given by Herodotus, Suidas, Hesychius, and Xenophon, and which is equivalent to about 30 Greek stadia, or 3¾ English miles. Rödiger, in Ersch u. Gruber's *Encyclopadie*, takes the word to be connected with the Persian *seng*, a stone, in allusion to the stones which were placed at certain intervals on the public roads in that country to indicate distances, after the manner of our mile-stones.

PARASCENIUM. See Glossary to ARCHITECTURE.

PARASITE. In modern times, we have various examples of terms which once had a religious signification being applied to a secular or profane interpretation. A pilgrimage to Rome was, in its origin, a circumstance of earnest gravity, but such iniquity was at last connected with it, that to "go Roming," as it used to be written, was a phrase employed to depict the course of life of idle and impure vagabonds of either sex. Again, a crusade to the "Sainte Terre" had a pious end in view; but, in support of expeditions thither, the land became covered with lazy mendicants, who lounged from village to village begging or exacting alms in support of the enterprise in the Holy Land. Thence these fellows, and ultimately others of similar quality, acquired the name of *Saunterers*. In like manner, when the once solemn cavalcade to the shrine of Thomas à Becket at Canterbury, became nothing more than groups of gay riders, who trotted easily down to the ancient city, with set phrases of profession, and certain practices of a different tendency, the tone and the pace gave two words to our language which still survive,—namely, "cant" and "canter,"—the first was to talk, and the second to ride, like the pilgrims who visited the great shrine near which lay some at least of the bruised limbs of the hero of his day, and the "saint" of after times.

It has been something the same with the term *parasite*, which, in its origin, signified an official of considerable dignity in the temples of the heathen gods, but which afterwards designated a miserable class of professional diners-out,—men

> "Whose flanks grew great,
> Swell'd by the lard of others' meat,"—

and which name and class did not expire till a few years ago, when there ceased to appear among French advertisements intimations of certain individuals ready to enliven, for duly named fees, wedding banquets; to serve as *seconds* in duels, which were followed commonly by joyous breakfasts; and who were always ready dressed at the dinner hour, prepared to go to any house where, without them, there would be "thirteen at table."

The *parasite* and the *fanatic* have encountered a similar destiny. The latter, as noticed in the article FANATICISM, was originally he who "performed the duties of a temple, the religious personage, the priest, who in the temple was the organ of the god." Subsequently, the ancients called those "fanatics" who passed their time in temples, and being often seized by a kind of enthusiasm, as if inspired by the divinity, exhibited wild and antic gestures. At present, wherever a blind and obstinate fury in the furthering of any object has extinguished reason, judgment, and well-directed zeal, *there* is fanaticism. The parasite has as dignified an origin as the fanatic, but the word itself has become subject to more comic yet equally contemptuous applications. In the palmy days of heathenism he too was an official in various temples, but especially in those of Apollo and Minerva, and at the shrine of the divine hero Hercules. The Greek words παρα and σιτος, signify literally "near" and "corn," and they bore the further meaning, idiomatically, of "messmate." The parasites of Greece have been compared with the *epulones* of the Latins, and in *one* respect some similarity may be found. It was the custom of the Romans, not only on certain festive occasions, but also when danger threatened the commonwealth, to give a grand banquet (*epula* or *lecti sternia*), in some convenient temple, to the principal gods to whom they acknowledged allegiance. The statues of the deities were placed on lofty couches, and before these marble guests a sumptuous banquet was spread, provided and solemnly served by the *epulones*, the duly-ordained clerical stewards at such ceremonies. In the ranks of the priesthood, the *epulo* seems to have been of equal dignity with the *augur;* and Pliny the Younger, thinking neither of the offices unworthy of his acceptance, once applied to Trajan to be nominated to one or the other, on the first vacancy.

The parasite, like the *epulo*, was an officer of the temple tables, but after another fashion. It was his duty to select the corn for the sacrificial banquets, and probably for the beasts that were to be sacrificed. He occasionally gathered it from the "religiously and devoutly disposed," or he chose it from the crops which flourished on the temple lands. When the corn was thus got together, the parasites distributed it to the various temples within their limits of office, within which limits some were of more exalted dignity than others. Their trouble or zeal was rewarded by one-third of the ox sacrificed. The other two-thirds went to the priests, and nominally to the deities. The Latin *epulo* was appointed to the office by nomination of the head of the government. The Greek parasite was generally elected; he was not even chosen by lot. At Athens twelve individuals were selected by the citizens as *worthy*, and then the richest and the most noble of these were elected as the most *efficient*. In some cases there were certain tribes privileged or taxed to furnish two parasites yearly; and we also find particular families required, when necessary, to furnish a parasite from among their members. In no case could the person elected or summoned refuse to accept the office. A symptom of reluctance was immediately met by an irresistible magisterial process of compulsion, under which the individual repaired at once to his well-known official residence, the *Parasiteion*.

In some parts of Greece there existed families from whom those then important officials, the heralds, were chosen. From these same families were selected two parasites who served in the temple of Apollo in Delos, during a year. At the shrine of Hercules the parasites performed monthly sacrifices with the priests; and in some temples of Apollo we find Acharnensian parasites exclusively engaged, whose distribution of offerings gave one-third of the best bulls to the games, and divided the remainder between the parasites and the priests. Offerings of fish were accepted by the former from the fishermen, and were similarly divided; and in Athens one-sixth of every bushel of barley was set apart for the table in the temple at which the Athenian citizens feasted.

It was not alone to the temples that parasites were attached. Each archon had two, and each polemarch one, in his suit. In course of time the fashion or custom prevailed whereby other officials of a certain dignity appointed parasites in their households; and from this may probably be dated the commencement of the decline of this singular branch of the priesthood in public respect. In this last employment the parasites were, in the households to which we allude, something like what the ordinary family chaplain was in English country mansions at the close of the seventeenth and beginning of the eighteenth centuries,—namely, the flatterer, the servant-companion, and the butt of the head of the establishment. As regular attendants at banquets, the parasites are supposed to have first appeared in Sicily, a locality famous for its feasts, and for the superexcellence of its cooks. Subsequently the profession extended and degraded itself, and its members became the prey of the comic poets and the laughing-stock of the people. The parasites of the comic drama were undoubtedly caricatures of well-known living characters. They were to be found under various appellations, but the parasite proper was ordinarily accoutred in a black robe; the mask worn by the performer had a comic expression; the nose was flattened, looking in outline almost like an ace of clubs; and the ears hung down, to indicate the frequency of the blows dealt to the poor buffoon.

The professional parasite, who lived at the cost of his patron for the hour, supped or dined wherever a taste of his quality was required; and at wedding-feasts presented himself without invitation, as knowing that he would be welcomed for his jests. Some of the sharpest of these were showered, with something harder than words, on the heads of the guests who omitted to laugh at the jokes of the master of the feast. When his own comicality was not to the taste of the latter, the guests, in their turn, would unceremoniously kick the sorry fellow into the street, and, by tearing to rags his only dress-suit, render him unfit for company till he had repaired the damage. With a good share of facetiousness, impudence, and sensuality, he could contrive to lead a luxurious yet a precarious style of living. For succulent repasts and a fair reward, he not only expended jokes, but submitted to any indignity. He was hailed by coarse names, often buffeted, and when not too drunk himself, exercised the office of carrying out the more drunken. From always being present at feasts, he received the distinguished title of "sauce;" occasionally, to give him a mock dignity, a patron would lend him a slave, and, in return, the parasite was always ready to serve as a bully, and more or less cruelly assault such persons as had the ill luck to be out of favour with his employer.

These parasites were huge feeders; but some of them, in order to procure engagements the more readily, advertised their abstemiousness and their social qualities in combination. Chiefly, and with reason, they boasted of their powers of flattery. They would imitate the infirmities of their rich employers; and there was no habit of the latter ever so filthy or horrible which they would not praise as something highly pleasant and worthy of laudation. Human nature shudders at the thought of what these officials sometimes witnessed at table, and which they readily imitated or extravagantly eulogized. They professed to have a patron in heaven in Ζεὺς ὁ φιλιος; but their profane blasphemy was astounding, some of them not hesitating to offer to princely patrons the divine worship which was due only to the gods. Even some of these august patrons could object to or scorn such homage as this. We have an example in the case of Alexander: when taking medicine with childish reluctance, Philarches, his parasite, exclaimed, "What must mortals suffer when they swallow physic, if you who are a divinity can hardly do it." The idea of a god drawing health from an apothecary's phial was too much even for Alexander, who declined to accept the apotheosis, and called Philarches "an ass."

There were two families in Salamis in which the offices of parasite and spy were hereditary: these were the Gerginoi and the Promalangoi. The former did the dirtier work, and reported to the latter the private conversations of citizens, which the Promalangoi at the table of the Anactes or princes communicated with much flattery to their masters. It was an evil fashion which has not expired on the Continent.

The old practitioners gloried in their calling. "Truly," exclaims a parasite, in a fragment of Antiphanes, "since the most important business of life is to play, laugh, trifle, and drink, I should like to know where you would find a condition more agreeable than ours!" On one occasion, the condition was one of great dignity, though purchased by treachery. The three parasites, or "adorers and flatterers" of Cnopus, King of Erythra, after murdering their master, gained possession of the kingdom by a *coup d'etat*, the success of which saved them from the merited fate of assassins, and raised them to the rank of heroes. They administered a ferociously-abused sort of justice at the gates of the city; violated every law of man, of nature, and of God; boasted of their popularity, when they had slain, imprisoned, or otherwise silenced every opponent; attired themselves gorgeously in effeminate costumes; and daily sat down to dinner, in diadems that dazzled the company by their lustre. When these strange rulers felt, or said they felt, light of heart, it was the duty of the city to exhibit a corresponding joy, and if the circumstances of the hour induced them to put on a gravity of deportment, duly appointed officers went through the city with many-lashed whips, and flogged the people into wearing expressions of devout horror! It was the remark of the present Emperor Napoleon, when writing in the *Progrés de Calais* against the repressive laws of Louis Philippe, that "every despotic government falls by the very measures which it takes to support itself." It was so with this extraordinary government of the parasites. The Erythrians ultimately plucked up their courage, and just when the authority of the parasites seemed most firmly established by the suppression of all liberty, the exasperated and long-suffering people arose in irresistible wrath, and swept these tyrannical *parvenus* into Hades.

Thus, it will have been seen that the parasites, although they seized on royal authority, were incompetent to retain it. Having exhibited them in so many varieties of condition, there remains little to be added, save to recommend those who are curious on the subject to study the comedies of Plautus. In *them* the parasite figures as necessarily as the impudent valet in a Spanish comedy. It is worthy of remark, that Plautus jokingly calls the parasites *poetæ*, as being addicted to lying; and it is singular that the Gauls named their poets "parasites," because of their fondness for good living. Previous to the era of printing, the professional parasite, with his jests, anecdotes, and histories, was a sort of living circulating library. Saturion, one of the examples in Plautus, professes to be tranquil in his

mind, because, as he remarks, he can provide for his daughter by bequeathing to her his rich collection of jokes and dinner-stories. "They are all sparkling Attic," he exclaims, "and there is not a dull Sicilian anecdote among them." This reference to his daughter suggests the idea that there were female parasites, as at Christian courts there were not only male but official female "fools." However this may have been, it is certain that the parasite, in his more servile condition, was a personage, the fire of whose attachment blazed up or faded according to that in the kitchen of the Amphitryon by whom he was patronized. In short, throughout life, the parasites worked only for the banquet and the wine-pot; even after death some of them longed for libations, as appears from the epitaph on the parasite Sergius of Pola:—

Si, urbani, perhiberi vultis
Arenti meo cineri,
Cantharo piaculum vinarium festinate.

If you've any regard for this carcase of mine,
Be so good as to wet it with hogsheads of wine!

Athenæus, in the 34th chapter of his 6th book, has cited what may almost be termed a multitude of authors, each of whom affords some illustration of the parasite in his dress, bearing, manners, morals, objects, virtues, vices, or unutterable nastiness and atrocity. Instead of selecting a specimen from a book which, even in an English form, is now accessible to all, it will perhaps be preferable to resort to a lively painter uncited by the diligent grammarian of Naucratis, and conclude with the following sketch from Martial, as translated by Hodgson:—

When from the bath, or hot or cold, you come,
The kind Menogenes attends you home.
When at the courts you play the healthy ball,
He picks it up adroitly, should it fall.
Though wash'd, though dress'd, he follows where it flies,
Recovers and returns the dainty prize,
And overwhelms you with civilities;—
Calls for your towel and, though more defil'd
Than the foul linen of a sickly child,
He'll swear 'tis whiter than the driven snow;—
Comb your lank hair across your wrinkled brow,
And, with a tone of ecstacy, he'll swear,
"Achilles had not such a head of hair."
Himself will bring th' emetic to your hand,
And wipe the drops that on your forehead stand,
Praise and admire you till, fatigued, you say,—
"Do, my good friend, do dine with me to-day!"

(J. D—R—N.)

PARASITES, or PARASITIC PLANTS. See BOTANY.

PARATI, a seaport-town of Brazil, province of Rio de Janeiro, at the head of a small arm of the sea, in the Bay of Angra dos Reis, 100 miles W.S.W. of Rio de Janeiro. It is regularly laid out and well built, containing several churches and schools, a town-hall, and an hospital. An extensive trade in rum, sugar, coffee, rice, &c., is carried on. Pop. 10,000.

PARCÆ (Greek, Μοῖραι), the Fates, were variously represented in classical mythology as the daughters of Erebus and Nox, or of Jupiter and Themis. Their number was generally supposed to be three: *Clotho* the spinner, *Lachesis* the disposer of lots, and *Atropos* the inevitable. They are described under many different aspects by many different authors. The following are some of the principal traits of their character as it has been developed by the combined representations of various ancient writers:—The three dread sisters held the universe entirely under their control, and executed all the purposes of nature with an inexorable decision which regarded neither gods nor men. In particular, they had unlimited power over the thread of human destiny. Clotho held the distaff, Lachesis twirled the spindle, and Atropos cut the thread. They also presided over other great events in the life of men. For example, on nuptial occasions they foretold in chants the fortunes of the newly-wedded pair; and when any dark crime was perpetrated, they hunted down the offender with retribution. The Fates were generally represented by the poets as old women, lame, withered, savage, and ugly. There were shrines erected to them in many parts of Greece.

PARCHIM, a town of Mecklenburg-Schwerin, on the left bank of the Elde, 21 miles S.E. of Schwerin. It contains a town-hall, churches, and schools. In the neighbourhood there are medicinal springs and bathing establishments. Weaving, distilling, and the making of tobacco, straw hats, &c., are carried on, as well as a considerable trade. Pop. 6450.

PARCHMENT, the skins of animals so prepared as to render them proper for being written upon, or used in covering books. The skins of most animals are adapted to the manufacture, but as the better kinds are used in making leather, sheep-skins are preferred. The finer kind of parchment, known as *vellum*, is from the skins of calves, kids, and dead-born lambs. The stout parchment of drum-heads is from the skin of the wolf, although that of the ass or calf is sometimes used; the parchment of battledores is from the skin of the ass; and that used for sieves from the skin of the he-goat.

The word *parchment* comes from the Latin *pergamena*, the ancient name of this manufacture, which is said to have been taken from the city of Pergamus. Eumenes, the king of that place (who reigned B.C. 197–159), has the honour of the invention; although, in reality, that prince appears rather to have been the improver than the inventor of parchment. According to Diodorus, the Persians of old wrote all their records on skins; and the ancient Ionians, as we learn from Herodotus, made use of sheep and goat skins in writing many ages before the time of Eumenes. Nor need we doubt that such skins were dressed for the purpose after a manner not unlike that in which our parchment is prepared, though probably not so artificially.

The manufacture of parchment is begun by the skinner, and finished by the parchment-maker. The skin having been stripped of its wool and placed in the lime-pit, the skinner stretches it on a wooden frame, called a *herse*, consisting of four bars perforated with holes, in each of which is a peg. Pieces of twine, extending from the edges of the skin to the pegs, retain the skin in an extended state, in which the skinner pares it with a knife, called, from its shape, a *half-moon knife*. This being done, it is moistened with a rag; and powdered chalk being spread over it on the flesh side, the skinner takes a large pumice-stone, flat at the bottom, rubs over the skin, and thus scours off the flesh: this is called *grinding*. He then goes over it again with the knife, moistens it as before, and rubs it again with the pumice-stone without any chalk underneath, by which means the flesh side is considerably smoothed and softened. He then again passes the knife over it, which is called *draining*. The flesh side being thus drained, by scraping off the moisture, he in the same manner passes the knife over the grain side, and then scrapes the flesh side again. This finishes the draining; and the more it is drained, the whiter it becomes. The skinner now throws on more chalk, sweeping it over with a piece of lamb-skin which has the wool on; and this smooths it still farther. It is then left to dry, and when dried, taken off the frame by cutting it all round. The skin, being thus far prepared by the skinner, is taken out of his hands by the *parchment-maker*, who first, whilst it is dry, pares it on a *sumner*, or calf-skin stretched in a frame, with a sharper instrument than that used by the skinner; and, working with the arm from the top to the bottom of the skin, takes away about one-half of its thickness. The skin, being thus equally pared on the grain side, is again rendered smooth by being rubbed with the pumice-stone on a bench covered with a sack stuffed with flocks, which leaves the parchment in a

condition fit for writing upon. Should any small holes appear in the skin, they are stopped by cutting the edges thin and laying on small pieces of parchment with gum-water. The parings taken off the skins are used in making glue, size, and the like.

The green parchment used in book-binding is coloured by means of verdigris, for which purpose thirty parts of crystallized verdigris, and eight parts of cream of tartar, are boiled in 500 parts of distilled water; when the solution is cold, four parts of nitric acid are added. The parchment is moistened with a brush; the colour is spread evenly over it; and, when dry, polish is given by means of white of egg or gum-arabic. (C. T.)

PARDON, in *Criminal Law*, is the remitting or forgiving an offence committed against the king.

Law, says Beccaria, cannot be framed on principles of compassion to guilt; yet justice, by the constitution of England, is bound to be administered in mercy. This is promised by the king in his coronation oath; and it is that act of his government which is the most personal and most entirely his own. The king condemns no man; that unpleasant task he leaves to his courts of justice; the great operation of his sceptre is mercy. His power of pardoning was said by the Saxons to be derived *a lege suæ dignitatis;* and it is declared in Parliament, by stat. 27 Henry VIII., c. 24, that no other person has power to pardon or remit any treason or felonies whatsoever, but that the king has the whole and sole power thereof, united and knit to the imperial crown of this realm.

It is impossible to lay down any abstract rules for the administration of mercy. Each case must be judged of according to its own circumstances.

That human nature is such as in the aggregate to need control, no one who is acquainted with it will deny; and there appears to be no other method of controlling mankind but by general laws; but then, through the natural imperfection of human affairs, they may be cruel in one case while they are just in another. Cases may likewise occur where the sentence of the law, without its execution, will answer every purpose which could be expected from it, and where the execution of it would be extreme cruelty, although it might in strict language be called justice, because in conformity with the letter of the law. Yet though such cases may and do often occur, it would be absurd to abolish any of those laws which the security of civil society has required; and therefore the only mode of regulating their operation in criminal matters seems to be the system of absolute or conditional pardons.

It is possible to define a particular crime, and to annex a particular punishment to the commission of it; while the moral guilt of criminals may vary. The real guilt consists not in the external action, but in the motives which prompted to it. Definite law, however, cannot always make such distinctions; besides, after the sentence of the law is pronounced, circumstances may emerge which present the case in a very different aspect from what it previously bore. Then there are what may be called accidents of the case, which could not be previously defined. To particularize and define, in laying down a law, every mode of an action which imagination can conceive, or which experience has shown us may happen, is utterly impossible; and therefore it seems equitable that there should be a power vested somewhere to modify and control, or even to discharge altogether, the judgments of the law in criminal cases; and that power in this country is judicially vested in the sovereign in council, or in Parliament by acts of indemnity. It is not exercised so as to affect the private rights of third parties; and therefore, though the manslayer may be pardoned, the private right of the next of kin to damages is not thereby prejudiced.

PARDUBITZ, a town of Bohemia, circle of Chrudim, stands at the confluence of the Elbe and the Chrudimka, 13 miles S. by W. of Königgrätz. It has a castle surrounded with walls and ditches, an imperial stud, linen factories, copper and iron forges, and a population of 4150.

PARÉ, AMBROISE, the father of French surgery, was born at Laval, in the province of Maine, in 1509, and died in 1590. A collection of his works was published at Paris in 1561, and was afterwards frequently reprinted. Several editions have also appeared in German and Dutch. Among the English translations was that of Thomas Johnson, London, 1634. (For an account of Paré's professional career and services, see SURGERY.)

PAREDES-DE-NAVA, a town of Spain, in the province of Palencia, stands on a pestilential lake, 16 miles N.W. of Palencia. The parish church of St Eulalia contains some carvings by Alonso Berruguete, who introduced the *cinque-cento* style into Spain. There are also a town-hall, prison, nunnery, several schools, and an hospital. Manufactures of woollen stuffs and serges are carried on. Pop. 6014.

PAREJA, JUAN DE, a Spanish painter, was by descent a mulatto slave, and was born at Seville in 1606. His knowledge of art was acquired in a singular manner. Becoming at an early age the bond servant of Velasquez, he was employed to do the menial work in the studio of that great artist. The daily sight of the creations of genius coming out in form and beauty on the blank canvas kindled within him an inextinguishable love of art. During the day he eagerly watched his master's hand, and during the night he stealthily practised with his master's brushes. Thus, after many years of clandestine assiduity, he attained to no mean skill in painting. Equally singular with this manner of acquiring excellence was Pareja's manner of divulging it. Knowing that the king, Philip IV., would visit the studio on a certain day, he hung up a picture of his own among his master's, with its face to the wall, and loitered close by to wait for the result. The king turned the picture, and admired it; Velasquez in surprise disclaimed all knowledge of the painter; and then the slave, dropping down on his knees before his Majesty, confessed his secret studies, and obtained on the spot not only forgiveness, but also freedom. Pareja proved himself a grateful freedman. During the remainder of Velasquez's life he continued in the house in the two-fold character of an attendant and a scholar. Then he transferred his services to his master's daughter, and remained with her till his death in 1670. A large picture by Pareja, entitled "The Calling of St Matthew," is in the royal gallery of Spain, and is remarkable for its successful imitation of the colouring and manipulation of Velasquez. (Stirling's *Artists of Spain.*)

PARENT AND CHILD. Children born in wedlock, or within a competent time after its dissolution, are legitimate. In some countries legitimacy is conferred on children by the marriage of their parents to each other subsequent to the birth of the children (see HUSBAND AND WIFE); or, in certain circumstances, is admitted where no marriage was, or could lawfully be, entered into. Children born in other circumstances are called illegitimate. By the law of England, children born before marriage are incapable of succeeding to their father's English property except by will, even although they were born in a country which recognises legitimation by a subsequent marriage; and the same rule exists in reference to children born after the marriage of a British subject to his deceased wife's sister, though it take place in a country where such a marriage is lawful. In Scotland, a subsequent lawful marriage removes the legal stain of bastardy. Scotch institutional writers are not agreed as to the principle on which it does so. Some suppose that, by a legal fiction, the marriage is held to have occurred prior to the birth; while others, on better grounds, think it results from the expediency of converting what was

at first an irregular into an honourable relationship. The former necessarily hold, that if either of the parents contracted an intermediate marriage with a third party, the fiction was destroyed, and the children remained illegitimate; while the latter, discarding the fiction altogether, maintain that when the intermediate marriage is dissolved, the Scotch law permits the parents to marry, for the express purpose of putting an end to illicit intercourse, and of conferring legitimacy on the children previously born. This last may now be regarded as the law of Scotland, unless the birth be the result either of incestuous or (probably) of adulterous intercourse. To confer the privilege of legitimation, the subsequent marriage must take place when the father has his domicile in Scotland, or in a country which holds, in this respect, a similar law; for if he be domiciled at the time of the marriage in England, or in any country, the law of which, like that of England, does not recognise such a mode of legitimation, the children will continue to be regarded as bastards in Scotland, and disqualified to succeed as heirs to their father. So entirely does this mode of legitimation in Scotland depend on the father's domicile at the date of the marriage, that although both the birth and the marriage occur in Scotland, if the father be domiciled in England at the time of the marriage, the children born previously to the marriage remain illegitimate. On the other hand, and on the same principle, though both the birth and the subsequent marriage take place in England, yet if at the time the father's domicile be in Scotland, the children will be regarded as lawful children in Scotland; and it is probable that they would be so regarded though only the subsequent marriage occurred when the father's domicile was in Scotland. A father domiciled in England at the time of his marriage there to a woman by whom he has previously had children, and afterwards acquiring a Scotch domicile, cannot confer legitimacy on such children by his again going through in Scotland the ceremony of marriage with their mother.

The obvious result of this difference between the law of England and Scotland is the incongruous one, that if a father domiciled in Scotland die intestate, leaving estates in both countries, and two sons, both by the same mother, the one born before and the other after his marriage with her, the son born before the marriage will succeed to the Scotch estate, and the son born after it will succeed to the English estate, each in the character of being his father's eldest lawful son in these countries respectively. If the one of these sons who was born before the marriage had died before his father, leaving a child, such child, as representing its father, acquires all the rights which its father would have acquired in Scotland had he survived, to the exclusion of the son first born after the marriage, and his heirs; and this although the marriage does not take place till after the death of the son who was born before it.

In all these cases of legitimacy by subsequent marriage, it is necessary that the husband acknowledge himself to be the father. The acknowledgment, if distinct, need not be in any specific form. It may even be inferred from the conduct of the father,—such as his presence at the child's baptism, or receiving the child into his family and treating it as his own.

A question has arisen whether, in any case, children can be legitimate where their parents went through the ceremony of marriage, but could not have been lawfully married? If a man and woman go through the ceremony of marriage with each other, knowing that they are disqualified by relationship, their children will remain illegitimate, even although the legality of the marriage may not have been called in question during the lifetime of the parents. But what if the parents acted in blameless ignorance? Of course, on the discovery of the disqualification, the marriage may be annulled as being unlawful; but if it were entered into innocently, the legitimacy of the offspring is secured by the good faith of the parents. Accordingly, in Scotland, the good faith of both parents was held to save the rights of the children in a case which occurred more than a hundred years ago. The jurist who reported that judgment gave it as his opinion, that the good faith of either of the parents would have led to the same result; and this point became the subject of litigation within the present century, but unfortunately the claimant died before judgment could be pronounced. This doctrine is not new. At a period prior to the Reformation, when impediments to marriage were absurdly extended, it was sometimes discovered, after children were born, that their legitimacy was doubtful; and it became more reasonable to support the legitimacy than to bastardize children who were begotten in utter absence of any intention to violate the law. After the Reformation the Commissary Court in Scotland acted in accordance with this view.

The presumption in favour of the legitimacy of children born in wedlock is so strong, that it can only be overcome by evidence leading to the conclusive conviction that the husband is not the father. The presumption is against the legitimacy if the parents were entirely separated between eleven solar and six lunar months antecedent to the birth. The most open adultery of a married woman will not of itself bastardize her offspring, unless it be rendered credible by other facts and circumstances that her husband is not the father. Even the united declaration of both husband and wife, that the husband is not the father, though always important, is insufficient, because they may be acting collusively and falsely for improper purposes. But if, in addition to the manifest adultery of the wife, with the admission, probably, of the paternity by a third party, there are circumstances which seem to infer that a child was not lawfully begotten, then the declaration of the parents will become matter of grave consideration. Looking to the whole conduct of the married pair, prior and subsequent to the birth, the House of Peers has on more than one occasion found it morally impossible to believe in the legitimacy of a child, and has therefore given judgment against it, even where the physical possibility was not absolutely excluded. In one of these cases, the married pair dwelt near each other, but then the birth was studiously, and for a considerable period successfully, concealed from the husband, while the paternity was acknowledged by another man with whom the woman had been intimate, and who bequeathed his whole property to the child. Some circumstances extinguish the plea of legitimacy at once; as, if the child were a Mulatto, the husband being a white man. No reliance is placed on family resemblance, as being too fanciful; though in one case the House of Peers heard an argument partly founded on that circumstance.

We shall now briefly notice,—1*st*, The duties of parents to their lawful children; 2*d*, The powers of parents over their children; 3*d*, The duties of children to their parents; and 4*th*, The duties and obligations between parents and illegitimate children.

1. *The Duties of Parents.*—In every civilized country a father is obliged, if he be able, to support his children, and to train them to be able to support themselves. This is the dictate of nature. It is scarcely possible, however, for a court of law to interfere with the details of the father's management, unless it be obviously cruel or immoral. In regard to education of children, it has been thought that, except in extreme cases, "there is no farther obligation than what nature has implanted" in the father's breast. If the father be dead, and the child is in the custody of tutors, courts of law find no difficulty in interfering, wherever it appears that the child is being reared in a manner unsuitable to its position and prospects. When children have attained an age at which, under ordinary circumstances,

they should be able to support themselves, the father's obligations cease, unless they become disabled by accident or disease; and then the father, if able, is bound to provide them with necessaries only, and nothing more. If a father, being able, refuses to aliment his children, whereby they become chargeable to the parish, he is punished by fine and imprisonment, under the statute 8 and 9 Vict., c. 83, § 80. It is not the policy of law to tempt children to lead idle lives. A gentleman of fortune, however, will hardly be relieved of his obligation to support his son on his being qualified to become a lawyer or a physician, because, by training his son to any such profession, the father virtually undertakes to maintain him until he can support himself by it. Still more, if a wealthy father were not to train his son to any profession or trade whatever, he raises against himself an obligation to support him beyond majority, if he be otherwise destitute. If the father be incapacitated to support his minor children, his duties fall first on the mother, if she have independent means of her own, and next on the father's nearest ascendant, going backward according to their ability, rather than on the parish, with a right of relief against the father of the children if he afterwards become possessed of means. But a grandfather is not bound to support his indigent daughter-in-law. The obligation of support ceases in the lower ranks when children are able to support themselves by labour; and in the upper ranks, when they obtain the means,—as when a son gets a commission in the army,—unless he is thereafter incapacitated by some blameless cause, as a stroke of palsy, in which case the father is the sole judge as to how and where the support shall be given. It has been decided by the House of Peers that the amount of aliment in such a case "is, support beyond want, and all that is beyond that, is left to parental affection." Under all circumstances, a child drawing profits from any source is bound to bear his own expenses so far as he is able, but he is not bound to repay what his father may have expended on him out of any property which he may subsequently succeed to or acquire. If a wealthy father neglect his duty to a disabled son, a third party supplying him with necessaries has a good action against the father for payment; but not the lender of money, unless he prove that it was truly expended in providing what should have been provided by the father. If, in advancing money to a son, to enable him to purchase a commission or to enter into business, the father take a voucher for it, or enter it in his books against the son, a debt rather than a donation will be implied. If a father become bankrupt, his obligations to support his children are altogether subordinated to his obligations to pay his other lawful debts; so that children cannot be ranked like ordinary creditors on their father's estate, excepting in certain cases where a credit has been created in their favour, as by an antenuptial contract of marriage. If an heir succeed to an estate through his father, and the latter have left children in poverty, the obligations of the father are transferred to the heir. This results, not from relationship, because a man is not bound in law to support his brother or sister, and still less more remote relatives, but from the heir representing, and taking possession of the estate of, his ancestor. In such a case, the liability of the heir does not exceed the liability of the ancestor, had he survived. Every such case, however, must be governed by its own circumstances. For example, if a father die, leaving several sons and daughters, and an estate clogged with debt, the daughters, like their brothers, must betake themselves to some employment; while the heir of a large unburdened estate is liable to support his sisters, if they have not been trained to work, until their marriage. On that event, the obligation expires.

The law of England does not prevent a father from disinheriting his children. The Roman law allowed him to do so only if he could show a sufficient reason. In Scotland the father can disappoint his heir of his unentailed lands by the expedient of giving them to the person he desires to prefer, in terms implying a *present* conveyance, under reservation of his (the father's) liferent, and power at any time to revoke the deed. Such a deed, if unrevoked, receives effect at his death.

2. *The Powers of Parents.*—At one period the Roman law set no limits to the parental authority; and though it subsequently did so, it never interfered with the father's right to the whole of his child's earnings. By the laws of England and Scotland the father is entitled to the custody of his children, even though he may have violated his conjugal duties, except in the extreme cases already hinted at; and he has a right to inflict that moderate degree of chastisement which is necessary to secure obedience, and to promote the real welfare of his minor children. After their majority, if they require assistance, he may exact residence in his family as the condition of granting it. So long as they reside in family with their father, he has a right in England to the profits of their industry, and in Scotland to such profits to the extent of the expense which they occasion to him. The father is tutor to his children while in puberty, and their curator thereafter until their majority. In the former capacity, he acts for them; and in the latter, with them. No legal proceedings are necessary to invest a father in these offices; and he is not required, like a stranger, to take the oath to act faithfully, nor to find security for his intromissions, unless he be insolvent. No deed by a minor is binding if it be disapproved of by the father,—not even articles of apprenticeship,—although to such a deed his consent may be implied from his tacit acquiescence for a length of time to his child remaining in the service. A minor, although living independently on his own fortune, cannot grant leases, remove tenants, or sell or burden his lands, without his father's express consent; because the parental guardianship is designed to supply the immaturity of the child's judgment and experience. Without such consent, the minor's bond or bill for borrowed money affords no ground of action, after his majority, to a greater extent than the sum which the creditor can prove was applied to the profitable uses of the minor. Unsuitable furnishings to a minor never afford a good ground of action against him; and if he have no means of his own, even furnishings which are suitable in their own nature constitute a debt, not against the minor, but against his father, unless the father have previously sufficiently supplied the minor. It is the duty of third parties to make inquiry before giving credit to a minor. Where the minor is not residing in the family of his father, these rules may not be so strictly enforced against the merchant; but in no case will an action lie for unsuitable furnishings, nor for necessaries too frequently given, unless they may eventually become available to the minor. A minor is not entitled to restitution for the loss he may have suffered from his unsuitable purchases with cash, the father or guardian being to blame for having allowed him the command of the money, whereby the merchant may have been thrown off his guard. And if a minor be so nearly major that the merchant might be mistaken as to his age, and he fraudulently imposes on the merchant by pretending that he has attained majority, and thus gets credit, the minor, by his fraud, will create a debt against himself for which he may be justly sued in majority.

The father's right of administration in reference to any estate to which his children may succeed by the will of a third party, is excluded wherever the granter either gives the administration to another, or simply excludes that of the father. In this last case, the court will appoint a guardian in reference to such estate. The marriage of a minor daughter puts an end to the guardianship of her father, and

Parent and Child.

transfers it to her husband; and it is excluded wherever the child has an action at law against the father, and wherever the father has an interest adverse to the child: the court in these cases appoints a curator.

One cannot here help noticing a remarkable difference between the laws of England and Scotland in this respect, that in England the consent of the father is required to prevent the marriage of a minor from being invalidated, while in Scotland such consent is not required. Somewhat inconsistently with itself, the law of Scotland requires the father's approval of very unimportant transactions on the part of a minor, and yet allows a girl of twelve years of age and a boy of fourteen to enter into the contract of marriage, on which the happiness of their lives may depend, without the concurrence or advice of any guardian whatever.

In England and in Scotland both sexes are enfranchised at the age of twenty-one.

3. *The Duties of Children to their Parents.*—These are very strongly written on the heart, though it is not always easy for human laws to enforce them. Children should yield to their parents obedience in youth, and affection and reverence through life. The maltreatment of parents by children is justly punished as an aggravated offence. Some of the duties of children are not extinguished even though their parents may be the reverse of exemplary. For instance, children are bound at all times, if able, whatever the character or conduct of their parents may have been, to support them when indigent, in return for the support which they (the children) received in infancy; and this altogether independent of the question, whether they succeeded to any property through their parents or not. The obligation of a child to support, if able, his indigent mother, does not depend on his representing his father, as it does in the case of brothers or sisters. It is a natural obligation, incumbent on himself according to his ability, and which the law will enforce.

4. *Of the Duties and Obligations between Parents and Illegitimate Children.*—These are very inferior to those above referred to. At one time, the bastard was treated as if he had been a delinquent. For example, unless he had heirs of his own body, he could not make a testament without letters of legitimation from the crown; but this disability was removed by the statute 6 Will. IV., c. 22. At present, a bastard cannot succeed to his father, except by will. In England the rights of an illegitimate child "are only such as he can acquire, for he can inherit nothing, being looked on as the son of nobody."

In Scotland, as in England, so far as succession is concerned, the illegitimate child is regarded as having no father; and therefore, on the one hand, he is not his father's heir, and on the other, the father has no right to the custody of, neither has he a right to act as administrator at law to, the unfortunate infant. It follows that the father cannot appoint tutors or curators, or guardians of any kind, to his illegitimate child, unless he leave property by special deed to him; in which case he can only appoint guardians in reference to the property left, on the same footing with a person leaving property by will to a stranger. The law compels the father, when the paternity is ascertained, to contribute along with the mother for the support of the bastard; the amount, which is only for "support beyond want," varying a little with the rank and condition of the parents, and never for a longer period than until the child attain an age at which it is able to work for itself; the mother till then being entitled to the custody of the child. The father can only exclude the mother's right to the custody by proving that she is an improper person for such a trust, or is guilty of cruelly maltreating the child. Even her right to the custody expires on her illegitimate son becoming seven, and her illegitimate daughter ten years of age; and then the father may, if he wish it, make his right to have the custody a condition of his giving farther aliment, unless the mother can show (which at these tender years is not always difficult) the existence of circumstances sufficient to justify an extension of her right. Practically no aliment is awarded by law after bastards have reached twelve or sixteen years. If the father be dead, his executors cannot at any period demand the custody from the mother. The father is not liable to third parties for any debts which the mother of illegitimate children may contract on account of their upbringing; and on the other hand, he cannot claim any portion of the gains which may be acquired through their talents or industry. But if they be residing in family with their father, he may take such gains to the extent of the expense which they occasion. So little is there of mutual obligation between these parties, that if the illegitimate child make no claim on the father, the father has no power whatever over the child; and the illegitimate child is not liable, though he be able, to support his indigent father. The mother, however, stands in a very different position. The relationship between her and her illegitimate child is at least indisputable; and therefore the child is bound, if able, to support her when in poverty, according to the rules by which lawful children are bound to support their mother. For the same reason, though a bastard does not succeed to his father's estate, he does so to his mother's. A man is not bound to support his son's bastards. Failing their father and mother, they must be supported in infancy by the parish of their mother's settlement. The Poor Law Act, 8 and 9 Vict., c. 83, § 80, renders a father liable to fine not exceeding L.10, or imprisonment not exceeding 60 days, who leaves a bastard, acknowledged or proved to be his, to become chargeable on the parish. (M. L.)

Parent-Duchatelet || Parga.

PARENT-DUCHÂTELET, ALEXIS-JEAN-BAPTISTE, a sanitary reformer, was born in Paris in 1790, and was educated for the medical profession. After practising for some time as a doctor in the French capital, he directed his attention to the subject of public health. Actuated by pure philanthropy, and undeterred by any considerations of personal comfort and health, he visited all those places where noisome effluvia were daily killing their unconscious victims. Common sewers, tobacco manufactories, pyroligneous acid factories, burying-grounds, and dissecting-rooms, all came under his scientific inspection, and were described to the public in a great number of pamphlets. His last investigation was upon the prostitution of the capital. A report of it was published in 1836, the year in which he died.

PARGA, a town of European Turkey, in Albania, stands on a rocky peninsula on the shore of the Mediterranean, nearly opposite the island of Paxo, 47 miles S.W. of Janina. The streets are narrow and dirty; and the ground on which the town is built is so steep, that from the sea the houses look as if they stood on the top of one another. On the summit of the hill is a small but strong castle, from which a fine view may be obtained along the sea-coast and into the adjacent country, which is fertile and beautiful, abounding in olives, gardens, and citron groves. Parga has a harbour, defended by a small fortified island; and carries on a considerable export trade in oil, wine, fruit, and tobacco. It has played a part of some importance in history since the beginning of the fifteenth century. It maintained its independence, under the protection of Venice, from this period till the fall of the Venetian power in 1797, when it was for a short time garrisoned by the French. Ali Pasha, the governor of Albania, besieged it in 1814; and as the French would not defend them, the inhabitants applied for aid to the British, who took possession of the fortress. Parga was finally given up to Turkey by the treaty of 1817; but the inhabitants, not wishing to come under the Ottoman sway, migrated to Corfu and Paxo. The town was then occupied by the Turks. Pop. 4000.

PARHELIA. See CHROMATICS, METEOROLOGY, and OPTICS, part viii.

PARIA, GULF OF, an inlet of the Atlantic Ocean, on the coast of Venezuela, between the island of Trinidad and the mainland. Its form is nearly rectangular; and it is about 100 miles long by 40 broad. On the N. it is separated from the Caribbean Sea by a peninsula about 70 miles long, projecting from the continent, and terminating in Cape Punta de la Peña, or Paria. Between this headland and Trinidad, about 20 miles off, there are three rocky islands, forming four straits, the widest of which, called the Dragon's Mouth, lies nearest the mainland, and is about 6 miles across. A strong current runs northwards through all the straits, and the tides are also very powerful; so that ships can only enter with a strong breeze. The southern entrance, about 10 miles wide, between Cape Punta Icacos in Trinidad and the delta of the Orinoco, is so obstructed by a sand-bank as to leave only a narrow passage for ships. This channel is called the Serpent's Mouth. The depth of the gulf varies from 3 to 30 fathoms, and the anchorage is everywhere good; so that it forms one of the best harbours in the world.

PARIAN CHRONICLE. See ARUNDELIAN MARBLES.

PARIAS, or PARIAHS, a word derived from the name *Parriar* in the Deccan, is employed to designate one of the best known and the most degraded of the impure classes of the Hindus, amounting, it is said, to one-fifth of the whole population of Hindustan. They act as scavengers, porters, and hostlers, and generally sell themselves, with their wives and children, to the farmers, who treat them with the utmost severity. They belong properly to no caste, and are supposed to be descended from original occupiers of the soil of India, long since overcome by foreign invasion. They live apart from the other inhabitants, who hold them in great abhorrence, and subject them to the meanest and most degrading drudgery.

PARIMA, SIERRA, a chain of mountains between Venezuela and Brazil, extends in a S.W. direction from the western extremity of the Sierra Pacaraima, between N. Lat. 4. and 6. 30., W. Long. 64. and 67. They seldom rise higher than 1800 or 2000 feet from the sea; and many of the summits are only 500 or 600 feet in height. In geological structure, the base of the mountains is believed to be of granite, while trap and quartz rocks are also met with. Many of them are bare and rocky, or covered only with grass. The rivers Orinoco and Parima take their origin in this range; the latter flowing first E., then S., and falling into the Rio Negro, an affluent of the Amazon.

PARINI, GIUSEPPE, an eminent Italian poet, was born in the district of Bosisio, in the Milanese territory, in 1729. Although brought up in the midst of poverty, and compelled to earn a scanty livelihood by copying manuscripts, he cultivated his poetical faculty with distinguished success. In 1752 he published a volume of anacreontic poems, a book which showed a remarkable lyrical talent; and in 1763 he produced the first part of his *Giorno*, a work which described in a fine vein of irony the frivolous occupations and insipid amusements of an Italian nobleman's day, and which raised the author to the position of one of the greatest moral poets of his native country. This success was the means of placing Parini in several high public offices at Milan; and he was thus enabled to appear to great advantage in more characters than that of a poet. In the chair of belles lettres in the Palatine schools, and in the chair of eloquence in the College of the Brera, he proved himself to be a clear, precise, learned, and successful teacher. In the office of magistrate, to which he was appointed by Bonaparte, he also showed all the liberal-minded sagacity and cool intrepidity of one of the great citizens of classical times. The death of Parini took place in 1799. His works were published in 6 vols. 8vo, Milan, 1801-4; and in 2 vols. 8vo, Milan, 1825.

PARIS, the capital of France, situated on the river Seine, about 110 miles in direct distance from its mouth, in N. Lat. 48. 50. 49., E. Long. 2. 20. 15. It is in the department of the Seine, of which it is the chief town, and is distant about 210 miles S.S.E. from London, and 159 S.S.W. from Brussels.

Paris takes its name from the Parisii, a Gallic tribe, whose chief town, called by themselves *Loutouhezi* (*i.e.*, a dwelling surrounded by water), and by the Romans *Lutetia*, stood on the island now known as La Cité. It is first mentioned in history as the place where, in B.C. 54, Julius Cæsar convoked an assembly of the Gallic tribes. In the following year, when these tribes revolted under Vercingetorix, the Parisii were among the foremost to take up arms. Though they made a desperate resistance, and set fire to their city to save it from falling into the enemy's hands, they were finally subdued; and in the distribution of Gaul, were incorporated in the province of Lugdunensis Quarta. For 400 years after this date the name of Lutetia is hardly mentioned, except by the geographers. In A.D. 360 it became associated with the name of Julian the Apostate, who fortified the Ile de la Cité, and built on the mainland the Thermæ Juliani (a palace with baths, of which the extensive remains are still in excellent preservation), besides other edifices on both sides of the river. At this time, or even earlier, Lutetia was a bishop's see. According to one account, St Denis, the patron saint of France, suffered martyrdom at Paris about the middle of the third century. To the Romans succeeded the Franks, who, under Clovis, seized Paris in 494. Most of this monarch's successors fixed their abode there, and, having embraced Christianity, founded many churches and abbeys, and otherwise enlarged and embellished the town. Under the Merovingians, Paris rose to considerable importance, being regarded by the Salian or Neustrian Franks as the capital of their dominions. In 574 it was burned to the ground in a war waged by Sigebert, King of Metz, against his brother Chilperic, King of Soissons. By the princes of the Carlovingian line Paris was neglected, and its fortifications allowed to fall into decay. On this account, when it was attacked by the Northmen in 841, it fell an easy prey. Fifteen years later, the Normans again appeared before the ruined walls, and burnt some of the churches, holding the rest to ransom. In 861 a third invasion of these northern pirates, attended with the same results as before, showed the necessity of putting the town in a state of defence. This was done by Charles le Chauve, and so effectually, that when the Normans assaulted the city for the fourth time in 885, they were completely foiled, and only escaped destruction by concluding with Charles le Gros a treaty which cost that monarch his crown. The vacant throne was then offered to Count Eudes or Otho, in whose family it became hereditary in the person of Hugo or Hugues Capet in 987. This monarch chose Paris for his residence; and from that time the city became the capital of the kingdom of France. In the reign of Louis VI. (Le Gros), the Louvre was rebuilt, the Palais de Justice was commenced, and the fortresses of Le Grand and Le Petit Chatelet were constructed to command the bridges that joined the Cité with the mainland. The fame of Paris as a seat of learning began to spread, and many new streets were erected for the students who flocked thither in crowds. Ten men sufficed, however, to collect all the taxes; and the duties levied at the North Gate produced under Louis VI. only 12 francs a year, or about 600 francs of present money. A wall was thrown round these extended suburbs by Louis VII., whose successor, Philippe Auguste, enlarged the limits of the city by inclosing a wide sweep of ground with a new *mur d'enceinte*. The space thus inclosed was in course of time

covered with the churches and other religious establishments erected by St Louis between the years 1226 and 1270. Of these the only one that has survived is the Sainte Chapelle, now restored in more than its original splendour. In the reign of St Louis the bourgeoisie of Paris were confirmed in many important privileges, in return for the help which they afforded to the king against his rebellious barons. There was no recognised municipality in Paris at this time; but the guilds of merchants and traders, which had existed since the times of the Romans, were amalgamated by St Louis into a sort of municipality, sometimes called the *marchandise* or *hanse Parisienne*, whose chief, under the title of *prévôt des marchands*, exercised a wholesome judicial authority. One of his functions was to administer, in concert with the *prévôt de Paris*, the police of the city, which till this time had been very defective. In 1250 the Sorbonne was founded; and soon afterwards a hospital for the blind, a school of surgery, and a body of notaries were instituted. Under the successors of Louis the progress of the city was seen in the foundation of numerous colleges, abbeys, and churches, and the growing spirit of independence among the towns-people. In 1306 the citizens for the first time rose in arms against the king. They rebelled against the heavy taxation to which they were subjected by Philippe IV. (Le Bel). After a temporary success, the mutineers were quelled, and twenty-eight of the ringleaders were hanged. Philippe, however, found it convenient for the future to fill his coffers by means more popular than the taxation of his own subjects. Accordingly, Paris saw with scarcely a murmur the Jewish residents among them banished and robbed of all their property, and in the following year (1307) the cruel extirpation of the Knights Templars. In this reign, however, the streets and highways were improved, and some courts of law were established. During the absence of King John as a captive in England the peace of Paris was embroiled by the faction of the Maillotins under Etienne Marcel, prévôt des marchands, instigated by Charles le Mauvais, King of Navarre. Marcel, however, was slain by his own partizans; and the Dauphin, afterwards Charles V., quelled the mutiny. The faubourgs had meanwhile been considerably extended beyond the *mur d'enceinte;* and as they were threatened from time to time with attacks by the English, new walls and ditches, which it took sixteen years to complete, were drawn round them in 1367. Under Charles V., the Bastille and the Palais des Tournelles were built, and the Louvre enlarged and repaired. Charles V. was succeeded in 1380 by Charles VI., in whose reign the bridges of St Michel and Nôtre Dame were built in 1384 and 1414 respectively. In 1420, by the treaty of Troyes, Paris passed into the hands of the English. An unsuccessful attempt was made in 1429 by Joan of Arc to retake the city. A second attack, conducted by Dunois and the Count de Richemond, in 1436, had a different issue. The English garrison was surprised and put to the sword. A few men only, who took refuge in the Bastille, were allowed to escape with their lives. Under Charles and some of his immediate successors, Paris was desolated by war, pestilence, and famine, to such a degree that at one time it was seriously intended to transfer the seat of government to some healthier and safer city on the Loire. Such was the insecurity of life, that in the environs, and occasionally in the streets of the capital itself, numbers of people were destroyed by the wolves. So rapidly, however, did it recover from its disasters, that by the time of Louis XI., who came to the throne in 1461, the population was upwards of 200,000, and the city and the surrounding country were in such a flourishing condition that, in the words of Comines, "C'est la cité que jamais je visse entourée de meilleurs pays et plantureux, et est chose presque incrédible que des biens qui y arrivent." Louis XI. had an especial favour for Paris, and used to say, "Ma bonne ville de Paris, si je la perdais, tout serait fini pour moi." He encouraged trade and commerce to the utmost of his power, and set up in the Sorbonne the first printing-press that was established in France. Though neglected by the immediate successors of Louis, Paris continued to grow and prosper, and added to its old monuments some new ones of great importance, such as the Fontaine des Innocents, the Hôtel de Cluny, the churches of St Merry and St Eustache, and the College of France. Francis I. restored the fortifications and enlarged the circuit of the city, besides adorning it with some handsome public buildings. The old castle of the Louvre was demolished, and a new and splendid palace, which still remains, was erected on its site. The Faubourg St Germain, which had been destroyed in the wars, was restored, and the foundations of the Hôtel de Ville were laid. In 1563 the chateau and garden of the Tuilleries were formed by Catherine de Medici, and the enceinte enlarged so as to comprise them within its circuit. Paris was at this time regularly divided into sixteen quarters, and its administration was conducted by—1*st*, The *Prévôt de Paris*, appointed by the King, and having under him two lieutenants, one civil and the other criminal, who presided in the court of the Chatelet, with its twenty-four members; 2*d*, The *Prévôt des Marchands*, chosen by the trades, and assisted by thirty-two assessors; 3*d*, The *Garde Bourgeoise;* and 4th, The *Guet Royal*, consisting of 500 foot soldiers and three companies of archers or musketeers. These tribunals exercised their functions with great and often undiscriminating severity, yet were sometimes unable to make head against the bands of thieves, vagabonds, and beggars, who, to the number of fourteen or fifteen thousand, frequently combined to plunder and disturb the town. It was not till the time of Louis XIV. that the arm of the law was strong enough to put down these ruffians completely. In the religious wars of the sixteenth century, Paris suffered severely. The events that followed the massacre of St Bartholomew in 1588, the formation of the League, the *journée des barricades*, and the sieges sustained by the city from Henri III. and his successor Henri IV., destroyed great numbers of the inhabitants, and the streets and houses in which they dwelt. When the edict of Nantes restored peace to France, Henry had leisure to carry out his plans for embellishing the capital. The Pont Neuf, begun in the previous reign, was completed; the Hôpital St Louis was founded; the Place Royale, the Rue Dauphine, and some fine quais along the river, were laid out; the building of the Tuilleries, and of the galleries connecting that palace with the Louvre, was vigorously prosecuted; and the two westernmost of the islands in the Seine were united to that of La Cité. Under Louis XIII. many splendid structures were added to the city. The Palais Cardinal, now the Palais Royal, was begun by Richelieu, who also founded the Académie; the Luxembourg was commenced by Marie de Medici; the Jardin des Plantes was laid out by Labrosse, one of the royal physicians; the enceinte of the city was extended almost to the line of the present boulevards; the quais and bridges of the Ile St Louis were constructed; the Pont au Change was rebuilt; and a wooden bridge, now replaced by the Pont Royal, connected the quarter of the Louvre with the Faubourg St Germain, where many splendid hotels now began to rise. The police, though now a little better administered than of old, was still so badly administered that crimes and vices of the most hideous kind might be indulged in with impunity. During the supremacy of Mazarin, Paris was harassed by the never-ceasing outbreaks of the Frondeurs; and insurrections, barricades, and street-fighting recurred periodically. The distress occasioned by these feuds was such, that on one occasion in 1653 it was estimated that of the entire population of the city, then amounting to about 400,000 souls,

one-tenth was without any ostensible means of livelihood. As soon as he attained his majority, Louis XIV. began to carry out the plans of his father and grandfather. Eighty new streets were laid out, and many of the old ones repaired and embellished. Thirty-three new churches, besides chapels, were erected; while the Hôpital Général, or La Salpêtrière, afforded shelter to the homeless poor, and the Hôtel des Invalides to old or disabled soldiers and seamen. The observatory, the colonnade of the Louvre, and the Pont Royal were completed; and the Champs Elysées were planted. The palace of the Tuilleries was finished; and its gardens were laid out nearly as they now stand. The Place Vendôme and the Place des Victoires were formed; and the triumphal arches of St Denis and St Martin substituted in room of two of the old city gates. The ancient fortifications of the northern part of the city were demolished, and their site converted into a splendid succession of promenades. The streets were now for the first time lighted at night; the police was greatly improved, and the drainage and sewerage of the town received special attention. In 1710 the population of Paris amounted to 490,000 souls. Under Louis XV. the progress of the city was neither so rapid nor so great as under his predecessor. Some of the splendid streets in the faubourgs St Honoré and St Germain were opened in his reign; the Palais Bourbon, now the seat of the Legislative Assembly, the Panthéon, or church of St Geneviève, the Mint, and the École Militaire were founded; the Place de la Concorde was laid out; and the porcelain manufactory at Sèvres established. The peace of the city was during this reign never broken by such feuds as had troubled it in past ages. Some slight tumults resulted from the general distress that followed the bursting of the Mississippi bubble, and the other financial schemes of Law, but they were easily suppressed. Louis XVI. continued the Pantheon and began the Madeleine, and other less important churches. The Français, the French, Italian, and comic opera-houses, and some minor theatres, rose in rapid succession. Many new fountains were opened, and the water of the Seine was distributed through various parts of the city by means of steam-engines erected on its banks; the enciente of the capital was again extended, and some villages, such as Chaillot, Roule, and Monceaux, formerly beyond the walls, were now incorporated with the city. The Palais Royal, diverted from its original use, was parcelled out into shops, and the gardens inclosed in its quadrangle were thrown open as places of public recreation. The population of Paris at this time, according to Necker, amounted to about 620,000. The reign of Louis XVI. was inaugurated with bread riots, forecasting the more terrible events that were speedily to follow. The history of Paris during the Revolution becomes a history of the Revolution itself, all the leading events and ideas of which originated in the capital. On the 14th July 1789 the Bastille was taken and destroyed. The sufferings of the people from famine during the ensuing months led to almost daily riots, in which many lives were lost. In the October of this year the king, then living at Versailles, was brought in triumph to Paris by the mob, and the National Assembly likewise transferred its seat to the capital. Order was not restored till martial law had been proclaimed; but despite the utmost exertions of the authorities, *émeutes* were constantly taking place during the next two years. On the 20th June 1792 the mob rose and attacked the Tuilleries, where the royal family was then residing; on the 10th August of the same year the attack was repeated, and the Swiss bodyguards of the king were slain to a man: Louis himself was deposed and confined a prisoner in the Temple. On the 2d of September 1792 the mob rose, broke open the prisons, and murdered all the inmates, to the number of about 5000. The National Convention supplanted the Assembly, and the doctrines of the Mountain became rampant. On the 21st of January 1793 Louis was executed on the guillotine which had been set up in the Place Louis XV., or, as it is now called, de la Concorde; and when the "Reign of Terror" was inaugurated, on the overthrow of the Girondist party in the Convention, and the supremacy of the Clubs, executions took place daily to the number of fifty or sixty, sometimes even of a hundred. After a time, the guillotine was removed from the Place Louis XV. to that of the Bastille, and thence to the Place du Trône, where it remained till brought back to its original site for the decapitation of Robespierre and the leading terrorists. Before the Convention gave place to the Directory, it had introduced some important reforms,—abolished the commune of Paris; silenced the Clubs, or reduced them to order; and organized the Bureau des Longitudes, the Polytechnic School, and the Institute of France. The Directory maintained itself in power from 1795 till the revolution of the 18th Brumaire (8th November 1799) left Napoleon virtually master of France. In the course of twelve years, as first consul and emperor, the new ruler of France expended upwards of four millions sterling on the extension and embellishment of the capital. Three new bridges were built over the Seine; three great cemeteries were formed beyond the walls, and five abattoirs constructed; many new fountains and markets were opened in different parts of the city; the quais were extended along the banks of the river; and a number of new and handsome streets were begun. The churches destroyed during the Revolution were restored, many of them in more than their former beauty. On the abdication of Napoleon in 1814, Paris fell into the hands of the allies after a gallant defence by the garrison, the National Guard, and the students of the Polytechnic and Veterinary Schools. The events that followed Waterloo and the final deposition of the emperor again gave up Paris into the hands of the stranger, but on neither of these occasions was much damage done to the city. The Prussians had made arrangements for blowing up the Pont de Jéna, but were prevented from carrying out their design by the firmness of the Duke of Wellington. Louis XVIII. entered Paris on the 8th of July 1815, and the old Bourbon line was reinstated on the throne of France. He carried out many of his predecessors' plans; built three new bridges and three churches, and greatly improved the lighting and cleansing of the metropolis. During his reign Paris enjoyed almost undisturbed tranquillity. The only *émeute* that occurred took place in 1827, on the occasion of an election of deputies to the Chamber. Barricades were erected, but the troops proved faithful to the king, and the insurrection was put down with little loss of life. Subsequent attempts to renew it proved equally abortive. Charles X. was less lucky or less prudent than his brother. On the 27th of July 1830 he published the famous ordinances, suppressing the charter of 1814, annulling elections, and abolishing the liberty of the press. Instantly the Parisian people were up in arms. Four thousand barricades were raised; the Swiss guards, and the gendarmerie under Marshal Marmont, fought desperately for a time, but failed to make head against the mob. The troops lost about 400 men in killed and wounded; the insurgents 783 slain, and 4500 put *hors de combat*. In honour of these patriots, a monumental column, with their names inscribed in letters of gold, was erected in the centre of the Place de la Bastille. Their bodies were deposited in vaults beneath the column, which was completed and solemnly inaugurated on the 28th July 1840. The Orleans branch of the family succeeded to the throne in the person of Louis Philippe. The new sovereign was fortunate enough to escape all the repeated attempts to assassinate him, and lived to complete numerous works of great beauty and importance. Among those which he finished may be men-

tioned the churches of the Madeleine, St Vincent de Paul, Nôtre Dame de Lorette, and St Denis; the Hôtel de Ville, and the triumphal Arc de l'Etoile. The Place de la Concorde was remodelled, and adorned with splendid statues and fountains, and an interesting obelisk of great size brought from Luxor in Upper Egypt. Some of the old quais were widened, and new ones were built and planted with trees. Gas was introduced into the town, and vast works were undertaken for the drainage of the streets. The greatest and most costly, however, of all the public works were the fortifications of Paris. The whole of the city and its faubourgs were surrounded with a fosse and a high rampart, commanded along their whole line by fourteen detached forts, some of them of great size and strength. The cost of these works exceeded twenty millions sterling. Till the year 1848, Louis Philippe's reign secured peace and prosperity to Paris and to France. Some of his later acts, however, rendered him very unpopular; and when, in 1848, he obstinately opposed the movement for electoral reform, the mob rose, and the army eventually sided with the people. Louis Philippe abdicated in favour of his grandson, the Count of Paris; but it was too late. A democratic republic was proclaimed, and a constituent assembly convoked to draw up the constitution. The extreme party, the Red Republicans as they were called, disgusted with what seemed to them the too conservative spirit of the new government, began to embroil the public peace by their violent teaching of the wildest doctrines of socialism. Clubs were formed which, by the 15th of May, became strong enough to seize the Hôtel de Ville and establish a provisional government of their own. The leaders of the movement were arrested and thrown into prison; but new leaders appeared; and on the 23d of June the civil war broke out. The eastern half of Paris was in the hands of the insurgents, who threw up barricades in all the great thoroughfares, some of them exceedingly strong and scientific in their construction. For three days—the 24th, 25th, and 26th of June—a bloody combat was fought, and with doubtful issue, till the arrival of the artillery decided the action in favour of the government forces under General Cavaignac, who had been nominated dictator by the Assembly. The lives lost during the insurrection amounted to at least 15,000, and the sums paid by the city to compensate for the destruction of property amounted to L.223,945 sterling. In the canvass for the presidency of the new republic, Louis Napoleon Bonaparte proved the successful candidate. During his term of office no outbreak occurred; but Paris and France were agitated by the intrigues of all the parties and factions that had lately believed themselves entitled to a share in the administration. Towards the close of 1851 an attempt was made in the Chambers to encroach on the powers of the president, who had made himself highly popular with the army and the mass of the peasantry. Accordingly, on the 2d December Louis Napoleon declared Paris in a state of siege, dissolved the Legislative Assembly, and restored universal suffrage. He then appealed to the people, offering himself as candidate for a ten years' presidency. He was appointed by a majority of about seven millions and a half of affirmative votes. On the anniversary of the *coup d'étât*, which had been effected with much less bloodshed than usually attends such changes of government in France, he was promoted, or promoted himself, to the higher dignity of emperor of the French, under the title of Napoleon III. The public works that mark his reign far surpass in number and splendour all the achievements of his predecessors. The Louvre has been completed on a style of almost unparalleled grandeur, and joined to the Tuilleries; the Rue de Rivoli has been prolonged to the Hôtel de Ville; many new streets, some of them hardly inferior to it in point of splendour, have been opened up; the tomb of Napoleon I., in the Hôtel des Invalides, has been finished, and the Ste. Chapelle restored; a railway has been formed, encircling the city, and connecting all the lines that issue from it; the Champs Elysées and the Bois de Boulogne have been splendidly embellished. Other works are either contemplated or are already in progress, which, when carried out, will have remodelled to a great extent the entire aspect of the city.

The circumference of Paris is now 25,978 yards, or upwards of $14\frac{1}{2}$ miles. Its area at different times is shown in the subjoined table:—

Under Julius Cæsar	B.C.	56	37 acres.
„ Philippe Auguste	A.D	1211	625 „
„ Charles VI.	„	1383	1084 „
„ Henri III.	„	1581	1193 „
„ Louis XIII.	„	1634	1403 „
„ Louis XIV.	„	1686	2728 „
„ Louis XV.	„	1717	2809 „
„ Louis Philippe	„	1848	8708 „

The last official measurement gives the area of the city as 35,240,000 square mètres, equal to 42,150,640 square yards, or 8710 acres.

The plain in which Paris stands is about 60 mètres above the level of the sea, and is surrounded in its entire circumference by a range of low hills. The heights inclosing the northern and more considerable part of the town skirt the shore of the Marne above its junction with the Seine, sink between Rosny and Montreuil, rise again in the plateau of Belleville, disappear altogether in the plain of St Denis, attain in the hill of Monmartre, one of their most elevated points, an altitude of 295 feet above the river, cross the plain of the Batignolles, and terminate in the slopes of Passy and Chaillot. The southern, like the northern portion of the city, is pretty nearly semicircular. The hills that screen the southern portion of the city are less high than those which inclose the northern. Almost level at the eastern extremity of Paris, the ground rises with a gentle slope into the plateau of Ivry and the hill of Cailles, where it is intersected by the Bièvre. Passing that little stream, the first eminence to be seen is the Mont Ste. Geneviève, behind which extends the plateau of Montrouge, from the western end of which rise the slight elevations commanding the barriers of Maine and Mont Parnasse. Between Vaugirard and the river lies the level plain of Grenelle. Beyond these rising grounds, and at a distance of from 3 to 5 miles S. and W. of the city is a ridge of hills with several points of considerable height. Of these may be mentioned, Villejuif, Meudon, St Cloud, and Mont Valérien. The inner range of hills, encircling the southern part of the city, furnished the stone from which much of Paris was built. These old quarries are now built over, the excavations serving as catacombs, into which, when the intramural cemeteries were cleared in 1786, the bones of at least three millions of persons were thrown. The Seine enters the city at Bercy, and leaves it at Passy, the distance between these points by the river-course being nearly five English miles. About half-way the river flows round the two islands of St Louis and La Cité, the three other islets which formerly existed at this spot being now incorporated with one or other of these, or with the mainland. From Bercy to Passy there is an unbroken line of quais on both sides of the stream. The breadth of the Seine at the Pont d'Austerlitz is about 182 yards; at the Pont Neuf, 288 yards; and at the Pont de Jéna, 149 yards. The mean velocity of the water is 20 inches a second. In summer it is sometimes so low as to be fordable; in winter it rises high, has a very rapid current, and sometimes does great damage by overflowing its banks. Numerous barges, laden with firewood, coals, &c., unload at the wharves; and small steamboats for the local traffic, and occasionally a sea-going vessel or two, are to be seen plying on the Seine. No impurities are allowed to pollute its waters, the sewerage of the city being otherwise disposed of. Floating wash-houses, and

bathing and swimming schools, stud the surface in great numbers. The river communicates with the Loire by the canals of Briare and Orleans, with the Somme and Scheldt by the canal of St Quentin, and with the Saône by that of Bourgogne.

It was long a favourite scheme of the French kings to fortify the capital; and in 1841 a grant of 140 millions of francs was voted to Louis Philippe for the purpose. The fortifications, as they now stand, consist of two parts,—1*st*, A continuous enceinte, bastioned and terraced with 10 mètres revetment; and, 2*d*, Seventeen detached forts, besides occasional detached trenches. The ditch has an average depth of 20 feet, and a breadth of from 60 to 165 feet. The crest of the parapet is 14 mètres above the bottom of the ditch. Military roads connect all the forts with Paris and with each other. The enceinte embraces within its sweep the whole of the capital and its faubourgs. The seventeen detached forts are,—Fort Charenton, Nogent, Rosny, Noisy, Romainville, d'Aubervilliers, De l'Est, Couronne du Nord, Fort de la Briche, Fort du Mont Valérien (with strong bomb-proof casemates and large barracks), Fort de Vanvres, D'Issy, Montrouge, Bicêtre, Ivry, Lunette de Stains, and Fort de Rouvray. The inner wall of Paris is quite unconnected with the defence of the city. It is pierced by fifty-six gates or barrières, at which the octroi, or local dues on taxable articles entering the capital are levied. Of these barriers, the handsomest are those of Neuilly, Du Trône, St Martin, Fontainebleau, Chartres, and Passy. A series of broad roads, planted with fine rows of trees, runs round the outside of this wall, and forms the external boulevards. The wall itself, begun in 1787, but not completed till the time of Napoleon I., comprises the majority of those quarters or suburbs which, from lying beyond what was at the time the city proper, are called faubourgs. Of the faubourgs embraced within the octroi wall, the chief are, on the north side of the river, those of St Honoré and the Roûle on the N.W.; Chaussée d'Antin, Montmartre, Poissonnière, St Denis, and St Martin on the N.; the Temple on the N.E.; and St Antoine on the E. On the other side of the river are those of St Victor on the S.E.; St Marcel, St Jacques, and St Michel on the S.; St Germain and Gros Caillou on the S.W. Beyond the sweep of the octroi wall are the faubourgs of Auteuil, Passy, the Batignolles, La Villette, Belleville, Ménilmontant, Charonne, Bercy, Montrouge, Vaugirard and Grenelle.

Paris is bisected by the Seine. In the northern, which is the newest and most important part of the city, the streets run for the most part either parallel with the river or at right angles to it. The great arteries are the quais, the Rue St Honoré, and the Boulevards. In the Cité no plan seems to have been observed in laying out the streets and houses. But the changes of the last ten years have swept away or greatly altered the Cité of the middle ages, which had survived till that time. The houses, as in every part of Paris, were built of stone, and were generally from five to eight storeys in height. The streets were so narrow that a person walking in the middle of them, with arms outstretched, could in many cases touch the houses on either side at once. At night they were either not lighted at all, or were illuminated by the dingy *réverbères*, which, during the revolutions, were so often used as a gallows. Most of these old streets have in late years been pulled down. Wherever practicable, foot pavements have been laid, gas introduced, and the gutter transferred from the centre to the sides of the streets. Similar improvements have been effected, where required, in the streets of less ancient date on both sides of the river. The lighting of Paris is now effected by 1595 oil and 14,000 gas lamps, fed by 1,464,236 feet of pipes, and supplying nearly 560,000 cubic feet of gas. During six months all the lamps are lighted every night; and during the remainder of the year a certain number for part of the night. The northern boulevards, occupying the site of the fortifications demolished by Louis XIV., are now planted on both sides of the way with rows of trees, and constitute the most brilliant part of the city, from the size and elegance of the houses and the splendour of the shops and restaurants, which adorn them in a continuous line from the Madeleine to the Place de la Bastille. The stone used in building the houses is the marine limestone (*calcaire grossier*), found abundantly in the Paris basin; and as the inhabitants are bound by law to scrape, paint, or whitewash their houses once every two years, the general aspect of the city is always clean and gay. The sweeping of the streets costs the city a million and a half of francs yearly, and is effected by 2500 scavengers of either sex. More than L.120,000 sterling are annually spent in repairing the streets and pavements; and during the last fifty-five years more than L.8,000,000 sterling have been spent in widening them.

Except the Place de la Concorde, none of the "places," or public squares of Paris, are memorable for their size, though several of them are remarkable for their beauty. The Place de la Concorde connects the garden of the Tuilleries with the Champs Elysées. The centre of it is believed to furnish the finest *coup d'œil* in Europe. Looking towards the east, the eye falls first on the palace of the Tuilleries, facing which, at a distance of about three-fourths of a mile, stands the noble Arc de Triomphe de l'Etoile; another vista discloses the magnificent church of the Madeleine, confronted by the hall of the Chamber of Deputies. The "Place" itself is splendidly decorated. Eight thrones, supporting eight figures, representing the principal cities of France, besides numerous groups of statuary, encircle it. In the centre stands the famous obelisk of Luxor, marking the site of the guillotine during the first revolution. Two of the largest and finest fountains in the world play during the greater part of each day. The most noteworthy of the other places are the Place des Victoires, with its fine statue of Louis XIV., the Place Royale, the Place du Trône, and the Place Vendôme. In the last-named of these stands the Colonne Vendôme, erected by Napoleon to commemorate his victories in the German campaign of 1805. The pillar is an imitation of Trajan's Column at Rome, and is 135 feet high, with a diameter of 12 feet. The bas-reliefs of the shaft, cast out of 1200 pieces of Austrian and Russian cannon, comprise 2000 figures, in a spiral scroll 840 feet long. The pillar is now surmounted by a bronze statue of the first Napoleon, 11 feet high. The total cost of it was L.60,000 sterling.

The public buildings of Paris are so numerous and so interesting that to dwell upon or even enumerate all that deserve, and in fact require notice, is impossible. Perhaps the most important in the history of Paris, especially during the last seventy years, is the palace of the Tuilleries, the official residence of the reigning monarch. It takes its name from the tile-fields on the site of which it stands, and was founded by Catherine de Medici in 1564. It was enlarged by Henri IV., and again by Louis XIII., who left it externally very much in the condition in which it now stands. The façade is 330 yards in length, and 36 in breadth. The columns of the lower storey of the central façade are Ionic; those of the second, Corinthian; of the third, composite. Though not a beautiful building, its size and its peculiar lofty roof and chimneys, are very impressive. The internal decorations are in a style of splendour which it is difficult for any who has not seen to conceive. Both the galleries connecting the Tuilleries with the Louvre are now complete; that on the south is nearly 1500 feet in length, and contains a magnificent collection of paintings of the French, Dutch, German, and Italian schools. The Louvre itself, once a royal residence, is now used as a repository for the art treasures of the National

Museum, and contains vast and well-arranged collections of Greek, Roman, Egyptian, and Assyrian antiquities; many masterpieces of the leading painters and sculptors of most ages and countries; and a museum, in which are preserved models of the most important arsenals, ships, and forts, and everything, in short, connected with the maritime defences of the country. It consists of two parts—the old Louvre, designed by Claude Perrault, and the new Louvre, by Visconti. The old Louvre is nearly a square, 576 feet in length by 538 in breadth, and inclosing a quadrangle of 394 feet square. Its eastern façade, looking towards the church of St Germain l'Auxerrois, is a colonnade of twenty-eight coupled Corinthian columns, and is justly reckoned one of the finest pieces of architecture of any age. The new Louvre consists of two vast lateral piles of buildings, projecting at right angles from the two parallel galleries which join the old Louvre with the Tuilleries, and forming the eastern boundary of the Place du Carrousel. Turning into the Place Napoleon III., they present on each side a frontage of 590 feet, intersected by three sumptuous pavilions. These vast structures are intended to accommodate the minister of state, the minister of the interior, and the library of the Louvre. Some of the galleries on the upper storeys are to be set apart for permanent and annual exhibitions of the works of living artists. The Tuilleries and the Louvre, both now completed and harmonized, may be regarded as forming together a single palace, of a magnitude and splendour to which a parallel can nowhere be shown. The total space covered or inclosed by the entire structure amounts to nearly 60 English acres. The money expended on the new works already exceeds a million and three-quarters sterling; and large additional sums will be required for the decorations that remain to be introduced.

The Palais du Luxembourg, now the Palais du Sénat, in the southern portion of the city, was built in 1612 for Marie de Medici, on the model of the Pitti Palace in Florence. It is a handsome edifice, consisting of a centre and two wings, connected by terraced arcades. At the revolution of 1789 it was converted into a prison, and afterwards was called successively Palais du Directorie, Palais du Consulat, and Palais du Sénat. At the restoration it became the Chambre des Paires, and since 1852 for the second time Palais du Sénat. A fine collection of the masterpieces of modern artists adorns one of the galleries of the Luxembourg. The gardens attached to the palace are extensive and beautiful. A broad avenue of great length leads from the Luxembourg to the Observatory. A bronze statue, erected in 1854, marks the exact spot in this avenue where Marshal Ney was shot on the 7th December 1815. The Hôtel des Invalides also, on the southern side of the Seine, was founded by Louis XIV., in 1670, for old or disabled soldiers and sailors. Additions have been made to it from time to time, till it now covers 16 acres of ground, inclosing 15 courts, and is capable of accommodating 5000 inmates. The ordinary number of inhabitants is between 3000 and 4000. Attached to the hotel is the church, with its beautiful double dome, 173 feet high, surmounted by a graceful lantern-globe and cross. The height to the top of this cross is 323 feet. Under the dome is the tomb of the Emperor Napoleon I. This, the most superb mausoleum in the world, was designed by Visconti, and cost from first to last about L.360,000 sterling. A little further down the river is the Champs de Mars, oblong in form, and 2952 feet long by 1476 broad. It was in this plain that the Fête de la Fédération was held on the 14th July 1790. Here, too, Napoleon held the famous Champ de Mai before the battle of Waterloo. The Champ de Mars is now used for reviews and races. At its southern extremity stands the École Militaire, now a barrack.

At the southern end of the bridge connecting the Place de la Concorde with the Faubourg St Germain stands the Palace of the Legislative Body, formerly the Chamber of Deputies, the façade of which, built in 1804, consisting of twelve Corinthian columns that rest on a broad flight of twenty-nine steps, and support a triangular pediment, measuring 95 feet at the base and 17 feet high, is much admired. A little way up the river stands the Palais du Quai d'Orsay, a magnificent structure begun by Napoleon I., but not completed till the time of Louis Philippe. It was designed as a palace for the exhibition of the products of French industry, but is now used by the Council of State. Separated from the Palais d'Orsay by an intervening street, is the Palais de la Légion d'Honneur, also a fine building, though externally somewhat insignificant. Still higher up the river, and on the quai opposite the Louvre, stands the Palais de l'Institut, occupying the site of a college founded by Cardinal Mazarin, and containing two valuable libraries—the Bibliothèque Mazarine, with 150,000 printed books and 3700 MSS.; and the Bibliothèque de l'Institut, with about 100,000 printed books. The latter library is especially rich in scientific books, both French and foreign, and possesses the transactions and periodicals of almost every scientific association in the world. East from the Palais de l'Institut, and close beside it, is the Hôtel des Monnaies, or Mint. The façade of this edifice fronting the Quai Conti is 360 feet long, with an elevation of 76 feet; that towards the Rue Guénégaud is 348 feet in length. The Mint is far from handsome externally, but is interesting for its extensive and admirably arranged collection of coins and medals. The coining-machines, eleven in number, are singularly ingenious in their structure, and when worked all at once, produce coin to the value of a million and a half sterling a day. Still further east, on the opposite bank of the river, stands the Hôtel de Ville, the residence of the Prefect of the Seine, and the meeting-place of the municipality of Paris. This handsome edifice was founded in 1533, but not completed till many years later. During the revolution of 1789 it suffered great damage. In 1837 it was restored and extended to about four times its previous size. As it now stands, it is a rectangle, with a handsome pavilion at each angle, and two more in the eastern and western facades, the latter of which, as the principal façade of the building, is adorned besides with an elegant belfry over the great central doorway. The reception-rooms of the Hôtel de Ville are decorated with a taste and brilliancy unsurpassed in any even of the imperial residences of France. They form a circuit of about half a mile, and require for their complete illumination 9714 tapers and 2389 gas-burners. They can accommodate 7000 visitors at once without discomfort.

The ecclesiastical edifices of Paris are, in magnitude and splendour, worthy of the general palatial aspect of the city. Conspicuous among them in point of architectural beauty, as well as of historic interest, is the cathedral of Nôtre Dame on the Ile de la Cité. This superb temple was begun about the year 1000, and completed in 1312, and exemplifies the Gothic architecture of the intervening centuries in its noblest form. It is a regular cruciform, with an octagonal eastern end. The western façade is flanked by two lofty square towers, intended for spires, which, however, have never been built. The interior consists of a nave and choir, with double aisles and lateral chapels between the outer buttresses. The building is 390 feet in length, 144 feet wide at the transepts, and 102 feet from the floor to the vaulting of the roof. The towers are 204 feet high, and the western front is 128 feet in length. The nave is 255 feet long by 39 broad; the roof, made of chesnut timber, is 356 feet in length, and rises 30 feet above the internal vaulting. The chapels are adorned with many impressive pictures; and the sculptures, both external and internal, are quaint and striking. Totally different

in kind, but equally splendid with Nôtre Dame, is the church of the Madeleine, at the extreme western end of the northern boulevards. It was begun in 1764. The works were slowly progressing, when, after the Prussian campaign, Napoleon determined to convert it into a Temple of Glory to commemorate the exploits of his armies. His abdication frustrated this design; and in 1815 Louis XVIII. restored it to its original destination. It was completed in the reign of Louis Philippe at a total cost of L.523,160 sterling. The Madeleine is the finest reproduction in modern times of any ancient model. Its archetype was the Parthenon at Athens, which, however, it greatly surpasses in size. The Parthenon was only 228 feet long by 100 broad. The Madeleine stands on an elevated platform 418 feet in length, and is 328 feet long by 138 broad. It is reached by a flight of 28 steps, and is surrounded by a colonnade of 52 Corinthian columns, 15 on each side; 14 on the southern portico, and 8 in the northern. The entablature, ceiling, and pediment of the colonnade are lavishly adorned with sculpture. The decorations of the interior are very splendid, but their effect is better suited for an opera-house or a picture gallery than a Christian temple. In a totally different style of architecture is the Panthéon, which, a few days after the *coup d'étât* of 1851, Louis Napoleon restored to ecclesiastical uses and to its original name of the church of Ste. Géneviève. The Panthéon is cruciform, and from the centre of the cross springs a lofty circular drum surrounded by a peristyle of 32 Corinthian columns. Above rises a splendid dome, the highest point of which is 268 feet above the pavement. The portico is composed of 22 fluted Corinthian columns 60 feet high, supporting a pediment 120 feet long and 24 in height. The sculpture in the pediment, by David, represents the genius of France surrounded by the great men of the nation. On the frieze beneath is inscribed in gold letters—"Aux grands hommes la Patrie reconnaissante." The total length of the building, including the portico, is 352 feet; interior length from east to west, 295; length of the transept, 265 feet; uniform breadth, 104 feet. The remains of Voltaire and Rousseau were removed to the Panthéon in 1791, but were secretly taken away during the Restoration. Among the illustrious dead buried in the vaults are Lagrange the mathematician, Bougainville the navigator, the Dutch Admiral de Winter, Soufflot the architect of the church, and Marshal Lannes. Mirabeau and Marat were also interred here, but their remains were afterwards removed. The Panthéon was begun in 1764 by Louis XV. and afterwards restored by Louis XVIII. It has cost in all about a million and a quarter sterling. Close to the Panthéon is the church of St Etienne du Mont, with a very beautiful interior. Of the other Parisian churches, the handsomest are St Sulpice near the Luxembourg, the two towers of which are used as telegraphic stations; St Vincent de Paul, in the N.E. corner of Paris, one of the finest churches in the city; St Eustache, lately restored with great splendour; and St Roch, both noted for their musical services; Nôtre Dame de Lorette; St Germain des Près; and St Germain l'Auxerrois, opposite the eastern front of the old Louvre, interesting for its curious frescoed portico, and as the church from the belfry of which the signal was given for the massacre of St Bartholomew, August 23, 1572.

The hospitals and benevolent institutions of Paris are very numerous. The hospitals are of two kinds—general and special; and besides these there are hospices, analogous to the English alms-houses. The total number of beds in these establishments is at present 17,469. The oldest and most important of the hospitals is the Hôtel Dieu, on the Ile de la Cité, close to Nôtre Dame. It is known to have been in existence in the twelfth century, and was subsequently much enlarged in the reigns of Henri IV. and Louis XVI. At present it contains 850 beds, and gives relief to about 12,000 patients annually. The mortality is 1 in 18. The next in importance are the hôpitals Lariboisière, de la Pitié, de la Charité, Beaujon, St Antoine, Necker, and Cochin. Of the hospices, the most important are those des Ménages, des Enfants Trouvés, des Orphelins, des Incurables, and the Bicêtre. The civil hospitals are managed by the Administration of Public Assistance; the military, three in number, are under the control of the staff of the garrison of Paris. The incomes of the civil hospitals are derived from legacies and donations, from the tax of 10 per cent. of the sums received at theatres and other places of amusement, a tax on cemeteries, a portion of the octrois of the city of Paris, and of the profits of the Mont de Piété. In 1856 the number of patients treated in the hospitals amounted to 94,774; of those treated at their own homes, 32,584. Relief in money was given to 40,474 sick persons, and in kind to 172,842. In that same year the revenue of the hospitals and hospices amounted to L.625,133, and the expenditure to L.662,463. The average of the mortality in the general hospitals was 1 in 10·82, and in the special 1 in 13·25; in the hospices, 1 in 7·99. Two hospitals have lately been founded by Napoleon III. for workmen disabled at the great public works. Besides the hospices and hospitals, there is a vast number of charities, both lay and clerical. There are also 13 asylums and houses of retreat for the blind and for deaf-mutes. Crêches or public nurseries are established in different parts of Paris. Poor women who work in factories or out of doors deposit their children in the crêche as they go to their work in the morning, return to feed them at certain hours of the day, and carry them home at night. There are 18 such institutions in Paris.

Of the public commercial establishments of Paris, the handsomest is the Bourse, begun in 1808, and completed in 1826, at a cost of L.325,960 sterling. It is a parallelogram of 212 feet by 126, surrounded by a peristyle of 66 Corinthian columns, the effect of which is exceedingly graceful. The Banque de France is a very plain building; (for its administration and history see article MONEY, section x.) The Halle au Blé, or corn-market, is a vast circular building, begun in 1763, and finished in 1767. The Halle aux Vins is an immense inclosure on the S. bank of the Seine, with an area of 31,100 square yards. The warehouses and vaults have room for 400,000 casks. The other wholesale markets are the Halle aux Draps and the Halle au Cuir. The Mont de Piété was created in 1777 for the benefit of the hospitals, and has the exclusive right of lending money on moveable effects, at the rate of 9 per cent. a year. There are 45 branches of the establishment in France. In 1857 the number of pledges was 3,400,087, representing a value of L.1,956,890. The savings-bank (Casse d'Epargne et de Prévoyance), was founded in 1818. In 1855 the number of depositors amounted to 228,985, the receipts to L.981,595, and the payments to L.934,036.

There are 24 retail markets in Paris, and the number of the merchants who trade in them is about 9000. The finest are the Marché St Germain, the Marché des Innocents, with its beautiful fountain, and the new markets beside the church of St Eustache. The excellent abattoirs of Paris are 5 in number, and were finished in 1818 at an expense of L.660,720. Three of them are on the N. side of the river, those, namely, of Montmartre, Popincourt, and the Roule; on the southern side are those of Villejuif and Grenelle. The first two have 64 slaughter-houses each; that of Grenelle 48; the other two, each 32.

The population of Paris was estimated in 1798, at 640,000; in 1802, at 672,000; in 1806 it was 580,609; in 1817, 713,966; in 1827, 890,431; in 1836, 909,126; in 1846, 945,721; in 1856, 1,174,346. In 1856, the date of the last census, the number of births for that year was

37,697, of which 19,110 were male, and 18,587 female; 25,948 were legitimate, and 11,749 illegitimate. Of the latter class, 2522 were legitimized after birth. The number of marriages that took place in 1856 was 12,493; in 10,177 of which neither party had been previously married; in 1268 the male, and in 597 the female; and in 461 both had been previously married. The total number of deaths was 29,950, of which 14,755 were males, and 15,195 females; 11,072 died in the various hospitals, 152 in the prisons, 361 were deposited in the morgue, and one was executed. Of the males, 9522 were unmarried, 3772 married, and 1150 widowers; of the females, 8672 were unmarried, 3737 married, and 2736 widows.

The ordinary revenue of Paris for 1858, derived from the octroi, the markets, abattoirs, ground-rents, &c. amounted to L.2,781,537; the extraordinary to L.65,000; making a total of L.2,846,537. The ordinary expenditure for the same year amounted to L.1,675,902; the extraordinary to L.1,208,484; making a total of L.2,884,386. The largest item in the expenditure is for the interest of the municipal debt, L.656,268; the next largest is for the prefecture of police, L.516,645. The municipal debt amounted in 1855 to L.5,137,719.

The details of the principal articles of consumption in Paris, as furnished by the last official returns (for 1856) are as follows:—Wine, 22,986,828 gallons; brandy, spirits, and liquors, 1,675,511 gallons; cider, 421,180 gallons; vinegar, 500,000 gallons; beer, 6,396,305 gallons; olive oil, 140,229 gallons; other kinds of oil, 2,546,025 gallons. The weight in pounds of the food consumed during the same year was as follows:—Beef and mutton, 151,943,094; veal, 4,023,774; pork, 20,688,447; hams and sausages, 2,940,702; charcuterie, 2,182,832; suet, 4,306,576; salt, 15,228,064; cheese, 3,974,804; poultry, game, rabbits, &c., 2,633,685; butter, 6,926,262; eggs, 3,787,243; fish of all kinds, 161,236; grapes, 7,745,526. The total value of these articles is estimated at about L.14,000,000 sterling. The wine represents a value of about L.2,000,000 sterling; milk, rather more than L.750,000; groceries, upwards of L.3,000,000; bread, L.1,520,000; meat, L.1,600,000; vegetables, about L.600,000. The number of bakers, as fixed by law, is 601; of butchers, 500; of restaurateurs, 1720; and of wine and spirit dealers, 3182.

The trade of Paris is very extensive. In the variety and importance of its productions it is surpassed by few cities in the world. The special exports of the city were valued in 1837 at L.3,760,000; in 1847, at L.6,742,887; in 1848 (a year of revolutions), at L.6,120,000; in 1851, at L.8,800,000; and in 1852, at L.8,860,000. The average, calculated on the last sixteen years, gives a yearly value of L.4,640,888. The number of trades in the city is 325, carried on by 65,000 masters, 205,000 workmen, 112,800 women, 16,600 boys, and 7700 girls. The trades connected with dress produce nearly 10 millions sterling a-year; those with food about 9 millions; those with building about 6 millions; furniture about 5½ millions; jewellery about 4 millions; bronze about a million; basket-making, &c., nearly as much; hats three-quarters of a million; and gloves more than half a million. The looms engaged in the shawl trade are 752 in number; the manufactories of haberdashery are 999; there are 879 millinery shops, 225 ready-made clothes shops, 653 stay-makers, 644 hatters, 1915 cabinetmakers, 222 carvers, 519 upholsterers, 141 paper-stainers, 120 mirror-makers, and 450 decorators.

The history and statistics of the university of Paris are given in the articles FRANCE and UNIVERSITIES. The students attending the various faculties number about 6500. Of the schools and lycées, the most important are,—The Collége Impérial de France, with a staff of 28 professors; the Musée Impérial d'Histoire Naturelle, with 17 professors; the Conservatoire des Arts et Métiers, for the technical education of artizans, with 14 professors; the École Normale, with 18 professors and 80 students; the Lycée Louis-le-Grand, with 42 professors, 370 boarders, and 500 day scholars; the Lycée Napoleon, 18 professors and 350 boarders; the Lycée St Louis, 45 professors, 340 boarders, and 500 day scholars; the Lycée Charlemagne, 40 professors and 800 day scholars; the Lycée Bonaparte, 33 professors and 1100 day scholars; the Collége Stanislas, with 10 professors and 200 boarders; and the Collége Ste. Barbe, with 80 professors and 1000 boarders and day pupils. Besides these, there are special schools, for the most part belonging to government. The principal of these are the three military schools,—the École Polytechnique, with 300 pupils; the École des Ponts et Chaussées, with 15 professors and 100 students; and the École de l'Étât Major: the École des Mines, for the study of geology, mining, &c.; the École des Chartes, for the study of the ancient manuscripts in the various public libraries of France; the Ecole des Beaux Arts, for painting and sculpture, and architecture, with 20 professors; the Conservatoire de Musique, with 10 bursaries of L.40 each, and 600 pupils. The three colléges municipaux of Rollin, Chaptal, and Turgot, belonging to the city of Paris, give a good commercial education at a very moderate cost. The private "institutions" and "pensions" are under government control. There are 50 institutions, and 240 pensions for boys; and 180 institutions, and 123 pensions for girls. There are 22 adult schools, attended by 2700 pupils. Of the écoles primaires, there are, for boys, 33 écoles mutuelles, and 30 écoles simultanées; for girls, 35 of the former class, and 32 of the latter. The écoles mutuelles have 13,700 pupils of both sexes; the écoles simultanées, 15,600. The expense of these primary schools to the municipality is about L.54,800 annually.

The prisons of Paris are eight in number,—the Prison Modèle or Nouvelle Force, a model prison with accommodation for 1260 inmates, and costing annually about L.4000; the Maison d'Arrét des Madelonnettes, with about 600 inmates, and costing annually about L.1500; the Dépôt de la Prefecture de Police, a place of temporary confinement, where accused persons are kept for twenty-four hours, after which they are either liberated or removed to some of the other jails; the Conciergerie in the Palais de Justice, in which prisoners are kept during their trial; the debtors' prison, holding 300 to 400 inmates, and costing about L.1200 a year; Ste. Pélagie, with an average population of about 550 persons, and costing about L.1600 annually; St Lazare, with an average population of from 900 to 1100, and costing about L.3000 annually; the Dépôt des Condamnés, with an average of 400 inmates, and an annual cost of L.1400; and the Maison Centrale d'Education Correctionnelle, or Prison des Jeunes Détenus, with an average of 500 inmates, and an annual cost of L.1280.

The number of theatres in Paris is at present twenty-three, with about 34,000 seats, and a nightly average of about 20,000 spectators. The principal theatres, such as the Italian Opera, the Français, and the Opera-Comique, besides others, are subsidized by government. The Grand or French Opera is now managed by government altogether. The secondary theatres are the Odéon, the Théatre Lyrique, the Vaudeville, Gymnase, Variétés, Porte St Martin, &c. There is also an equestrian circus in the Champs Elysées, besides two hippodromes, one at the east and the other at the west end of the city, capable of accommodating each about 10,000 spectators. The annual receipts of these places of amusement average now about half a million sterling, 10 per cent. of which is claimed by government for the maintenance of the hospitals and charitable institutions. The public gardens, concerts, and balls, which are very numerous, are frequented by crowds of pleasure-seekers both in summer and winter

Paris is the seat of the imperial government of the executive and legislative authorities, of the Cour de Cassation (supreme court of appeal), and of an archbishop whose suffragans are the bishops of Meaux, Versailles, Chartres, Orléans, and Blois. It is the head-quarters of the first military division which comprises the departments of Seine, Seine-et-Oise, Oise, Seine-et-Marne, Aube, Yonne, Loiret, and Eure-et-Loire. For municipal purposes it is divided into twelve arrondissements, each of which is subdivided into four quarters. Each arrondissement has a separate municipality, presided over by a mayor and two deputy-mayors. The prefect of the Seine is the chief municipal authority of the capital. Under him is a council of prefecture, composed of five members and a secretary-general, with a municipal and departmental commission consisting of 36 members. The members of this commission are also members of the council-general of the department, which comprises eight additional members for the arrondissements of Sceaux and St Denis. (Galignani's *Paris Guide;* Malte-Brun; Balbi; Theophile Lavallée's *Histoire de Paris;* MacCulloch's *Geographical Dictionary*; *Annuaire de l'Economie Politique;* &c. (J. C—L.)

PARIS, surnamed *Alexander*, was the second son of Priam and Hecuba, the King and Queen of Troy. His birth was attended by the most singular circumstances. Immediately before he was born, his mother dreamed that she brought forth a torch, which set fire to the whole city. This dream was interpreted to mean that the coming infant would bring destruction upon Troy. Accordingly, no sooner had the child come into the world than his terrified parents, devoting him to death, exposed him on the neighbouring mountain of Ida. There he was suckled by a she-bear, until, at the end of five days, a shepherd found him, took him home, and adopted him. As the youthful Paris grew up, his princely endowments, shining forth from under his humble peasant-garb, began to exercise their legitimate influence. His graceful and refined comeliness won the heart of Œnone, the beautiful daughter of a river-god. He became the champion of the shepherds in their conflicts with the wild beasts of the forest, and was honoured with the surname of Alexander, "the defender of men." The fame of his exquisite taste and accomplishments even reached the ears of the immortals, and procured for him a notable honour. A golden apple, bearing the inscription "for the fairest," was brought to him from the gods; he was commanded to award it; and Juno, Minerva, and Venus presented themselves before him in the vale of Ida as the claimants. Besides dazzling his eyes with the uncovered brilliancy of their celestial charms, the goddesses tempted his judgment with bribes. Juno promised him a kingdom, Minerva military glory, and Venus the fairest woman in the world. The last offer won the partiality of the susceptible judge, and he awarded the prize to the goddess of love.

This decision led Paris into a course of action which brought ruin upon his native country. Having been discovered and recognised to be the son of Priam, he was placed in a position in which he resolved to avail himself of the promise which Venus had given to him. Hearing, therefore, of the surpassing beauty of Helen, the wife of Menelaus, King of Sparta, he fitted out a fleet, repaired to her husband's court under the guise of friendship, carried her off, and brought her home to his father's palace. The Greek chieftains soon arrived at the head of their forces to exact the restoration of the seduced queen; and thus the Trojan war, which ended in the destruction of Troy, was begun. During this famous struggle Paris did not show his usual valour. It is true that he twice advanced to meet his injured foe Menelaus; but on the first occasion he fled ignominiously before the Spartan hero, and on the second he would have been slain had not Venus interposed to save him. It is also true that he slew Mnesthius, and wounded Diomede and other Greek heroes; but he was fonder of passing the day in idle dalliance than of fighting before the walls of the city. The death of Paris is said to have been caused by one of the arrows of Hercules shot from the bow of Philoctetes. Apollo is reported to have assumed his form in order to slay Achilles.

PARIS, *Matthew*, one of the earliest of English chroniclers, flourished in the thirteenth century, and is supposed (as his surname seems to imply) to have been born or educated in the capital of France. Although a poor Benedictine monk in the monastery of St Albans, he appears to have attained to note in public life. Henry III. held him in great favour and esteem; and the Pope employed him on a mission of reformation to the monasteries of Norway. Still higher was his position as a man of varied acquirements. He was well versed in history, theology, and the general learning of his age; and he was adorned with the accomplishments of an architect, a painter, an orator, and a poet. But it was in the character of a historian that his greatest fame was achieved. Indefatigable in his search after the fullest historical accounts, he embodied in a condensed form all the substance of former chroniclers, and was careful to add all the possible information regarding his own time. His principal work, entitled *Historia Major*, consists of an emended copy of Roger of Wendover's *Flowers of History*, carrying the narrative as far as 1235, and a supplement continuing the story down to 1273. It was first printed by Archbishop Parker in 1571, and it has been frequently reprinted both in London and Paris. An English translation, by the Rev. J. A. Giles, forms 3 vols. of Bohn's *Antiquarian Library*.

To his chief work Matthew Paris wrote an abridgment, entitled *Historia Minor*, and a supplement containing *Lives of the Two Offas, Kings of Mercia, and of Twenty-three Abbots of St Albans*, and *Additamenta*. The former exists only in manuscript, the latter is printed in the edition of the *Historia Magna* by Dr William Watts, fol., London, 1640.

PARIS, *John Ayrton*, an eminent physician, was born at Cambridge in 1785. His educational career was marked by uncommon devotion to learning. At an age as early as fourteen he began the study of medicine under Dr Bradley of London. Entering Caius College in his native town in 1803, he made himself familiar with the classics, and dipped into chemistry and botany. Then he studied medicine at Edinburgh, and took his degree of M.D. at Cambridge, with so much credit, that in his twenty-third year he was appointed physician to the Westminster Hospital. After staying for a short time in London, Dr Paris settled at Penzance in Cornwall; and there a new field of study was opened up before his active mind. The physical character of the county induced him to devote his leisure hours to the pursuits of the geologist. He published several papers on geology, wrote a geological *Guide to Mount's Bay and Land's End*, and founded the Royal Geological Society of Cornwall, one of the earliest societies of the kind in the kingdom. He also invented the "tamping-bar," an iron implement covered with copper, which miners can use without incurring the danger of striking fire from the rock, and igniting gunpowder or inflammable gas. In 1810 Dr Paris, returning to London, entered upon a long career of professional and scientific industry. His duties as a physician were performed with all the cheerful ardour of one who loves his calling for its own sake. At the same time, he laboured with the pen to promote medical science. His *Pharmacologia*, his *Treatise on Diet*, his *Elements of Medical Chemistry*, and his *Elements of Medical Jurisprudence*, written in conjunction with Fonblanque, were all produced amid the hurry of numerous engagements. The great eminence of Dr Paris was recognised with the high-

est honours. He was a D.C.L. of Oxford, and a fellow of the Royal Society and other learned societies in London. He was also president of the London College of Physicians, a position which he held from 1844 till his death in December 1856. Dr Paris was the author of an anonymous work entitled *Philosophy in Sport made Science in Earnest*, and of an excellent biography of his friend Sir Humphry Davy.

PARISH, the precinct of a parochial church, or a circuit of ground inhabited by people who belong to one church, and are under the particular charge of its minister. The word comes from the Latin *parochia*, and the Greek παροικια, *habitation*, compounded of παρα, *near*, and οἰκος, *house*. Accordingly, Du Cange observes, that the name παροικια was anciently applied to the whole territory of a bishop, because the primitive Christians, not daring to assemble openly in cities, were forced to meet secretly in the neighbouring houses. In the ancient church there was one large edifice in each city for the people to meet in, and this they called *parochia*, or parish. But the signification of the word was afterwards enlarged, and by a parish was meant a diocese, or the extent of the jurisdiction of a bishop, consisting of several churches; unless we suppose, as some do, that those bishops were only pastors of single churches. Dupin observes, that country parishes were unknown before the fourth century; but those of cities are more ancient. The city of Alexandria is said to have been the first which was divided into parishes. Of the first division of parishes there is no certain information; for in the early ages of Christianity in this island, parishes were unknown, or at least signified the same thing as diocese. There was then no appropriation of ecclesiastical dues to any particular church; but every man was at liberty to contribute his tithes to any priest or church that he pleased; or if he made no special appropriation of them, they were paid to the bishop, whose duty it was to distribute them amongst the clergy, and for other pious purposes, according to his own discretion. Camden says (*Britannia*, p. 160) that England was divided into parishes by Archbishop Honorius about the year 630. Sir Henry Hobart maintains that parishes were first erected by the council of Lateran, held in the year 1179. But Selden (*History of Tithes*, chap. ix.) proves that the clergy lived in common, without any division of parishes, long after the time mentioned by Camden; and it appears from the Saxon law that parishes were in being long before the Council of Lateran in 1179. The distinction of parishes first occurs in the laws of Edgar about the year 970. It seems pretty certain, says Justice Blackstone (*Com.*, vol. i., p. 112), that the boundaries of parishes were first ascertained by those of a manor or manors; because it very seldom happens that a manor extends itself over more than one parish, although there are often many manors in one parish. As Christianity spread, the lords began to build churches upon their own demesnes or wastes, in order to accommodate their tenants in one or two adjoining lordships; and, that they might have divine service regularly performed therein, they obliged all their tenants to appropriate their tithes to the maintenance of the one officiating minister, instead of leaving them at liberty to distribute them amongst the clergy of the diocese in general. The tract of land, the tithes of which were thus appropriated, formed a distinct parish; a circumstance which accounts for the frequent intermixture of parishes one with another. For if a lord had a parcel of land detached from the main part of his estate, but not sufficient to form a parish of itself, it was natural for him to endow his newly-erected church with the tithes of such lands. Since 1818 important improvements have taken place in the parochial divisions of England through the appointment of "The Ecclesiastical Commissioners." (See Stephen's *Comm.*, vol. iii., p. 102, &c.)

PARISH-CLERK, a person in every parish whose duty it is to assist the parson in the rites and ceremonies of the church. Parish-clerks were formerly clerks in orders, and their business at first was to officiate at the altar, for which they had a competent maintenance by offerings; but they are now generally laymen, and have certain fees at christenings, marriages, and burials, besides wages for their maintenance. The parish-clerk is generally appointed by the incumbent, but by custom may be chosen by the inhabitants. By the common law, parish-clerks have freeholds in their offices, but may (by statute 7 and 8 Vict., c. 59) be suspended by the archdeacon for misconduct or neglect.

PARK, MUNGO, a celebrated traveller, was born at Fowlshiels, near Selkirk, on the 10th of September 1771. His father occupied the farm of Fowlshiels under the Duke of Buccleuch. He appears to have bestowed uncommon attention on the education of his children; and he even employed a tutor to reside in his house, an expense which was then supposed to exceed the resources of an ordinary farmer. Young Park made a good figure at school. His general demeanour was reserved and thoughtful; yet occasional sparks of ambition broke forth, indicative of that adventurous spirit which lay concealed under a somewhat cold exterior. This thoughtful disposition led his friends to consider the church as the profession best suited to his character; but as he himself preferred physic to theology, his wishes were acquiesced in; and he spent three years at the university of Edinburgh in the studies necessary to qualify him for that profession.

At Edinburgh, Park studied with ardour and success; and in particular he imbibed a fondness for botany, which served to give a strong colour to his future life. It strengthened his natural connection with his brother-in-law, Mr James Dickson, who, notwithstanding many disadvantages, attained such skill in that science, that, on going as a gardener to Hammersmith, he obtained a large share of the patronage and favour of Sir Joseph Banks. This connection induced Mr Park to repair to London. He was introduced to Sir Joseph, who was so much pleased with him that he obtained for him the appointment of assistant-surgeon to the Worcester East Indiaman. In this capacity Mr Park performed a voyage to Bencoolen, where he made some collections and observations in botany and natural history, which were submitted to the Linnæan Society, and an account of them printed in the third volume of their Transactions.

The African Association were now anxiously looking out for a successor to Major Houghton, their unfortunate missionary, who had perished in the attempt to penetrate to the Niger and Timbuctoo. This opening, although foreign to any of Mr Park's former pursuits except that of natural history, was immediately embraced by him with an ardour which showed how congenial it was to the character of his mind. Without hesitation, he offered himself for this arduous and perilous service, and, being supported by the recommendation of Sir Joseph Banks, he was at once accepted.

Park spent about two years in and near London, acquiring the qualifications necessary for his mission. In May 1795 he set sail; and on the 21st of June following arrived at Jillifree, near the mouth of the Gambia. After spending some months with Dr Laidley at Pisania in acquiring the Mandingo language, he, on the 2d of December 1795, departed on his grand expedition. By what route he reached the river, how much of its country he explored, and by what track he returned, is described under NIGER. He arrived, after the length of his absence and the want of intelligence respecting him had nearly extinguished all hopes of his safety. Reaching London early in the morning of Christmas 1797, he went to pass the time before breakfast in the gardens of the British Museum, where, by

a singular chance he met Mr Dickson, who embraced his friend as one returned from the grave. An extraordinary interest in his adventures was immediately excited amongst the African Institution, its friends, and the public in general. Major Rennell drew up an important memoir, showing the new light thrown by his journey upon African geography, which, with an abstract of his narrative by Mr Bryan Edwards, was speedily offered, to satisfy the curiosity of the public. In the spring of 1799 Mr Park presented the public with a full narrative from his own pen. Major Rennell's memoir was appended, and a considerable part of Mr Edwards' abstract was incorporated verbatim; upon which circumstance alone seems to have been built the rumour of that gentleman having been the actual writer of the volume. The work was read with an avidity proportioned to the novelty and importance of the information contained in it, and to the interesting and agreeable manner in which the events were narrated.

Having finished this task, Mr Park seems to have resolved to retire into domestic and professional life. In 1799 he married Miss Anderson of Selkirk, daughter of the gentleman with whom he had served his apprenticeship as a surgeon. In October 1801 he embraced a professional career at Peebles, and soon found himself in respectable practice. He now seemed sufficiently comfortable, being happy in domestic life, possessed of a competence, and surrounded by respectable society; yet his active mind was secretly panting after a higher sphere of exertion.

Important as were his discoveries, their effect had been, not to satisfy, but to excite still farther, the public curiosity. The course of the Niger through the unknown and central parts of the continent could not fail to excite peculiar interest. This was strongly felt, not only by the scientific world, but by some intelligent members of administration, who, on the conclusion of the peace in 1801, determined to fit out an expedition on a great scale, to effect the discovery of the termination of this great river. In autumn 1803, Lord Hobart, afterwards Earl of Buckinghamshire, who was then colonial secretary, offered the command of it to Mr Park, who, though he asked a short interval to consult his friends, seems never in his own mind to have hesitated as to its acceptance. To those who represented to him the dangers that were to be incurred, he urged, that the hardships attendant on the exercise of his profession, his journeys to distant patients, his long and solitary rides over "cold and lonely heaths," and over "gloomy hills, assailed by the wintry tempest," would tend as effectually to shorten life as the journey now in contemplation.

Accordingly he set sail from Portsmouth on the 30th January 1805. The melancholy history of this second expedition is well known. With what equipments he departed from Pisania on the 4th May 1805, how his forty-four European companions dwindled down to four, and how he was at last drowned at Boussa, is related under NIGER.[1]

Park has been pronounced by some the first of modern travellers. Without altogether adopting this opinion, we may observe, that the problem of the course of the Niger, which he had the fortune partially to solve, was one which had involved in error almost all former geographical systems on Africa. D'Anville, indeed, had stated it correctly; but as he had not communicated the grounds upon which his conclusion rested, the opposite opinion, which represented the Niger as flowing westward, and joining the ocean by the channel of the Senegal, continued still prevalent. This point, finally decided, fixed the geographical character of the continent. In Bambarra, also, a name as yet scarcely heard of by Europeans, Park found a kingdom much farther advanced in civilization than had yet been supposed to exist in the heart of Africa.

Mr Park's literary, though not equal to his active qualifications, were nevertheless respectable. But notwithstanding his knowledge of botany, he cannot be considered as a scientific traveller. We see not in him that varied and splendid science which, in Humboldt, illustrates and adorns, though it sometimes overlays, the main subject. But with regard to the general aspect of nature, and the forms of human society, his observations are careful, accurate, and judicious. Nothing can be more lively than the idea which we receive from him of the African forests and deserts, the cities of Bambarra, the stream of the Niger or Joliba, and the regions watered by that river. The spirit, joined to the simplicity of his narrative, has rendered his work one of the most popular of its kind in the English language.

Mr Park's bodily frame was well fitted for the arduous enterprises in which he engaged. He was six feet in height, his limbs were well proportioned, and his whole frame was active and robust. His countenance was prepossessing, and his manners always retained their native plainness and simplicity. But this was combined with a natural coldness and reserve, which rendered his conversation less interesting than was expected by those who considered his general talents and extensive opportunities of observation. His conduct in all the relations of private life was highly exemplary. He left a widow, three sons, and a daughter. (H. M.)

PARKER, MATTHEW, the second Protestant Archbishop of Canterbury, was born at Norwich in 1504, and entered the university of Cambridge in 1520 as a student of Corpus Christi College. His studies were prosecuted with distinction. In 1523 he took a bachelor's degree; in 1527 he was ordained, created a Master of Arts, and chosen a fellow; and by this time he had become so eminent for his theological attainments that he received an offer, which was not, however, accepted, of a chair in Wolsey's newly-founded college at Oxford. This successful career as a scholar was followed by a still more successful career as a priest. Having received a preaching license from Archbishop Cranmer in 1533, he was often appointed to preach at court. In a short time his learning, piety, and attachment to the Reforming party in the Church, recommended him to the favour of the royal family; and a succession of preferments was the result. Anne Boleyn made him her chaplain in 1534; Henry VIII. appointed him one of the king's chaplains in 1537; and Edward VI. presented him to the deanery of Lincoln in 1552. He was also receiving at the same time several other dignities and rich benefices. During the reign of Mary, Parker was deprived of all his honours and preferments, and was obliged to seek safety in obscurity. Scarcely grieving at the misfortune which allowed him to enjoy literary leisure and domestic intercourse, he lived in the houses of his Norfolk friends, and devoted his attention to the translation of the book of Psalms into English. Occasionally the emissaries of the bloody queen would track him to his studious retreats, and force him to flee. He continued to shift about from one place to another until the accession of Elizabeth in 1559 restored him to favour and influence. Parker was then nominated archbishop of Canterbury; and the duty of building up the Protestant church of England out of the ruins of Popery was entrusted to him. This great task he performed with rare assiduity, courage, and magnanimity. He

[1] The narrative of this journey was published in 1815 in 4to, with a very interesting biographical memoir and preface by Mr Wishaw. It may not be amiss to notice here a singular oversight in Park's Journal observed by M. Walckenaer. A 31st day is counted in April (p. 7); and as all the days before and after are accounted for, there can be no doubt that all the following dates are one day behind. This, as Mr Bowdich has shown, is not so trifling an error as at first sight it appears; for a false declination being thus taken, an error, greater or less, and sometimes not inconsiderable, is committed in the calculation of all the subsequent latitudes.

Parliament

dared to discountenance that lingering attachment to the relics of Popery which was manifested by the queen herself. His influence was constantly exerted to supply the vacant cures with men of orthodoxy, learning, and piety. Although no bigoted devotee of mere ecclesiastical formalities, he strove to preserve the unity of the church by enjoining an uniformity in habits and ceremonies. He also promoted the growth of vital religion among the community by his daily exercise of deep piety, public-spirited zeal, and active Christian benevolence. Nor did the liberal-minded primate fail to advance the cause of religion still further by advancing the cause of general enlightenment. A munificent patron of learning, he founded several schools, and presented several of the colleges at Cambridge with scholarships, fellowships, and with large bequests of plate, money, books, and manuscripts. A zealous lover also of learning, he prosecuted antiquarian and kindred studies with great success. The edition of the Scriptures called *The Bishops' Bible*, and the treatise *De Antiquitate Britannicæ Ecclesiæ*, were produced under his superintendence; and he printed the four old English historians—Matthew of Westminster, Matthew Paris, Asser, and Thomas Walsingham. The death of Archbishop Parker took place in 1575. (Strype's *Life and Acts of Matthew Parker*, in 3 vols., Oxford, 1821; and *Biographia Britannica*.)

Parkgate || Parliament

PARKGATE, a small town of Cheshire, on the right bank of the estuary of the Dee, 10 miles N. by W. of Chester. It is neatly and regularly built, and is much frequented for sea-bathing. The harbour is obstructed by a sand-bank; but it is a station for packets sailing to Ireland. A fine view of the coast of Flintshire may be obtained from the town.

PARKHURST, John, a learned lexicographer, was born at Catesby in Northamptonshire in 1728, and attended the school of Rugby. Having become a student of Clare Hall, Cambridge, he took the degree of M.A., was elected a fellow of his college, and entered into holy orders. A handsome competence which he inherited enabled him to devote all his time to literary pursuits. Accordingly, till his death in 1797, he assiduously applied himself, in spite of a weak constitution, to biblical studies. His principal works, a *Hebrew and English Lexicon, without Points*, and a *Greek and English Lexicon to the New Testament*, became very popular, and have been often reprinted. The latest edition of the former was published in 1845, that of the latter in 1851.

PARLIAMENT.

Parliament is the name of the supreme legislature of Great Britain. The immediate derivation of the word is disputed, but that it has a common etymological source with the French *parler*, to speak, cannot be doubted. The term is not confined to Britain. It long designated in France a set of institutions which performed some administrative functions, but were properly the chief provincial courts of justice. The body, which for some time in France was the parallel of the English Parliament, and appeared to be marching on to the same high destinies, was called the States-General, or the three estates. These had many formidable contests with the Crown before they were suppressed, or rather dropped out of the rank of French national institutions. Their last ordinary meeting was in 1614, under Louis XIII., and much interest subsequently bore on the proceedings of that assemblage, as they formed the latest precedents for the guidance of that memorable re-assemblage of the states-general, which ushered in the dawn of the great Revolution. The Cortès of Spain were a parliament powerful and free, and at one time also promising a noble rivalry with that of England. In other countries the institution has been more or less developed, but the true object will best be served by adhering entirely, under the article Parliament, to an account of the supreme legislature of the United Kingdom, the most illustrious development of representative government, and the model on which all other sound constitutions must necessarily be framed in spirit if not in detail, as being the great storehouse of legislative wisdom, in which all that has been ever devised by political philosophy, has been put to the test of practical application. This notice will therefore be confined, after a rapid history of its rise in the three kingdoms, to a statement of the existing constitution and practice of the Parliament of the United Kingdom.

History of the Parliament of England.

It has hitherto been an idle task to endeavour to prove that Parliament belongs either to "the institutions of our Saxon ancestors," or the feudal system. In its present state, it is as much the creation of a high social development, and perfected political science, as the railway and the electric telegraph are the developments of mechanical and chemical science. Whatever glimpses we have of the early progress of the institution, must be considered as the efforts of a practical people, making use of such established institutions as fell to their lot, towards the perfection of a free and strong system of representative government. It is far safer, in tracing the history of this progress, to take such palpable facts as occur from time to time, showing stages in the development, than to rely on theoretic views. It may perhaps be true, that the spirit of the institutions of our Saxon ancestors influenced the subsequent progress of Parliament, but very little satisfaction has come out of any attempts to show that the Saxons possessed an institution practically resembling our Parliament. The practices which are among the earliest, and are among the present characteristics of Parliament, cannot be traced into the Saxon period; because we cannot find there the royal summoning, the hereditary principle, and the representative principle; while the institution of slavery, which made a large portion of the community not only the inferiors, but the absolute property of the other, was antagonistic to the spirit of feudal gradation, which gave to the great lords individual power as legislators, and to the smaller people collective power as the choosers of representatives.

We know that the earliest Norman kings not only acted on the advice and consent of certain persons eminently powerful among their subjects, but stated the concurrence of such persons in the official promulgations of the royal will, as giving it strength and validity from their constitutional authority. Antiquaries have been much puzzled to identify the common or general council consulted by these early kings; but there is no doubt that there has been much confusion about the meaning of the word *concilium* or *consilium*, as employed in old documents; and thus it has been supposed to indicate a council or body of persons, when it meant in reality the advice or counsel given by those persons whether assembled or not. (See Municipal Corporation.) Sometimes, too, the act of a sovereign, or even so important a thing as the succession of a sovereign, does not profess to be merely sanctioned by the advice or by the consent of any limited assemblage of persons, however important, but bears to be by the assent or choice of the whole community; and, as in modern times, the universality of the assent or choice was often the more strongly asserted the farther it was from the truth. Whatever were the qualifications of the advisers who surrounded the early Norman kings, they must have been expected to be numerous,

since Westminster Hall was built by Rufus for their reception. Their duties were as much judicial and administrative as they were legislative. The supreme courts, the privy council, and other institutions, by degrees branched off from this great council, carrying with them the judicial and ministerial functions; and the appellate jurisdiction of the House of Lords, along with the general etiquette that all members of that House are among the sovereign's councillors, remain to us as relics of the judicial and ministerial functions of these early Parliaments. The term Parliament was first used towards them in the reign of Henry III. In the mean time traces are found of an important distinction. Whatever was the rank of the persons attending the Parliament or great council, they were all tenants-in-chief of the king,—all immediately attached to him, and not under any mediate superior in the feudal hierarchy. In the charter of King John a difference was made according to their rank in the method of requiring their attendance. The great barons were to be individually required to attend by special writ addressed to each; the other tenants-in-chief, not called barons, were called by a general summons—seeming to imply, that such of them as thought fit, or were delegated by their brethren, might attend. It is here that we have the germ of a House of Lords, consisting of men who are legislators by individual right, and of a House of Commons, consisting of chosen respresentatives. The marks of another significant distinction may be found in these early vestiges. The charters then so frequently issued were bargains by the monarch; among other things, assuring his subjects, that he would not take from them talliages or taxes, save such as were due. The promise not to take did not involve a promise not to ask; and the chief early function of Parliaments was to receive royal appeals for money. Now, by the great barons or tenants of royal demesnes, considerable taxes were due to the Crown by feudal law, and did not require to be asked; and we find the monarch taking his dues from them, and craving more from those tenants of knights' fees, or portions of them, who had enriched themselves with other kinds of property, and who possessed wealth, which, unlike that of the tenants of the great demesnes of the Crown, was not legally taxable. When we find these consenting to share in the burden, we have the foreshadowing of a Lower House asserting and jealously maintaining the exclusive right of dealing with all matters of supply. Another peculiar mark of distinction tends in the same direction. The ecclesiastical lords, the bishops and abbots, sat, like the first temporal lords, as the tenants of baronies or estates; and it is said that the bishops are still a living relic of this primitive system of enoblement. Like the other great barons, these ecclesiastics were liable to pay feudal dues and taxes without being specially asked for an aid. When the king, however, wished an aid from the clergy at large, irrespective of their baronies, they granted it sitting in a separate assembly or convocation of their own.

Originally, as is well known, the tenure of a baronial fief from the king made a baron or lord of Parliament. Whoever legally possessed that estate, was, in virtue of it, a lord of Parliament without any separate title. In the course of time, however, the monarch began to create higher dignities of his own special grant. The dukedom, taken from the practice of the Roman empire; the marquisate, or margravate, copied from a later institution of the empire, which appointed great lordships, partaking of the nature of monarchies, on the marches for the protection of the empire; the earldom, a revival of an old Saxon title; and the viscounty. The mere barons by tenure not unwillingly accepted of these dignities, which naturally overshadowed, and at length superseded, the humbler barony by tenure. The title of baron fell at last to be conferred in the same manner by royal writ or patent; and the peers of England came to be virtually peers by writ and not by tenure. The question, whether the old enobling by tenure still exists, though latent, has curiously enough just reappeared, as we shall presently see.

With regard to the Commons, the earliest summons of a limited number of the lesser freeholders has been assigned to the year 1213, when King John, citing his barons, required the sheriffs at the same time to cause to come to the king at Oxford four discreet knights from each shire to talk with him about the affairs of his kingdom.[1] To see, however, how the representative system was brought out, we must turn to another and not a naturally obvious source.

The municipalities which arose throughout England became part of the feudal hierarchy—they were chief tenants of the Crown. (See MUNICIPAL CORPORATION.) However its position in the hierarchy might be theoretically adjusted, there was no possibility of calling the community of a city, like an individual baron, to attend the king's court. But in the old Roman constitution of the municipality there was a remedy for the difficulty. Although a community, it had a head,—a representative of its several members for the management of its internal affairs. The idea had to be but slightly extended, and the same, or another, selected head might represent the municipality in the king's Parliament. There can be no more emphatic reproach to those who insist on founding our parliamentary system solely on Saxon, or solely on feudal usages, than thus to find that it took one of the most valuable of all hints for its development from that Roman law which was professedly so much detested in England. It is well known, that the municipalities or burghs were first called to Parliament by the renowned Simon de Montfort in 1264; and there can be little doubt that the very apt method of representation which they found to their hand immediately reduced to symmetry the vague and undefined arrangements by which a few of the freeholders appeared for themselves and their brethren in the Lower House. How Parliament from this time onward grew in strength and efficiency is matter of history, and will in some measure be explained when the functions of Parliament are treated of in this article. The juncture at which the principle was established that the assent of the two Houses is necessary to every legislative act, has been assigned by Hallam and others to the reign of Edward IV. It was very soon afterwards that they asserted the right to inquire concerning grievances, and demand their redress. The feebleness of the Crown has ever been the opportunity of Parliament. During the reign of Richard II., England, as well as Europe at large, was swept by a revolutionary outbreak of the oppressed serfs of the soil, who, in France, rendered themselves ever memorable as the *Jacquerie.* In England there was an intermediate body, powerful to keep order, but at the same time not negligent of the opportunity for augmenting its own strength; and while the cause of order and the law triumphed over Tyler's rebellion, a part of the power for their enforcement was found to have changed hands from the king to the Parliament. In this reign the Commons achieved the important function, in addition to the granting of the supplies, of assigning them to their destined uses. Soon afterwards, but not without a stubborn resistance, they accomplished a material change in the order of business. They used to present their

[1] In this and the immediately preceding statements, the best general reference that can be made is to the somewhat voluminous *Reports from the Lords' Committees appointed to search the Journals of the House, Rolls of Parliament, and other Records and Documents, for all matters touching the dignity of a Peer of the Realm,*—an enormous mine of information on matters connected with the early history of Parliament.

Parliament of England

grievances, then grant their supply and receive the redress of the grievances—not always satisfactory—at the end of the session. They now insisted that the redress should be obtained before the supply was granted. In this, and in other instances, the disputes between the English monarchs and their Parliaments, exhibit in their bald outline the one party relying on the mighty power of money, and using it in utter distrust of the honesty of the other, who, in his turn, exercises every wile to obtain possession of the money, without performing the condition of which it is the price.

The power of Parliament gradually increased through the despotic reigns of the Tudor kings. It is well known that these princes had a wise aversion to trying constitutional conclusions. It was otherwise when the Stewarts came. The lamentable conflict which then broke out, whatever we may say of its origin, became at last a struggle for entire supremacy between Charles I. and his Parliament. To this end the chief object of each was to get possession of the militia or military force of the kingdom. The question had ever before been left open, but each was determined that it should no longer remain so, by arrogating entire possession. How the conflict ended is too well known to be here stated. But it is almost necessary to remind readers that the Protectorate was still a parliamentary government, not a despotism. A succession of scattered notices of the debates and proceedings in the Parliaments held under Cromwell are preserved in the curious *Parliamentary Diary* of Thomas Burton. They show, when compared to the memorials we have of other Parliaments immediately before and after, no lack of independent discussion. They exemplify distinctly, however, the inconveniences of throwing such a body as a Parliament, by revolutionary explosions, out of its fixed routine. By the junction of the two Houses into one, and the abolition of some offensive tribunals, such as the Star Chamber, a quantity of judicial business was thrown on the Parliament to which the procedure in the House of Commons was not adapted. It would be difficult to name at any other period a measure which occupied so much time, and involved so many heavy debates, as the disposal of Naylor, the insane Quaker. At the end of each denunciatory debate came the question, whether there was any law infringed by Naylor; and if so, whether the House were the proper persons to apply it by punishment; and the perplexing debates occasioned by this subject show the wisdom of the House of Commons in having kept clear of all judicial functions both before and since that period.

On the Restoration, Parliament kept to its old traditions. There was little change in its forms until the Revolution. Some important proceedings, affecting its power and constitution, are part of the history of the period. Among these was the repeal of an act passed in 1641, which provided for the assembling of a fresh Parliament within three years after a dissolution, whether the king might call it or not. It was not, however, the failure to call Parliaments, but their too long continuance when called, that became the constitutional vice of the reign. The Parliament which met in 1661 lasted for seventeen years, becoming subservient by long continuance, as its predecessor, called the Long Parliament, had become self-willed from the same cause.

The Revolution of 1688 was, in form, a piece of parliamentary procedure, but it essentially belongs to the general history of the country. In 1694 an act was passed for limiting the duration of Parliaments to three years. The union with Scotland, which soon followed, renders it appropriate to give a sketch of the separate progress of representative government in that kingdom.

Parliament of Scotland.

In Scotland the history of all political institutions is broken in upon by the "War of Independence," in which the country successfully resisted the attempt of the Norman monarchs of England to extend their conquest northwards. Before this epoch there was a close resemblance in the institutions of the two countries, and the vestiges of early parliamentary history in each are in their character identical. There are the same convocations of his principal subjects to attend and advise the king, without any rule from which we can at this day establish the criterion on which they were selected; the same dubious use of the expressions "common assent" and "general council;" and the same professions that certain acts were done by the universal consent of the community. The functions of such assemblages like those of England, involved a mixture of the legislative, the judicial, and the administrative. There are several capitularies of laws of considerable antiquity, but it is doubtful how far they were sanctioned either by a Parliament or by any less formal assembly. After the death of Alexander III., an arrangement was made for marrying Margaret, the heiress of the Scottish throne, with Prince Edward of England. It was agreed to by a small Scottish Parliament, which, of course, assembled without any royal warrant. The place of meeting was at Brigham, on the English side of the border; and the assemblage "consisted of the four guardians, two of whom were bishops, of ten other bishops, twelve earls, twenty-three abbots, eleven priors, and forty-eight barons." (Innes's *Preface to Acts of Scotland*, § 7.) The marriage was frustrated by the shipwreck of the princess, so well known as the "Maid of Norway," on her way to Scotland. The claims of Edward, and the selection of Balliol from among the competitors to the throne, as the one most complacent, followed. We are told that "The Parliament assembled by John Balliol at Scone, on the 9th of February 1292, was probably the first of the national councils of Scotland which bore that name in the country at the time, although later historians have bestowed it freely on all assemblies of a legislative character. We have no reason to believe that any change in its constitution occasioned the adoption of the new term, which soon became in Scotland, as in England, the received designation of the great legislative council solemnly assembled." (Ib.) Balliol had afterwards a treaty with France, which, along with those of certain bishops, earls, and barons, bore the attesting seals of six burghs,—a fact which would show the admission of this order to Parliament were it certain that there was an assembling on the occasion of those who appended their seals to the treaty. "Finally, in the famous Parliament at Cambuskenneth, held on the 15th day of July 1326, when Bruce claimed from his people a revenue to meet the expenses of his glorious war, and the necessities of the state, the tenth penny of all rents, according to the old extent of King Alexander III., was granted to the monarch by the earls, barons, burgesses, and free tenants in full Parliament assembled. The change had taken place silently and perhaps gradually; but henceforth, undoubtedly, the representatives of the burghs formed the third estate, and an essential part of all Parliaments and general councils." (Ib.)

It is from this point that we find the forms and character of the Scottish Parliament gradually diverging from those of the English. But before describing the nature of these divergencies, it may be proper to mention a constitutional change copied directly from the Parliament of England, and not on that account throwing any doubt on the divergence in question, but rather establishing it by the marked and specific character of the exception. An early statute of the reign of James I. abruptly enacts, "That the small barons and free tenants need not come to Parliament nor general councils;" and these were appointed in their several counties to choose representatives,—two for every county, with the exception of a few small counties, which were to have but one. These representatives are called in the act the "speakers;" and their constituency being spared attendance, were bound to contribute to the necessary ex-

Parliament

Parliament of Scotland.

pense of sending them to Parliament. The ecclesiastical dignitaries, with "the dukes, earls, lords of Parliament, and banrents," were to continue to be summoned to Parliament by "special precept," like the special summons issued to the lords, according to the practice then old in England. It has often been said that this act, with other measures introducing English practices in the reign of James I., may be attributed to that monarch's residence in England during his youth. Whether introduced by the monarch himself or not, this measure, though it brought into Scotland an English practice, is in striking contrast to the tenor of English legislation, which avoided positive enactments on constitutional questions of this kind.

While representatives from the towns, and the lesser barons or freeholders, were thus constituent elements of the Parliament of Scotland, this body never came to be divided like the Parliament of England into two Houses. The high ecclesiastics, the lords who were there by special precept or writ, the representatives of the freeholders, and the representatives of the citizens of royal burghs,—all sat in one hall. The officers of the Crown had conspicuous places in this Parliament in virtue of their offices, but had no vote unless they were otherwise members; but they had, in general, seats as ecclesiastical or temporal lords.

What may be called the opening scene of the French Revolution was the question, whether a measure was to be carried in the three estates by a general numerical majority of the whole members, or by the approval of all the estates, carried by a majority of the members of each. This question appears to have remained undecided in Scotland (where also it became usual to call Parliament "the Three Estates"), down to the debates on the Union. Perhaps the question was avoided; for, in the instances where divisions are recorded, it is usual to find a majority—sometimes the narrowest possible—in each estate. It is certain, however, that among the many divisions on the Treaty of Union, there are some in which there is a minority in the lords or barons, though a general majority of the whole Parliament is recorded.

That revision of a measure which the English Parliament had found in its transference from one House to another, the Scottish Parliament seems to have sought through a supreme committee administering in Scotland, in some measure, the function of the House of Lords in England. This committee was called "The Lords of the Articles." It appears to have been for a long time the result of fair election, each estate choosing a certain number of its members. Subsequently, however, it gradually merged into a complicated adjustment, which made the Lords of the Articles rather the ministers of the Crown than a department of a free Parliament. Thus, in the days of the later Stewarts, the bishops began the election of Lords of the Articles by choosing eight lords. These, in their turn, chose eight bishops. The sixteen then selected eight county and eight burgh members. These thirty-two did all the work of Parliament. The Estates had scarcely any more opportunity of acting at large throughout a whole session of Parliament than in one meeting to select the Lords of the Articles, and in another meeting to pass the acts which these proposed for their acceptance. While, however, the conducting of their business through a body so small, and so equivocally constituted, brought the Scottish Estates much under the influence of the Crown, they had their own peculiar elements of independence different from those enjoyed by the English Parliament. In England two things came to be matter of very strict constitutional practice; first, that Acts of Parliament could only be passed by Parliaments summoned by the Crown; and, second, that all acts of Parliament must have the royal assent, otherwise they were not law. Neither principle was established in Scotland. The most important Parliament that ever met there—the Parliament which abolished the power of the Church of Rome, and virtually carried the Reformation—had no royal sanction. There was no solemn form for administering the royal assent to a measure. A practice had grown up of touching acts of Parliament with the sceptre, but it was often maintained that this was a mere formal courtesy, by which the sovereign acknowledged the existence of an act passed by the Estates, and announced that he had no objection to it. Some of the older acts were passed with so little deference to the sovereign's will, that it was considered immaterial whether he touched them with the sceptre or not. So lately, however, as Queen Anne's reign, when the Act of Security was passed for severing Scotland from England, it was maintained by some of the members that, if the policy then prevailing in England should continue, when the touching of the sceptre was refused, the States had the inherent right of making it law without any royal assent, and would do so.

The Union.

This was one of the events which brought on the Union. The Estates had in the meantime been freed from the Lords of the Articles, and other restraints, by the Revolution, which had at once converted them into a body possessed of all the English freedom of debate, without those rules of parliamentary action which had made the conduct of business so strict in England while debate was free. Many causes of fierce dispute arose between the two nations, among which not the least formidable were proceedings by the English Houses of Parliament for inquiry into matters which occurred in Scotland. The Scots were denied participation in the English shipping and colonial privileges; and when they endeavoured to establish a colony of their own, its promoters—members of the Scottish Estates—were called before the English Parliament to answer for an invasion of the privileges conferred on English commercial companies. The Scottish Estates threatened to form alliances and connections of their own; and it was obvious that nothing but their union with the Parliament of England could keep peace between the two countries.

A union had not only frequently been discussed, but had twice been deliberately attempted,—in 1667 and in 1703. In both instances, the insuperable impediment was, the peculiar commercial fanaticism long peculiar to England. The Scots were by the Navigation Act as incapable of participating in the trading privileges of the English as any other foreign nation, and Parliament refused to admit them to advantages for which it was alleged that they could give no equivalent. The necessity, however, of making both nations one in all respects was now felt, and the leaders of the English Parliament were prepared, with reluctance, to remove the great impediment to a fusion. The terms of a treaty were first adjusted by commissioners appointed for either country by the Crown. When their labours were ended, the far more difficult process began of passing two acts of union which should be identically the same,—one in the Parliament of each country. A process so thoroughly constitutional, and so indicative of the flexibility as well as power of representative government, was never attempted or conceived in any other country. The matter was first taken up in the Parliament of Scotland; and it was some gratification to the national pride to be in a manner laying down the terms of the joint measure to England. In Scotland it is well known that the measure was passed only after a long and stormy contest; in England it was carried more rapidly and easily.

The first Parliament of Great Britain met on October 23, 1707. The members for Scotland, who had been accustomed to rule in a smaller assembly, suffered from a consciousness of insignificance, which naturally merged into a suspicion that they and their nation were subject to the contempt of their great partner. The government and the English members were neither skilful nor successful in removing this impression, and the united Parliament be-

Parliament

gan with evil auspices The Scots, however, soon discovered that they could wield a power readily revealed to parliamentary groups, however small, when they are compact. They learned the art of throwing themselves into one of the scales of nicely-balanced parties; and no ministry could safely venture to rouse the united enmity of the members from the north.

Parliament of Britain.

Two events in parliamentary history followed quickly on the Union. The high Tory government of Harley and St John, being weak in the House of Lords, got a sufficient number of peers created to afford them a preponderance; twelve were created at once, and, in the year 1711, nineteen in all. The effect of this operation was little anticipated. It was remembered as a precedent in 1831; and a threat to repeat it is believed to have carried the Reform Act. The other great constitutional measure was the passing of the Septennial Act. It immediately followed the rebellion of 1715, and its avowed object was, to keep in power the party and the Parliament which had steadily supported the Hanover interest. When the seventh session of that Parliament was near its end there were serious proposals still to prolong its existence, but they were fortunately abandoned.

We now come to a period when the British legislature stands charged in history with the weight of heavy accusations of corruption. But it is, at the same time, the period when parliamentary government made its greatest and its steadiest progress. The House of Commons is indebted for its transcendant power to no one man so much as to Walpole. He encouraged no attempts to grasp at functions which were not constitutionally its own. The prerogatives of the Crown were scrupulously respected, and so were the special functions of the Upper House. But year by year throughout his long administration the representative portion of the constitution increased in importance and power. This increase of influence naturally gave much temptation to corruption. Both the Crown and the aristocracy found it of more avail to wield an influence in the House of Commons than to exercise what remained of their own legitimate authority. Decaying corporations had been wont listlessly to drop the privilege of representation as too heavy for their custody, but now any village or ruined wall, around which the shadow of old electoral rights continued to cling, was sedulously looked after and protected in its franchise by powerful hands. Soon after the middle of the century the influences thus created were loudly condemned, and parliamentary reform was demanded by a large body of statesmen, foremost among whom was Chatham's ambitious son. How the French revolution frightened them from the field, and postponed the question, are matters well known in history.

Parliament of Ireland.

Meanwhile the position of Ireland, as a separate country, with a separate legislature, created uneasiness. It is unnecessary to trace the constitutional progress of the Parliament of Ireland, as it was shaped on the model of the Parliament of England. Having shown a strong partiality for the cause of the White Rose, the Irish Parliament was, on the accession of Henry VII., subjected to a condition of humiliation and dependence by the act called Payning's Law, or the statute of Drogheda. It provides, among many minor restraints, that no legislative proposals could be brought before the Irish Parliament unless they had previously received the approval of the king and his council in England. While this restraint on independent legislation was in full force, the English Parliament claimed and carried into effect the right of legislation for Ireland within the walls of St Stephens. These tests of dependence lasted until they were swept away by the organized force of the Irish volunteers. The independent Irish legislature became then a very formidable body. It was adorned by the eloquence of several men, whose high genius only served to raise party ferocity, and the stormy debates of the evening were often concluded by bloody duels in the morning. A spark from continental conflagrations, among such materials, might at any moment be fatal; and the Irish leaders, taking example by the tactics which had been so effective in Scotland, spoke of regulating the succession to the crown of Ireland, and about separate alliances with powers hostile to England. All the energy of the government of the day, both in England and Ireland, was brought to bear on the emergency. A union was carried amid a storm more formidable than that of 1707, and the United Parliament of Great Britain and Ireland began with the nineteenth century.

The Reform Act.

The next great epoch in parliamentary progress is that of the Reform Act. The substance of the measure will be dealt with in the pages which follow; and the events connected with its passing enter too largely into the general history of the period to be recorded here. The principal portion of the measure—the bill to amend the representation of the people in England and Wales—received the Royal assent on the 7th of June 1832. It is not becoming to indulge in political discussion in a work of reference, but the Reform Act is no longer a matter of politics but of history. It receives the acquiescence and homage of all parties, and therefore there is nothing invidious in saying of it, that no one legislative measure ever did so much to secure good government, official honesty, general freedom, and national prosperity.

Parliament of the United Kingdom.

The Parliament of the United Kingdom of Great Britain and Ireland consists of the Sovereign,—king or queen,—the House of Lords, and the House of Commons. Sometimes these are called the Three Estates of the Realm; but it is more usual, as it used to be in France and in Scotland, to speak of the Bishops or Ecclesiastical Estate, the Lords, and the Commons, as the Three Estates. Each of the three departments of the parliamentary constitution has, as will be more specially explained, separate rights and powers. The Sovereign has his prerogative; the House of Lords has its judicial power; the House of Commons —the least endowed with any authority separate from its legislative combination with the others—has, as the House of Lords also has, powers for the maintenance of its privileges, for compelling the appearance before it of persons whom it desires to examine, and, generally, for extracting the information necessary for conducting the national business. In the functions which are purely legislative, however, all the three powers must act together.

House of Lords.

The House of Lords is usually divided into lords spiritual and lords temporal, and both again are divided into lords who sit there by absolute right, and lords who are selected. The English bishops, though called lords spiritual, are believed to sit in virtue of their temporal baronies; and one of them, the Bishop of Sodor and Mann, whose see was beyond the bounds of the old Norman baronies, has hence no seat in the House. Four bishops are selected to represent the Church of Ireland, in terms of a rotation established at the Union. The temporal lords who sit by their own right are the peers of England, the peers of Great Britain, created since the union with Scotland, and the peers of the United Kingdom, created since the union with Ireland. There is no limit to the royal prerogative in the creation of hereditary peers of the United Kingdom. It has been, however, questioned whether the Crown can create a peerage merely for life, and the question created so grave a controversy when that honour was conferred on Lord Wensleydale, that the patent was altered to the usual form.

We have seen that the first members of the House of Lords sat by tenure of their lands. The question of the right to sit by tenure alone, is still in one sense undecided. It is true that since the peerage came virtually to consist of titles

Parliament House of Lords.

by writ, no claim to membership has been admitted on the ground of tenure. But it is equally true, that there is no law or solemn decision declaring that tenure forms no title. It is a popular belief that certain great feudal domains—as Arundel and Berkeley—still possess the virtue of conferring peerage on their owners. The question has slept, owing in many instances to this obvious cause, that the person who would be baron by tenure, is an earl, or something still higher, by writ. Various accidents, not unaided by design, have prevented the question from demanding a decision in some special cases. In the instance of one family—the Berkeley's—it appeared to draw to an issue more than once, but has always been incidentally checked; and it has been just again opened by the owner of the ancient domains of that family, who has presented a petition claiming his right to sit as a baron by tenure. The elder children of the last lord who held the title were found to be in law illegitimate, and incapable of succession to the peerage by writ. He, however, bequeathed to the eldest and the second of these children successively the castle and domains. The exclusion of the elder children of course opened the succession of the peerage to the eldest son born in wedlock; but, from an honourable homage to the memory of his parents, that son, holding, it would seem, that the decision which illegitimated his elder brothers was unjust, has refused to assume the title. When the eldest son succeeded to the domain, the question whether he could sit as baron by tenure might have arisen, but was obviated by his being raised by patent to the peerage as Earl Fitzhardinge. On his death this title became extinct. The second son succeeded to the estates, and the family title by writ still remained unclaimed. In these circumstances, the owner of the estates demands to be admitted as a baron by tenure. The claim involves the principle of territorial nobility in its simplest form; for the conditions which deprive him of succession to the earldom of Berkeley by writ, would also disqualify him as the representative of the previous owners; and the title by which he holds the estate is not more hereditary in its legal character than that of any stranger obtaining it by bequest or purchase might be. In this case the applicant has stated to the Committee of Privileges of the House of Lords, that the lordships of Berkeley could be traced as a tenure by barony to the reign of Henry I.; and that the muniments of the lordships were so well preserved, "that he should be able to bring before the House almost every one of the barons of Berkeley, and make them declare that they held their titles by tenure; and it was by tenure they were entitled to sit as lords of Parliament." He has offered to prove that, before passing into the present family, the estates had been appropriated by the Crown; that, consequently, those who had possessed them then ceased to be lords of Parliament; and that there were lords of Berkeley in Parliament at all times when those lands were in the possession of a subject, and none when the lands were in the hands of the Crown. He was farther prepared to show that, during the Tudor dynasty, the estates having been entailed, went to an heir of entail who was not the lineal descendant of the former holders; and that, by reason of the possession of the property, that heir of entail sat in the House of Lords as owner of the barony. If this case be brought to its legitimate conclusion, it will settle the question whether lordship by tenure is an existing right under the British constitution.

The old peerage of Scotland is represented by sixteen of that body, chosen for each Parliament. The peers entitled to elect them are those who, whatever other dignities they may enjoy, are in the possession of titles acknowledged in "the Union Roll" made up at the time of the union with England. The Irish peerage sends to the House twenty-eight representatives, chosen for life.

Parliament House of Commons.

The House of Commons consists, besides the representatives of the universities, of the members for counties and the members for towns. In England and Ireland the former are technically called knights of the shire, and the latter burgesses. In Scotland both classes were, by old custom, called "commissioners;" but the peculiarity has been, in practice, dropped.

The following short statement of the several kinds of franchise throughout the empire is intended not so much to furnish a technical legal definition of the different qualifications to vote, as to convey a general notion of the classes who possess the franchise.

The franchise in England.

In the English counties the forty-shilling freeholders are the foundation of the constituency. Freehold estates, as distinct from other kinds of landed property, are those held directly of the Crown. The expansive character of this qualification was limited by the Reform Act, which requires occupancy if the freehold interest be only for life, unless it has come by marriage or settlement, or is attached to an office. The absolute freeholds which confer the franchise are called freeholds of inheritance. The virtual meaning of this is, that they have either descended as property to the holder, or that they are absolutely vested in himself and his heirs—in short, that he is owner of the freehold; for although, technically, that is not a freehold of inheritance which does not go to the heir, of course the conveyancer who completes the title for a purchaser will see that it is so adjusted as to convey to him an available freehold. Those who were in possession of life freeholds at the time of the passing of the Reform Act retained the franchise, but their number must now be much reduced, and gradually becoming extinct. Of the large class specially enfranchised by the Reform Act, the more important are, the possessors of land worth L.10 a year on any title not freehold, such as copyhold, or on lease for sixty years; and the possession of leases for twenty years of lands worth L.50 a year. The franchise derived from the possession of lands of the annual value of L.10 and L.50 respectively must be an actual interest to that extent, and therefore must be clear of all rents and charges; such are the qualifications by ownership not necessarily inferring occupancy. Another large class consists of those who are the tenants and occupants of lands paying a rent of L.50. No one can hold a county vote on the freehold of a tenement, which would give him a right to vote in a town whether he exercise that right or not; and no one can vote for a county on property other than freehold, if it give the right of voting in a town.

In the English towns the right of voting was infinitely varied—in some instances comprising a closely limited body, in others indefinitely expansive, and sometimes comprehending a great part of the least educated and least orderly classes of the community. The most comprehensive class of these electors has been well known by the name of freemen. (See MUNICIPAL CORPORATION.) In those towns which were not disfranchised by the Reform Act, the freemen on the list immediately before the passing of the act were, under certain restrictions, allowed to retain their right to vote. None could afterwards acquire the right to vote as freeholders unless through birth or servitude; and no one can derive it by birth unless his predecessor held it before the passing of the Reform Act, or acquired it by servitude. Another class of voters in the English towns were the holders of freeholds and burgage tenements; a class capable, like the freemen and the county freeholders, of being sometimes fictitiously extended. This class of voters was retained under conditions for preventing the creation of fictitious votes. These required that the voter should be in receipt of rents and profits for a year, unless when the property had come by descent or settlement, and likewise that he should reside for six months in the town or its neighbourhood. To these a

Parliament

large distinct class of voters was added by the Reform Act, who, while they form the majority in many of the old constituencies, are the entire constituency of the newly enfranchised towns. They are the now well-known ten-pound householders—the occupants, whether as owners or tenants, of premises worth L.10 a year. There are provisions requiring that the qualification shall have been enjoyed for a whole year before it is acted on, and for residence for six months in the town or its neighbourhood.

The franchise in Scotland.

The constituency of Scotland is far more a fundamental creation of the Reform Act than that of England. It is hence naturally much more simple. Of the old county constituencies of freeholders, those only who had the qualification when the act passed are now entitled to vote on their freeholds; and of course their number must be much reduced. The fresh constituency consists of—1*st*, Owners of heritable or landed property worth L.10 a-year, clear of charges. Every kind of title, implying ownership of land, or its profits, is, by the spirit of the definitions in the act, capable of conferring a qualification, with the exception of those rights which, though nominally of a proprietary nature, are in reality only securities over the property for debt. 2*d*, Tenants on leases not shorter than the old customary period of "three nineteen years," or fifty-seven years—who have a proprietary interest in the lease worth L.10 a-year. Though the law of Scotland strictly separates this class of holders from feudal proprietors, in relation to whom they are mere tenants, yet their position has a virtual analogy with that of some of the English yeomen or peasant-proprietor class, and, like them, the Scottish tenants on long leases are qualified without occupancy. 3*d*, Tenants in occupancy, paying a rent of L.50, or who may have paid the sum of L.300 in the shape of "a grassum"—nearly equivalent to a "fine" in England—as the consideration apart from any rent. The town constituencies of Scotland were entirely framed by the Reform Act, as the old arrangement was not a system of direct representation—the elections being made by the corporations, as a sort of electoral colleges, representing the citizens. There is but one source of qualification—an urban tenement worth L.10 a-year, whether it be a dwelling-house or place of business. Such a tenement gives a qualification, either on occupancy as proprietor or tenant, or on ownership without occupancy. There are conditions of a year's possession, and a half year's residence in the town or its neighbourhood, similar to those in England. One peculiarity has been retained from the old system, which, though it does not affect the qualifications of the electors, makes the Scottish burghal representation differ materially from the English and the Irish. The small towns are grouped together in districts;—for instance, the St Andrews district embraces seven small towns,—an arrangement which obviated the two alternatives of giving an undue preponderance to small burghal constituencies on the one hand, and on the other absorbing them in the counties.

The franchise in Ireland.

In Ireland, the forty-shilling freehold system having been a means by which a landlord could give a vote to all his adult male tenants, was restrained as a condition of the Catholic Emancipation Act; and, saving some existing rights to the individual holders, the qualification was then raised to a ten-pound freehold. The Reform Act added to this constituency a similar amount of property held by copyhold, a ten-pound interest in a lease for a term of sixty years, or a twenty-pound interest in a lease for fourteen years if terminable on a life, a ten-pound interest in an absolute lease of twenty years, and the occupancy of such a tenement by sub-lease. In the Irish towns, a residue of freemen and voters holding under other consuetudinary franchises, had to be curtailed by the Reform Act, and the staple of the qualification for voting became the ten-pound occupancy.

Qualification of voters.

There are arrangements in the several divisions of the United Kingdom for preserving an authentic register of those entitled to vote. An explanation of these arrangements would lead to technical details. It need only be stated that the establishment of certainty in this matter, with the requisite expedition, has been attended with great difficulty. If analogy had been taken from the law of private rights, the voter claiming a disputed interest in property, might be dragged through a litigation as long as any that is necessary for establishing a disputed title. On the other hand, so long as a patrimonial interest is counted the proper foundation for a vote, it could never be permitted to every one to claim the right without becoming liable to challenge. To accomplish a practical medium suitable to the purpose, the lists are made up on the statements of each applicant, supported by ordinary documents, such as leases, receipts, &c., which give a colour to his claim, and, if it be objected to, there is a summary judicial settlement or revisal. While professional judges have been employed in this function, care has been taken to bar all cases of disputed qualification from entering the courts as regular litigations. Party zeal is generally sufficient to make this ordeal pretty stringent, and the purgations of the roll have in some measure the aspect of a litigation between two sides, to which the rights of individual claimants of the franchise are in the position of items in accounting, which are struck off or kept on, on either side respectively, according to the success of the attack or the defence.

It need scarcely be said that none are qualified to hold the franchise but males twenty-one years old. Insanity and idiotcy are good grounds of objection to claims for enrolment, and so are convictions of perjury or bribery. A large body of persons in the government employment—chiefly embracing those connected with the revenue—are disqualified by Act of Parliament, and so are the holders of government contracts. The official persons connected with the metropolitan police force are likewise excluded from voting within the metropolitan districts. In the cases not thus specially provided for, government employment is no disqualification. No alien can vote for a member of Parliament, at least in England or Ireland. Practically the same exclusion extends to Scotland, but it has been questioned whether there is anything in the law of Scotland to support it.

Qualification of members.

As to the qualifications of candidates: In the first place, no member of the House of Lords is eligible to the House of Commons. The representative peers of Scotland and Ireland are of course excluded. No peer of Scotland can, however, be elected; and it may be said that a Scottish peer, not one of the representatives in the House of Lords, belongs to the only class of men in the British empire who are ineligible to the House of Commons. Their heirs were formerly excluded, but this disqualification was removed by the Reform Act. The judges of the supreme courts are ineligible. In England their exclusion is attributed to their restricted privilege of presence in the House of Lords. The Scottish judges are excluded by a statute passed by Walpole to keep out of Parliament a judge of the Court of Session, the notorious Erskine of Grange, whom he expected to be troublesome to the government. The holders of all government offices created since the year 1705, are by statute ineligible. The great offices of the ministry which date from before that year are of course not within the exclusion, but their holders, if in Parliament when they take office, require to be re-elected. When the war department was lately re-constructed, a special act was necessary to enable the under-secretary-at-war to sit in the House. The clergy of the Church of England and Ireland are excluded in a body. The absolute character of this exclusion was tested in a resolute contest by Horne Tooke,

Parliament

whose commentary on the result was, that a man once admitted to orders could only get admission to the Commons by leading a life which might procure his degradation from the priesthood. There prevails a sort of traditional doctrine that the clergy are excluded from Parliament as the lay council of the kingdom, because they are represented in convocation—the clerical council. The exclusion does not, of course, apply to the clergy of Protestant dissenting bodies. Whether there could be any ground for preventing a clergyman of the Established Church of Scotland from sitting in the House of Commons, is a question which does not appear to have been put to a practical test. There would perhaps be no opportunity of deciding it in the case of a minister ordained to a charge, because his removal to such a foreign field of duty as the legislature would doubtless be a ground of deposition. But a licentiate or a retired beneficed clergyman would be excluded were the strictness of the English rule applicable to the Presbyterian Establishment. By the Catholic Emancipation Act, no Roman Catholic priest is capable of being elected a member.

The disqualifications which operated formerly against lay Roman Catholics, and till lately against Jews, were of a different kind. There was nothing to render them ineligible, but certain oaths which they required to take before sitting and acting stood in their way after they were elected. The Emancipation Act removed this barrier from the Roman Catholics, by repealing the provisions which required members of Parliament to abjure some of the fundamental principles of that church. The oath of fidelity, which required to be taken on the faith of a Christian, had still the effect of restraining honest members of the Jewish persuasion from sitting. The removal of this impediment has been the object of a long and arduous contest, in which it was maintained on the one hand, that if the legislature meant to exclude Jews from Parliament they should so enact specifically, instead of leaving them to suffer from the accidental effect of a provision not directed against them; while those who thought that Jews ought to be excluded from the legislature were not of course inclined to give up the practical hold which the accidental effect of the clause gave to them. Repeated measures of relief, in various shapes, were passed by the Commons and rejected by the Lords. At length the friends of Jewish emancipation followed the example which the sagacity of O'Connell had set in the battle of Catholic emancipation, when he got himself returned for Parliament for the county of Clare, and was excluded by the oaths. For several years an eminent member of the Jewish persuasion has been one of the members elect for the city of London. A large constituency deficient in its full complement of representatives through the working of a law which can be altered, would naturally be the most powerful method of bringing home a great principle to the practical mind of British statesmen. It prevented the question from ever falling asleep. Various efforts were made, virtually to effect relief within the House of Commons itself, as a question between the House at large and an individual member. These brought out some curious points in the constitutional practice of the House, but did not effect their object. The House got so far as to permit the Jewish member to take the oath on the Old Testament, as being more binding on his conscience than the whole Bible; but no means were found for safely dispensing with the terms of the oath which were laid down in an act of Parliament. Had the way through other legal difficulties been quite clear, the sitting and acting without having taken the oath involved legal penalties which the courts of law could enforce, and from which the House of Commons could give no protection. In the summer of 1858, the House of Lords submitted to a compromise of a peculiar character on this point. The restraining clause in the oath was not removed, but power was given by statute to the House of Commons to dispense with it by resolution in those cases where it thought fit so to do. The same act gave the House of Lords the same privilege towards Jews raised to the peerage. This act came into operation in July 1858.

Under the head of qualification, it may be stated that there are arrangements for vacating the seats of members who are convicted of crimes, or become insane, or come under the bankruptcy acts. The method of procedure in disqualification by bankruptcy is carefully laid down by statute. Any power assumed by the House itself to exclude the member whom a constituency choose to have as their representative, has always been contemplated outside the walls of Parliament with a jealousy which has been responded to by a corresponding caution within. However offensive any member may become in the House, to deprive a constituency of their representative, duly elected and legally qualified, is a far more serious arrogation of independent power than the refusal to repeal a law which may prevent him from acting. The last instance in which a member was expelled, on account of the general disgust felt towards him by the members, was the notorious case of Wilkes, and the proceeding was vitiated as a precedent by its subsequent revocation, and the admission of its object to the House. Formerly in England and Ireland a candidate required to qualify himself by declaring, if he stood for a county, that he had an estate of L.600 a year, and if for a town, that he had an estate of L.300 a year. This part of the statute was repealed in 1858.

Number of the Commons; proportions to population.

The number of members at present eligible to the House of Commons is 654. It need scarcely be remarked that, from the pressure to obtain seats, vacancies are seldom allowed to remain longer than the time necessary for filling them, and that, whatever the attendance may be, the House is always, with brief and limited exceptions, complete. The numbers are thus distributed:—In England, including Wales, there are 159 members for the counties, 4 for the universities, and 333 for the towns. These last, until lately, amounted to 337, but the disfranchisement of Sudbury and St Albans by statute, for corruption, has reduced the number. In Scotland there are 30 members for counties, and 23 for towns. In Ireland there are 64 members for counties, 2 for the University of Dublin, and 39 for the towns.

It was one of the objects of the Reform Act to render the proportion of representatives to population in the different constituencies of the empire less unequal than it had been. Still, it is not professed that either the extent of population, or the number of electors, has been made an absolute criterion in the distribution of representation. That there should be a closer proportion between population and representation; that the proportion should be rendered practically absolute by a flexible plan for adjusting the representation from time to time to the relative changes in the population; these are among the political questions of the day. As such it would be inappropriate to deal with them in a work of reference, farther than by the statement of any facts which may show the extent of ground covered by the controversy. The greatest inequalities are in the town department. In England, Harwich, Knaresborough, Marlborough, Ludlow, Thetford, and Totness, with fewer than 6000 inhabitants, have each two members; while Glasgow, with a population of 350,000, has also two members. London, though divided into seven electoral districts, one of them with four representatives, sends only 16 members to Parliament from a population exceeding two millions. In fact, nowhere else in the United Kingdom is there an area containing within it so large a population with so narrow a representation; for while Scotland is on the whole not so fully represented for its numbers as England, yet for a population not quite three millions there are 53

Parliament

representatives. The area making the nearest approach to London for greatness and density of population is perhaps the manufacturing district of Lancashire. The population of that county (including the trifling rural population on its moorlands) just exceeds two millions, and for these there are, including the four county members, twenty-six representatives. In England, indeed, it will be found that where the proportions of the populations of towns to each other would be indicated by an enlargement according to geometrical progression, the increase of representation would have a nearer ratio to arithmetical progression, and among the small English boroughs a population of 50,000 might be found returning as many members as the metropolis. The inequality in the English counties is not nearly so great. It is true that none of the large counties, Yorkshire excepted, has more than four members, but the smallest county returning two members has a population exceeding 20,000. The relative proportions of electors and of members to population in the three kingdoms, as compared with each other, having sometimes been an object of discussion, the following general results may be stated in round numbers:—In the English counties there is 1 elector for each 20, and 1 member for each 66,012 inhabitants; in the counties of Scotland there is 1 elector for each 34, and 1 member for each 57,554; in Ireland there is 1 elector for each 40, and 1 member for each 93,127 of the population. Taking the town constituencies, we find in England 1 elector for each 17, and 1 member for each 22,088; in Scotland 1 elector to each 23, and 1 member to each 49,397; and in Ireland, 1 elector for each 30, and 1 member for each 21,425. Even when the exclusion of the fractions is granted, this statement can only be taken as a general estimate of proportions, since the populations are taken from the census of 1851, and the numbers of members and electors are taken from a return ordered by the House of Commons to be printed in February 1858.

Summoning Parliament—General elections.

The summoning and the dissolution of a Parliament, as well as the calling and adjournment of it from time to time, are among the undoubted prerogatives of the Crown. When a new Parliament is to be summoned, the lord chancellor receives a written command from the sovereign in council to that effect, and directs the clerk of the Crown in Chancery to issue writs to the several electoral districts. The writs, whether for county or town elections, used to be issued to the sheriff of the county. In England the return of the person elected in a town is generally made by some municipal officer, and by a late act the writs are immediately transmitted to that officer. There is necessarily some variation in the time within which elections must be completed in the different parts of the empire; but the general rule of late has been to abbreviate the time. In England, in counties, the returning officer must, within two days, fix a day, not less than ten, or more than sixteen, for the election. In boroughs it must be within six days, and on three days' notice. The day being fixed, the writ is read in public by the returning officer, and candidates are proposed and seconded by qualified electors. A show of hands is taken, and the returning officer declares the apparent result, without of course knowing whether those who have held up their hands are electors or not. If the parties are satisfied with this declaration the election is at an end; but if the partisans of any candidate proposed are determined on a contest, they crave a poll, and the return is not declared or made until this is over. Formerly the operation of polling used in England to be spread over a period which might amount to fifteen days. Opportunities were thus afforded for deadly contests and very corrupting practices. The opinion that has ruled the later legislation on election practice is, that when the operation is short and simultaneous, the chances of undue influence and violence are reduced, and those of a fair uninfluenced majority in numbers increased. The polling period was abbreviated by the Reform Act, and it is now in the general case limited to one day. There are, at the same time, arrangements for the multiplication of polling booths and stations, to the effect that all electors may give their votes in a free and orderly manner, without requiring to press forward in crowds. The qualifications of voters used in the days of long elections to be subjected to inquiries and discussions, which created small law suits at the polling places. The matters which may be inquired into and discussed, before a tendered vote can be recorded by the poll-clerk, are now strictly limited to the identity of the person voting as a voter on the roll, and his still possessing the qualification on which he was enrolled. A person who generally belongs to some legal body presides at the polling booth, where he is assisted by a recording clerk. If overpowered by a mob, the polling officer adjourns the polling, and resumes it when it can be carried on without disturbance. In pursuance of an old constitutional principle, any military force that may happen to be stationed in a town where there is an election must be removed till it is concluded. At the end of the polling the books are brought sealed to the returning officer, who sums them up. It rarely happens, however, that through the vigilant attention of the supporters of the candidates the result fails to be known to the public with perfect accuracy; and it is usual to post up the numbers in conspicuous places from time to time as the contest draws on. The result is declared at the hustings by the returning officer; and it is usual for the candidates, and sometimes their friends, to make speeches on the occasion. The election is returned to Chancery, but the candidate is considered to be a member of Parliament from the moment of the declaration, although he does not act as a legislator until he has taken the oaths.

The Speaker.

The first important business of a new Parliament, as distinct from the opening of a new session of an existing Parliament, is the choice of the Speaker of the House of Commons. A commission, with the lord chancellor at its head, announces that the sovereign will state the cause of the calling of the Parliament, when the members are sworn in, and requests that the gentlemen of the House of Commons will proceed to the appointment of some proper person to be their speaker, and present him for the royal approval. The selection and confirmation of a speaker used to be attended with many ceremonious professions of urgency on the one part, and reluctance on the other; and it was even usual to place him in the chair by gentle compulsion, he all the while professing his unworthiness of the office conferred on him. Some faint vestiges of these practices still continue. The speaker elect goes to the House of Lords, where he receives the royal approval, making profession of his unworthiness, and stating that the faithful Commons are ready to make another choice if he be not approved of. It is still an undecided question whether this is a mere ceremonial of courtesy, or implies a real veto in the Crown on the election of a speaker. It is a question fortunately never likely to be decided, because like many others between the Crown and Parliament it is not likely to be tried. During the reign of Charles II. a memorable dispute occurred on this matter. On the opening of Parliament in 1679, the Court had one of its own followers to offer as speaker; but the Commons selected Sir Edward Seymour, a man of the first rank in their order, who professed to look down upon the Duke of Somerset as a cadet of his family,—pompous, haughty, and extremely jealous of the privileges and powers of the untitled aristocracy who were then, as now, to be found in the House of Commons. He was rejected by the Crown. There is more than one version of the shape in which he reported his election.

The Parliamentary history gives it thus:—"May it please your Majesty, the knights, citizens, and burgesses, in Parliament assembled, in obedience to your Majesty's command, have made choice of a speaker, and have unanimously chosen me; and now I have come hither for your Majesty's approbation, which, if your Majesty please to grant, I shall do them and you the best service I can." By other accounts, however, he is said to have anticipated the courteous declinature of his services by saying,—"That he was unanimously chosen by the suffrages of all the Commons of England to be their speaker; and that he was resolved to serve his Majesty in that station to the utmost of his power." The chancellor who had prepared a speech for the occasion was, it is said, somewhat discomfited by this device, and without the courtesy due to the solemn occasion, after some hesitation and hints from others to remind him of his duty, informed Seymour that his Majesty had other occasions for his service, and the House of Commons must make another choice, and attend next day to report it. The House was then entering on the impeachment of Danby, and this affair added to the prevailing excitement. There was a hot debate on it for a week, followed by a prorogation; and the House, content probably with having loudly asserted its rights, having again to make a choice, selected Mr Serjeant Gregory, who, whether he were really acceptable there or not, was not the person who had been pointed out by the court for their choice.

In the seventeenth century, when the House of Commons had so many contests with the Crown, it was essential that the man who was set by them in front of the battle should not only be possessed of learning, sagacity, and integrity, but of great firmness and courage. Not only as the representative of the House, but within its walls, he had many opportunities either of compromising or of promoting the principles of representative government; for it is evident from Clarendon's admissions, and the general tenor of parliamentary history, that the nature of the House's proceedings could be much influenced by the man who, for the time, occupied the chair. In the present century the utmost that could be said about the influence of a speaker was, that he might occasionally let his eye be caught by a weak member of the opposite party, when there was a speech by a strong member of his own party to be answered. In the peculiar circumstances, however, in which the Whig party were placed by their abrupt and still not fully explained dismissal from office in 1834, they deemed the crisis so important, that it was essential for them to have a speaker from among themselves. They therefore fought the first division of the session on this point, although it was not their strongest, and they had many difficulties to contend with in the position of the government candidate, who had long filled the chair with approval, and had many warm friends. The result of an extremely exciting contest was, that Mr Abercromby was chosen by a majority of ten.

The proper position and functions of a speaker of the House of Commons could not be more emphatically told than in the words of Lenthal, when Charles I., supported by some armed followers, entered the House of Commons, and demanded that "the five members" should be given up. Lenthal, to whom he addressed himself, bent on his knees, and said, "May it please your Majesty,—I have neither eye to see, nor tongue to speak in this place, but as the House, whose servant I am, is pleased to direct me." In adjusting the proceedings and in preserving order, the speaker issues his own directions and commands, but they are in reality those of the House. He is the great depository of the precedents which have been established in former Parliaments; and armed with these, he is prepared to state what the House, in the natural order of things, will require to be done. In the enforcement of his authority, he looks to the support of the House; and if on any point a majority of those present should be against him, his own personal voice would be ineffective. In practice, however, such discussions never arise; and as no man is ever chosen speaker who is not endowed with temper, firmness, and a knowledge of the practice of the House, the speaker's directions are taken as law. The speaker naming a member to the House, is an old established form of censure for disorderly conduct. The only light which Hatsell, in his great work on the precedents of Parliament, can throw on the effect of this mysterious punishment is rather ludicrous. He says,—"A story used to be told by Mr Onslow, which those who ridiculed his strict observance of forms were fond of repeating; that as he often, upon a member's not attending to him, but persisting in any disorder, threatened to name him ('Sir, Sir, I must name you'), on being asked, what would be the consequence of putting that threat into execution, and naming a member, he answered,—'The Lord in Heaven knows,' from whence they collected that it was merely a threatening expression of his own, that would have no consequence at all. He might have referred them to the journal of the 5th of May 1641, or of the 22d of January 1693, where they would have found, 'that if the speaker is compelled to name a member, such member will thereby incur the displeasure and censure of the House." (P. 237.) The last occasion on which this ceremony was performed, was when Fergus O'Connor, having become insane, grew disorderly, and struck the member sitting beside him; but it does not appear to have had much effect.

The necessity of the speaker's presence at the opening and at the conclusion of all pieces of business counted as proceedings of the House, has been observed with an almost superstitious pertinacity until a very few years ago. The immense accumulation of detail business in the House had, in the meantime, rendered necessary the responsible office of permanent chairman of committees. In the year 1853 the chairman of committees was made a sort of deputy-speaker, and it was only then that the country was free from the risk of the public business being interrupted by the illness of one man. How seldom this occurred during the long period when the speaker had no substitute is very remarkable. We read the histories of political movements developed in the parliamentary policy of great statesmen, and in the exciting debates of great orators, without ever being reminded by a sudden pause in the progress of events that their continuance depends on one man's health. The thoroughly practical character of parliamentary proceedings has indeed, from an early time, relieved the speaker of a considerable portion of his attendance. The committees have carried off the greater proportion of the increased business, and even when it is necessary that matters should be transacted by the whole House and their speaker, this officer may be relieved from the greater portion of his attendance, by the House resolving itself into a committee, which reports its proceedings for general adoption.

The House of Lords has no speaker, in the sense in which the term is used in the Commons, as the representative of the corporate existence of the House, whose presence is necessary to the validity of the business accomplished. By a standing order of the House, the lord chancellor, or lord keeper, acts as speaker or chairman when present. When the great seal is in commission, a speaker is appointed by the Crown, generally from the heads of the courts of law; but, in the absence of the regular speaker, the House may appoint a member to that function. It is a curious fact that the speaker does not require to be a member of the House, and that he may be, and on occasion has been, a commoner. He has few duties but those connected with the putting of questions to the House, and he has no

Parliament right to enforce order,—such a function not being deemed necessary in the decorous assembly over which he presides. A chairman of committees is appointed for each session. He is a highly responsible and generally laborious officer, having the superintendence of all the procedure in private bills, and the function of checking all irregularities and undue practices by their promoters.

Annual meeting of Parliament. Parliament meets annually, generally in the month of February, but sometimes for a short session, if emergencies render it necessary, before the close of the year. This annual assemblage of Parliament used to be frequently demanded without success, but it is now as firmly established as any human institution can be. The army exists only from year to year through the annual passing of the Mutiny Act, without which there would be no power of military discipline, and soldiers would no more be subject to command than the rest of the community. The funds for the army, as well as for the administration of justice, and the whole civil service of the country, are voted in Parliament annually. In short, unless the whole complicated structure of our national institutions and our civilization were first to disappear, it is impossible to suppose the assembling of Parliament in any year not absolutely necessary.

Its powers. To the two Houses, and especially to the House of Commons, there is a general responsibility on the part of every authority in the country. It would be difficult now to point out any method of exercising power over the subject, on which responsibility may not be exacted in Parliament. It is long since the sovereign has been represented by a cabinet of ministerial officers, all of them members of one or other House, and the channels through which their subordinate officers are made responsible. The hereditary revenues of the Crown are now accounted for as public property. The "civil list," which used to be a large sum placed in the hands of the Crown for the expenses of the civil institutions of the country, is appropriated to its several purposes. While Parliament has power over the existence of the army, as supplying the funds by which it is maintained, the Crown has hitherto kept the command of the forces. This is exercised through a commander-in-chief, who is not a member of the cabinet, and is not considered to be responsible to Parliament in the same manner as a cabinet minister. It has sometimes, indeed, happened that the commander-in-chief belongs to the party opposed to the existing government. Gradually, however, this authority has lately been coming more and more within the sanction of ordinary parliamentary responsibility, and this process has been greatly quickened by the appointment, in 1855, of a principal secretary of state for war as a member of the cabinet, with an under-secretary, who finds a seat in Parliament. The navy is nominally entirely in the hands of the Crown, and its discipline is conducted, not under a temporary act annually passed, but under a permanent act of the reign of Charles II. Its administration, however, has long been under parliamentary control, by being vested in a commission, the chief, and generally other members of which, are in Parliament.

On the other hand, the power of the Crown has nominally been enlarged in various directions, with the ultimate effect of increasing the responsibility to Parliament. Almost all the public boards, and other minor administrational departments, are responsible to the Secretary of State for the Home Department, who may be called upon to make explanations regarding their conduct in his place in Parliament. Where the functions of any public department have become very important, it has been found expedient to place at its head a minister of the Crown, who has a seat in Parliament. This course was adopted, for instance, towards the English Poor Law Board, and the Board of Health. The British empire in Hindustan arose under the auspices of an irresponsible trading company. It was connected with the general government by the appointment of a Board of Control, and recent events have brought it still more within the nominal power of the Crown, and the real influence of Parliament.

The increase of parliamentary power, during the last half century at least, has almost entirely fallen to the House of Commons. It is there that administrations are annihilated or confirmed, and all great measures are tried. The House of Lords never was the natural birth-place of great popular questions, but it has of late been gradually assuming, to an increasing extent, the characteristics of a committee of revisal on the measures passed by the Commons. It has, in this capacity, to perform the unpopular function of rejection. The long and formidable resistance of the Lords to the passing of the Reform Bill called forth a deal of acrimonious criticism, and the various instances in which it rejected measures passed by the Commons were remembered against it. Since that event, if the Lords have not in any way abdicated their function of revisal, they have come less prominently forward as the rival of the House of Commons. Great debates have become less frequent; and large measures, which the House of Commons and the country eagerly promoted, have not been resisted with the old party determination. The Lords who transact the business of that House are generally veteran statesmen, who have acquired legislative experience by a long career in the House of Commons, and their procedure has become more that of a deliberative council of patriarchs or ancients, than of a legislative body divided into two parties, who are bound to conduct a perpetual contest against each other.

Forms of procedure. The forms of procedure in the British Parliament have not received, as a matter of constitutional study, the attention due to them. Instead of involving mere matters of technical and unimportant detail, they are found, when looked at in their general bearings, to be a machinery bringing to wonderful perfection the art of obtaining collective judgment on any matters, however vague and general on the one hand, and however complex in their practical details on the other. It is remarkable that, while the forms of procedure in the law courts have often been acknowledged on all hands to be foul with abuses, and have been assailed as cumbrous and imperfect after the most accomplished practical jurists have reconstructed them,—the procedure of Parliament has gone on unassailed, but ever silently tending towards perfection, by the application to every difficulty as it occurs of the best practical means of overcoming it. One reason for this curious contrast is, that in the courts of law the opposing and contending parties—the litigants and their lawyers—who have no concern in the making of the forms, are yet entitled to take advantage of every flaw and dubiety in their interpretation, and to plead every available quibble; while Parliament makes its forms solely for the use of its own members, the minority as well as the majority; and both are content to fight their battles on their own numerical strength, without founding on technicalities or quibbles. Still, with all this advantage over the practice of the law courts, the forms of Parliament are a wonderful triumph of the practical genius of the nation. In their substantial features they have long remained unaltered. They appear, indeed, to have been brought almost to their present perfection in the great contest of the Long Parliament, where a larger number of able practical men were engaged than perhaps in any other arena known to history. The people of this country are familiar with the forms of Parliament, because they are adopted or imitated in every corporation or collective body, among whom they appear to be the natural way in which collective bodies of men must necessarily transact their business. Their true aptitude can only be estimated by a comparison with the efforts from time to time made by popular assemblages on the European continent to transact legislative business.

Parliament

Forms of procedure.

The great leading principle in the transaction of business in the British Parliament, and the one which most other assemblies have flagrantly missed, is, that there shall be but one question at a time before the House, and that that question shall simply be yea or nay. However hot and confused may be the debate; however seemingly inextricable the views and the projects of the numerous speakers; yet all resolves itself, through a skilful arrangement, into a simple question of affirmative and negative. Thus, at the conclusion of that memorable debate in which the Reform Bill was carried in the House of Commons, on the 22d of September 1831, the conclusion is recorded in the following brief but very distinct terms in the journals of the House:—

"The question being put 'that the bill do pass,' the House divided—

"The yeas went forth—

Tellers for the yeas...	Mr Kennedy Mr John Wood	345
Tellers for the nays........	Mr Croaker Sir George Clerk	236

"So it was resolved in the affirmative. *Ordered*—That Lord John Russell do carry the bill to the Lords, and desire their concurrence." Although the division-lists of the members are now published, the taking and recording of their votes are still in the same simple form. Before this point was reached, there were of course many previous divisions, and a still greater number of debates, in which resolutions were adopted by concession without division. But, however complex may be the measure or the series of motions before the House, every clearing away of its portions is on a question of affirmative or negative, and can be accomplished in no other form. Although it may sometimes appear, from the tenor of a debate, that one substantive motion is pitted against another, or that an amendment competes with a motion, yet this can never be so in reality. If it were so, it might in-involve the necessity of members voting for a resolution as at all events preferable to its competitor, when they would not vote for it if it stood before them on its own naked merits. As there cannot be two questions voted on, so, of course, there cannot be three or more, although in the debate any number of amendments may be brought up against the original motion. These are disposed of one by one on the vote, if a vote be come to, whether such and such words are to stand part of the question. If there be a majority for any words standing part of a question to be put to the House, then a vote of yea or nay is taken on the question with these words in it. If the amendments are all lost by negatives on their being part of the question, then the original proposal, whatever it be—motion or bill—is stripped of all the counter proposals and variations which the debate has called forth, and a vote of yea or nay can be taken on it. No member can thus be driven to vote for what he does not approve of; for down to the last he may start any other proposition that may please him, and take a vote on it, and he may in the end vote against the original proposal.

A memorable incident in a foreign political assembly may perhaps illustrate the value of this method. In the French revolutionary Convention, each member, when there was a question before the House, stood up and stated in his own words, with or without an oration, what view he took, and what resolution he would vote for, and the officers of the House made up the votes and stated the motion carried, according to the best of their judgment. After the trial of Louis XVI., the sense of the House was thus taken on the sentence to be pronounced, and the voting occupied forty hours. As all the world knows, the decision was death, carried by a large majority. It was often maintained, however, that the votes of many members were recorded for death who did not explicitly pronounce that doom, but were prevented by timidity from expressly declaring against it. In English practice there could have been no such dubiety. A proposition would have been laid before the House, and a vote taken of simple affirmative or negative. The timid might have abstained from voting, but never could have recorded equivocal votes.

The records of Parliament show that this method did not always prevail, and that it was deliberately adopted to remedy the evils of a more slovenly practice. It was probably an improvement on the custom of gathering the resolutions of Parliament from the tenor of the debates after they were over. A practice thus arose, as Hatsell tells us, "for the speaker to collect the sense of the House from the debate, and from thence to form a question on which to take the opinion of the House." So early as 1571, however, it was resolved, as an improvement on this plan, "that from henceforth men making motions shall bring them in writing."

It is essential to the pure working of such a procedure, and is at the same time one of the most important distinctive features of the authority of Parliament, that no piece of composition adopted by a vote of either House can afterwards be subjected to even a verbal alteration. To carry out this rule in the case of bills, the House of Commons stood a protracted contest. In form, a bill always was, and still is, a petition by Parliament, and the act into which it resolves itself is the granting of the petition by the sovereign. Nothing was more natural, therefore, than that an official statement should be made by the sovereign of the nature and tenor of those petitions which he granted. In the fifteenth century there were many complaints by the Commons, to the effect that they had petitioned by bill for such and such enactments, and had been informed that their petitions were acceded to; but when they saw the statute for the session as drawn up and recorded, it contained totally different and sometimes adverse enactments. Nor are such discrepancies wonderful when it is known that the method of adjusting the statutes of a session was for the judges to take the petitions and the deliverances of the monarch, and make the acts of Parliament out of both. The remedy devised for this defect is so old, that Sir Matthew Hale, writing in the seventeenth century, is not sure of the reign in which it was adopted, but says "because sometimes difficulties and troubles arose by this extracting out of the petition and answer, about the latter end of Henry VI. and beginning of Edward IV., they took a course to reduce them, even in the first instance, into the full and complete form."

In pursuance of this policy, at the present day a bill, which has passed both Houses, contains all the sentences, and all the words to be found in the act of Parliament into which the royal assent converts it. The bill may contain a few words which are not in the act, but the act does not contain a word which is not in the bill. In its jealousy of any tampering with the precise tenor of its resolutions, Parliament has been indifferent to the illogical character of the form of an ordinary bill, which begins as a petition, and converts the substance of it into the shape of peremptory enactments.

There are some peculiarities of parliamentary procedure, partly embodied in rules, and partly enforced from a sense of courtesy and propriety, which tend materially to the fairness, and, at the same time, to the practical conclusiveness of parliamentary procedure. Desultory and incidental debates are obviated by the necessity, that when a member speaks, it must be to some question before the House, or his speech must introduce a question. Motions upon public questions require to be seconded—a good rule against interruption and annoyance from eccentric and impracticable members, which is followed in every public assemblage in this country. The mover of a motion is per-

Parliament. Forms of procedure.

mitted to reply to those who have supported any amendment on it before it is put to the vote, but otherwise no one is entitled to more than one opportunity of speaking on a question, except when the House is in committee on a bill.

This is not the place for a discussion on parliamentary orators; but it seems appropriate to remark, that the tendency of the parliamentary, and perhaps of the public taste, has been to discountenance rhetorical efforts, and to listen only to facts, and close reasoning on them. For speeches, such as were delivered a century ago, the pressure of real business leaves no time. On the other hand, it has been said that the entire publicity now given to debates has had a tendency to make many members of the Commons address themselves rather to their constituents than to the House. There are some little peculiarities of old standing in parliamentary speaking which are supposed to be favourable to good order and calm discussion. For instance, no member is to call another by his name; if it is desired to call personal attention to him, he must be individualized by the place he represents. Naming the antagonist in the heat of debate is apt to foster irritation on both sides; and the very necessity for recollecting the constituency which the adversary represents, has a momentary tendency to allay excitement. The views of the proceedings taken by the other members of the constitution, as by the monarch or the House of Lords, must not be referred to; nor can a discussion be opened on a reported debate at a previous sitting.

In the House of Lords there is of course precedence, but in the Commons all are on an official equality. There is a purposed jealousy of etiquettes, as if these were likely to lead to inequalities inconsistent with the character ever held by the Commons of Britain. For the sake of convenience, certain parties—ministerial, opposition, or any other—group themselves on benches which they appropriate to themselves; but this arrangement is carried out entirely by personal choice. There is no tribune such as that which used to be occupied by a member addressing the House in the French Chambers. The ministers of the Crown hold in Parliament a position which foreigners cannot easily understand. They have no special rights, but the conducting of the public business requires that, to a considerable extent, they should dictate the proceedings of the House. This they do through the influence of that majority which places and keeps them in power. The opposition sanction it, for it is not their object to upset the business of the country, but to get it conducted in their own way; and therefore they strive not to interrupt the operations of the majority, but to become the majority, and so conduct the business of the country themselves.

But what is still more characteristic of the British Parliament, when compared with popular assemblies in other countries,—the minority has its privileges as well as the governing majority, and fortunately they have always been deemed impregnable. The standing orders which require measures to pass through certain stages for the purpose of securing deliberation, and giving an opportunity for opposition, have sometimes, it is true, been suspended. On some occasions they have been so for the purpose of strengthening the hands of a government, and even conferring on it arbitrary powers, when it has professed to deal with dire emergencies, and made terror the excuse of precipitation. Such events are now looked back upon as the historical vestiges of evil times. In late years suspensions have rarely occurred, except with the view of mitigating or obviating some calamity, and conferring a boon appreciated by the minority as well as the majority, or else for the purpose of correcting some legislative blunder.

It is fortunate for the country that not only the privileges of weak parties in the House of Commons, but the privileges of individual members are preserved, not only in the letter, but in the spirit. Onslow, one of the most sagacious of the eminent men who have filled the speaker's chair, used to hold that a punctilious observance of the rules of the House was the great protection of the weak from the strong, and hence one of the safeguards of the constitution. Following the spirit of this rule, an individual member is never borne down in the exercise of his acknowledged privileges, though all the rest of the House may be against him, and may feel that he is only using them to their annoyance, and to the interruption of the public business. When the privilege of speaking is conceded, the duty of listening does not always follow. Members who are determined to speak when they have little to say worth hearing, or who continue to promulgate crotchets and hobbies in which their fellows have no sympathy, will empty the House, or even be made inaudible by the ebullitions of general impatience; but this never happens when a member, however little esteemed, has any important cause in his hands, or represents any considerable body of the people. On many occasions it has happened that the views or interests of a large portion of the population have had only one or two promulgators in the House of Commons; but these have hardly ever failed to command attention.

No bill is converted into a law unless it has received three readings—that is, has been at three stated intervals brought under consideration—in each House, has passed each House after the three readings, and has received the royal assent. There are some kinds of business peculiar to either House. The judicial function of Parliament is confined to the House of Lords, which alone has the inherent right to examine witnesses on oath. (See Appeal.) The supplies for the expense of conducting the business of the country are, on the other hand, exclusively the affair of the Commons. There are some kinds of legislation which it is the peculiar function of one of the Houses to originate. Measures affecting dignity and personal condition must, it is said, always begin in the Peers. All bills which affect taxes or duties, to the most trifling amount, can only begin with the Commons; and no peer's name must even be mentioned in them as connected with the raising of the duties.

Acts of Parliament are of two kinds, public and private. The former are laws which it is the judge's function to enforce, whether they are brought before him or not; the latter are like private deeds, which must be pleaded by those benefited by them ere the court is bound to give them effect. The bills, before they pass, are also divided into public and private. But it is important to remember that the difference between a public and private bill and a public and private act are not quite parallel. The acts, in fact, are of three kinds—*1st*, The public general statutes, which apply to the whole kingdom, or one of its departments; *2d*, The public local acts, such as police or railway acts; and *3d*, Private acts. It has been the practice, however, to speak of the second class of measures, which, when passed, would become public local acts, as private bills. There are three kinds of measures which in the House of Commons can only be brought in by committees of the whole House,—those affecting matters of religion, matters of trade, and the granting of money. The House does not always profess to know what was intended by these restrictions; but as an error in their application might vitiate a measure in any stage, a pretty wide interpretation is given to them. The Roman Catholic and Jews Relief bills, and a bill for punishing persons disturbing Roman Catholic congregations, were brought in by committee. It was decided in 1852 that a bill for establishing a registration of fees of ballast-heavers, with regulations as to the mode of hiring and paying them, is a bill relating to trade. It was found that a bill relating to dogs employed in drawing vehicles is not a measure of trade requiring to be brought in by committee.

The functions of Parliament in the passing of what are

Parliament

Forms of procedure.

termed private bills, according to the above definition, are peculiar and not easily explained. It has been said that they bear an analogy to the procedure in a court of justice; but they are in reality as distinct from these as they are from the proper functions of a legislature. In its purely public legislative capacity, Parliament enacts such laws as in its own knowledge it deems fit for the public, without waiting, so far as the proceedings bear, for any one to plead that they should be done, or any one to give evidence for or against them. In private business, Parliament lends its power for the fulfilment of objects desired by individual persons or by sections of the community, taking precautions for the assurance that such measures are just and proper. The promoters of a private bill appear as suitors for it, and may bring evidence and plead by council in its favour, as in a court of justice. Those who are opposed to it have the same privileges. So personal are the interests in a measure of this kind deemed, that when it is abandoned by its promoters it falls, however well it may have recommended itself as a just and useful measure to the good opinion of the legislature. "The solicitation of a bill in Parliament has been regarded by courts of equity so completely in the same light as an ordinary suit, that the promoters have been restrained by injunction from proceeding with a bill, the object of which was held to be to set aside a covenant; and parties have been restrained in the same manner from appearing against a private bill pending in the House of Lords. Such injunctions have been justified on the ground that they act upon the person of the suitor, and not upon the jurisdiction of Parliament." (May's *Parl. Proc.*, pp. 513-14.)

On the other hand, however, there are fundamental distinctions entirely separating the proceedings of Parliament in passing private bills from those of a court of justice proper. The litigant who goes to a court points to some established public law, and demands that it may be enforced in his favour. The promoter of a private bill goes to a body which is above the law, and asks a special law to be made for the accomplishment of his own objects, or even desires that the fixed course of law shall be suspended, and that he shall obtain something which the law expressly denies to him.

It is true, however, that, by applying uniform principles of action to the several groups of cases which the multiplicity of this kind of business has brought before them, the legislature has done all that perhaps could be done to give their procedure the uniform, undeviating tenor of judicial operations, and to circumscribe the extent of their own discretionary powers. They have brought into operation a large machinery of conditions which are absolutely necessary to the passing of a private bill, and which, consequently, in a great measure define the legal conditions under which a private bill to obtain any object can be carried through, as the law of the land prescribes the legal conditions under which the courts of justice will grant what the litigant asks. The greater part of this machinery is known as "the standing orders." They have of late been continually varied, through repeated efforts to bring them to perfection; and although they are now in a highly improved condition, it would be to no purpose to offer any statement of their purport suited for practical guidance, as they are liable to be altered every session; and the practitioner is never safe in taking any guide but the latest standing orders as issued by authority. The standing orders of the two Houses were formerly prepared without any reference to each other. They are now nearly, but not quite, identical; and the trouble caused by their partial divergence is greatly modified by a late arrangement, through which both Houses choose examiners to report on the compliance with the standing orders; and the same persons were selected for that duty by each House.

There are of course wide differences in the character and importance of private bills. One perhaps affects a population of half a million in matters so important as the local administration of justice, the organization of the police, and the paving, lighting, and sewering of the streets; while another is intended for the reconstruction of a bridge, the passing of the drainage from one private estate into another, or the sale of an entailed estate for public purposes. Hence, for the purpose of preparatory arrangements, the standing orders divide private bills into classes. The general objects of the standing orders are, notices to persons specially interested, advertisements to the public at large, plans, specifications, estimates, and deposits of money. In general, it is necessary that these injunctions should be carried out, and the way cleared for legislative proceedings in the coming session, before the end of December. About ten years ago an opinion was entertained that much of the legislative time devoted to investigations connected with private bills, and consequently much of the expense attending on them, might be saved by substituting preliminary inquiries under authorized officers for a portion of the evidence taken in Parliament. Accordingly, a system of preliminary inquiries was devised as a preparation for private bills in which public interests were concerned. In one large class of cases the inquiry was committed to the Board of Works, whose function it was to send a commissioner to the spot to hear evidence. Where the works to be authorized by the measure were likely to affect any tidal harbour, a similar function was confided to the Admiralty. The commissioners were to hear parties, summon witnesses, and call for plans and documents, like a court of justice. It must be presumed that this arrangement was found in some respects to be a failure, since in 1851 it was abolished in the class of bills for which the Board of Works acted, but was retained in those affecting the interests of the Admiralty.

Some general legislative measures, which may be divided into two different classes, have of late years had a very material effect in reducing the amount of private bill business which would have been necessary to carry into effect the arrangements to which they refer. One class of these acts contains provisions which are to be incorporated in particular classes of private bills. This device promotes uniformity, and by absolutely settling beforehand a certain portion at least of the measure which is to be discussed in Parliament, obviates a portion of the discussion, with the accompanying delay and expense. It seems to have suggested itself in one class of cases so early as the year 1801, when an act was passed containing clauses to be inserted in all subsequent inclosure acts. It does not seem, however, to have occurred to the legislature to extend this expedient to other classes of cases until a much later period. In the year 1845 several acts were passed, the object and function of which are explained by their titles, as, for instance, "An act for consolidating into one act certain provisions usually inserted in acts with respect to the constitution of companies incorporated for carrying on undertakings of a public nature;" "An act for consolidating in one act certain provisions usually inserted in acts authorizing the making of railways (8 and 9 Vic., caps. 16 and 20)." In this shape the legislature has, as it were, done once for all a certain proportion of its private bill legislation, affecting railways, canals, cemeteries, water supply, gas supply, and public companies generally. In 1847 an addition was made to this department of legislation by an act for the constitution and regulation of all bodies of commissioners appointed for public undertakings.

The other acts above alluded to as having abbreviated the amount of private bill legislation are of a different kind, since within their sphere they supersede legislation altogether, and organize another method of securing the objects

Parma.

in view. Here, too, the inclosure of land system seems to have pointed the way. In 1848 the passing of private bills containing certain assigned clauses, as already referred to, was superseded in this department, and a tribunal was appointed, called the Board of Commissioners of Inclosure, for definitively carrying out measures of inclosure. This method was applied, on a larger scale, in the creation of the Board of Health in 1848. The board, on certain requisitions, might institute a local inquiry in any town, and bring it within the provisions of the Public Health Act, which is a general embodiment of the sanitary department of a system of town police. The board was not absolute in the matter. The provisional orders which it issued were brought before Parliament in the ensuing session, and required to be confirmed by a general public act before they became law. In the session following that in which the board was established, an act was passed for the confirmation of such provisional orders applicable to fifteen towns in England.

There is a complex arrangement for the purpose of insuring impartiality in the appointment of committees to act on private bills. A committee of selection, consisting of five members, is appointed at the commencement of each session. It nominates a general committee on railway and canal bills. When the bill does not belong to either of these classes, the committee of selection chooses the committee who are to try it. The general committee on railway and canal bills choose the committees for trying these. The chairman is a member of the general committee; the number of members is five, and they must have no local connection with the measure. The Lords, in a manner nearly similar, select committees of five for the trial of opposed bills. Attendance is enforced, in order that none may judge without having heard the evidence; and the duties are often very arduous. It is now no longer practicable, as it used to be, for members of committee who had not heard the testimony or the pleadings, but who had some point of their own to carry, to rush in suddenly and swell a division. (J. H. B.)

PARMA, Duchy of, a state of Northern Italy, lying between N. Lat. 44. 19. and 45. 8., E. Long. 9. 23. and 10. 40. It is bounded on the N. by Austrian Italy, E. by the duchy of Modena, S. by Tuscany and the kingdom of Sardinia, and W. by the kingdom of Sardinia. Its length from E. to W. is about 50 miles; its breadth varies from 40 to 50; and its area is 2392 sq. miles. About a third of the country is mountainous, being occupied by the slopes and offsets of the Apennines; and several of the summits rise to a great height,—such as the Alpe di Succiso, 6807 feet high; Orsaio, 6180 feet, &c. The mountains are rugged and bleak, but their sides are covered with forests of chestnut, oak, ash, and beech. In the glens of the Apennines several affluents of the Po take their rise, and flow northwards, watering the lower regions. Most of these are small: the Tidone, Trebbia, Nura, Taro, and Parma are of some size, but none of them are navigable. Among the mountains lie many small lakes. The lowlands consist of fertile plains and hills. The most of the duchy belongs to the chalk formation, the loftier regions being entirely of this structure, while in the more level parts sandstone, calcareous tufa, and marls are also found. The mineral riches of the country are not very great: the principal is salt, of which there are several rich springs; iron is worked to some extent; copper in one place; and marble, alabaster, crystals, stones for lithography, &c., are obtained. The climate is generally temperate, and except near the Po, where unhealthy vapours prevail, salubrious. The people of the low country are chiefly employed in farming; and maize, wheat, pulse, tobacco, hemp, wine, and fruit are raised. Cattle of a good breed, sheep, poultry, silk, and bees are also produced. Large herds of hogs live in the forests; game of various kinds is plentiful; and the rivers abound in fish. The inhabitants of the mountains are, from the sterility of the soil, very inadequately supplied with food. They live chiefly on chestnuts, milk, and cheese. Many of them leave their homes in summer to seek employment in Lombardy or Tuscany; and large numbers annually emigrate to more distant countries. Parma contains few large manufactories; those of silk, which are the most important, exist in all the chief towns. Linen and cotton fabrics, paper, gunpowder, earthenware, and other articles, are likewise manufactured. The trade is not extensive, the principal articles imported being linen cloth, colonial produce, and articles of luxury; and the exports consisting of cattle, hogs, corn, wine, oil, &c. The government is an unlimited monarchy, hereditary in the male line. There are five superior courts; and the laws, established in 1820, resemble the Code Napoléon, with some modifications. The established religion is the Roman Catholic, to which most of the people belong; but toleration is extended to other sects. The duchy has primary schools, where the instruction is gratuitous; secondary schools; and superior academies at Parma and Piacenza. The military forces amounted in 1857 to 4130, which might be raised to 6139 in time of war. The revenue and the expenditure for 1857 were each estimated at L.381,332. The duchy is divided into five provinces. Pop. (1856) 495,840. In ancient times what now forms the duchy of Parma was a part of Gallia Cisalpina. After the fall of the Roman empire it was included in Lombardy; and Charlemagne, on conquering that kingdom, transferred Parma to the Papal See. In 1543 Paul III. conferred on his son Luigi Farnese the duchy of Parma and Piacenza. By the treaty of Aix-la-Chapelle in 1748, it was given to Philip, a son of Philip V. and Elizabeth Farnese. In 1801 Parma was conquered by Napoleon; but the Congress of Vienna decided that, after the death of the ex-Empress Maria Louisa, the duchy should fall to the Duke of Lucca. This took place in 1847, when Lucca was annexed to Tuscany.

Parma, the capital of the above duchy, stands in a beautiful plain, on the river of the same name, which is crossed by three bridges, 12 miles S. of the Po, and 72 S.W. of Milan. It is of an oval form, more than 4 miles in circumference, and is surrounded with walls and ditches. The streets are straight and regular, the principal being the old Roman Via Æmilia, running from E. to W. Many of the buildings are very handsome. The cathedral, consecrated in 1106, though in a mixed Lombard and Gothic style, is a noble edifice; and contains in the interior of its octagonal cupola a magnificent fresco by Coreggio, representing the Assumption of the Virgin. Parma contains one of the most splendid baptisteries in Italy, built of marble, and adorned with numerous paintings and statues. There are many other churches adorned with works of art, chiefly by Coreggio. The Farnese or ducal palace is an immense pile of building, and contains the great Farnese theatre, a library of 100,000 volumes, a picture gallery, and a museum of antiquities. Several of the other palaces of the nobility are fine buildings. The town has also an academy attended by about 400, an episcopal seminary, some inferior schools, a new theatre, and several charitable institutions. It is the residence of the duke, the see of a bishop, and the seat of the government and supreme court of law. There are here manufactories of silk, leather, carpets, cotton and woollen goods, paper, glass, earthenware, saltpetre, and other articles; and a ducal printing-press, which has issued some of the finest specimens of typography in Europe. Hardly any remains have been preserved of the ancient Parma, which occupied the same site. Pop. (1854) 41,091.

PARMENIDES, an eminent Greek philosopher of the Eleatic school, was born at Elea in Magna Græcia in the latter half of the sixth century B.C. The history of his education is not very well ascertained. Report speaks of two Pythagoreans, Ameinias and Diochætes, as his instructors. He is also said, with less verisimilitude, to have been a disciple of Xenophanes, the founder of the school of Elea. At all events, it is certain that he studied with great success, and rose to a high place in the estimation of his countrymen. He was honoured to be the instructor of Empedocles and Zeno; Plato surnamed him "the Great," and likened him to Homer; Aristotle considered him the chief of the Eleatics; and his own fellow-citizens were wont every year to swear obedience to a code of laws which he had laid down. The main philosophical opinions of Parmenides have come down to us in some fragments of a hexameter poem, entitled *On Nature*. They may be represented in the following short outline:—Assuming that sense and intellect are the only two sources of knowledge, he holds that these furnish the mind with two kinds of ideas entirely distinct. Sense is dependent on the variable organization of the individual; and therefore its evidence is changeable, false, and nothing else but a mere appearance. Intellect is the same in all individuals; and therefore its evidence is constant, true, and a complete reality. The subject is thus divided into two branches—physics and metaphysics; the former inquiring, What is the character of appearance? and the latter, What is the character of reality or being? Metaphysics, or the science of being, is discussed in the first of the two books of the poem. Being, it is asserted, is eternal. For if it be non-eternal, it must either have sprung out of being or non-being. It cannot have sprung out of being, since it cannot precede itself; and it cannot have sprung out of non-being, since non-being is utterly inconceivable. It is therefore eternal. Being is also identical with thought. For as it is eternal, it must be unchangeable, identical, unique, unity itself. Since it is unity, it must embrace all objects, and consequently all the thoughts that are occasioned by these objects. Being is therefore identical with thought. After the first book of the poem has thus evolved an ideal system of metaphysics, the second book proceeds to treat of the science of appearances or physics. A fanciful theory of the physical world is then laid down in accordance with the principles of the natural philosophy of that day. The most complete collection of the fragments of Parmenides is that of S. Karsten in the *Philosophorum Græcorum Veterum Operum Reliquiæ*, 8vo, Amsterdam, 1835.

PARMENIO, a distinguished Macedonian general, was born about 400 B.C. He had attained a mature age when he began to play a prominent part in the service of Philip of Macedon. At that time the king received him into his confidence as his favourite counsellor both in peace and war. Several important enterprises were also conducted by him in the course of the reign. In 356 B.C. he routed the Illyrians in a great battle; in 342 B.C. he successfully upheld, at the head of an army, the Macedonian influence in Eubœa; and in 336 B.C. he was appointed one of the commanders of the force that was sent to secure a footing in Asia, and to prepare for the future reduction of that country. Still greater was the importance of Parmenio after the death of Philip, and the accession of Alexander, in 336 B.C. At the council table the advice of the veteran general, though sometimes too tame for the wild genius of the young conqueror, was always heard with deference. In the field he was virtually second in command. He led on the left wing of the army at the battles of the Granicus, Issus, and Arbela; and he was entrusted with the important task of completing the subjugation of Media, while the king himself continued the pursuit of Darius into the wastes of Parthia and Hyrcania. This was the last appointment that Parmenio received. The faithful general, after he had grown gray in the service of Alexander and his father, and had lost two sons in this same expedition, was now to be rewarded with the most cruel ingratitude. His only surviving son Philotas, who had gone forward in the division of the army under Alexander, was arraigned for conspiring against the king's life. For lack of evidence, torture was applied; and a confession was wrung from him which implicated his father. Alexander, on this slight ground, and in a spirit of selfish policy, resolved to rid himself of Parmenio. Accordingly a message was despatched to Media; and the unsuspecting old man, while conversing with his officers, was stabbed by Cleander, in 330 B.C.

PARMIGIANO, or PARMIGIANINO, the name which Francesco Mazzuoli, the eminent painter, received from his native town of Parma. He was born in 1503; and being early left an orphan, he was brought up by two uncles who were painters. The boy soon began to show himself a prodigy of genius. While still a mere child, he astonished his writing-master by the sketches which he drew with his pen; in his sixteenth year, he painted the "Baptism of our Saviour" with all the skill and execution of a master; and before the age of twenty he had executed several public works, and risen to a high place in the profession. The style of Parmigiano, however, did not begin to be formed until, in 1523, he removed to Rome, and commenced to practise his art under the patronage of Pope Clement VII. The composition of his pictures then became grand and simple, the execution decided, the colouring well tempered, and the general effect full of the most exquisite grace. He was also characterized by a happy faculty of imitating Raphael, so that he acquired the surname of Il Raffaellino. Equipped with all these accomplishments, Parmigiano now executed some of those masterpieces which have immortalized his name. While still at Rome, he painted the "Vision of St Jerome," a picture which is now in the National Gallery. At Bologna, to which he repaired on the capture of Rome in 1527, he executed the figure of "St Rochus," still seen in the church of St Petronius in that city, and the Madonna della Rosa, now in the gallery of Dresden. On his return to Parma, that admired picture was painted which hangs at the present day in the Bridgewater Gallery, and represents Cupid fashioning his bow, while two boys sit at his feet, the one crying and the other laughing. From such great masterpieces Parmigiano would probably have proceeded to others still greater, and risen to rival Raphael and Michael Angelo, had not a fever cut short his career at Casal Maggiore in 1540. This painter was also eminent for his skill in etching.

PARNAHIBA, a town of Brazil, province of Piauhi, stands on the E. bank of the River Parnahiba, about 15 miles above its mouth, and 300 N. of Oeiras. It has broad unpaved streets. It is the only seaport in the province; but is not capable of admitting vessels of above 150 tons burden. Some trade is carried on in hides and cotton. The court-house and custom-house are the chief public buildings. Pop. of the district, about 10,000.

PARNAHIBA, a river of Brazil, rises near the 10th degree of S. Lat., and flows northward to the Atlantic, separating the provinces of Piauhi and Maranhão. Its whole length is more than 700 miles, for a great part of which it is navigable. It falls into the sea by several mouths, forming a delta about 5 miles broad. Its chief affluents are the Gorguea from the E., and the Balsas from the W.

PARNASSUS (modern *Liakura*), a mountain of Phocis, was celebrated in ancient mythology for its sacred character. Delphi, the oracle of Apollo, stood at its foot; the Corycian cave, sacred to Pan and the Nymphs, was situated on its slope; and Castalia, the stream which furnished the holy water for the Delphian temple, sprung up between its two summits. There also was the spot where

the Muses held their assemblies, and whence they took their flight through the midnight air.

PARNELL, Sir Henry, *Lord Congleton*, second son of Sir John Parnell, chancellor of the Irish exchequer, was born June 3, 1776, educated at Eton and at Cambridge, and afterwards travelled on the Continent. He first appeared in public life in 1802, when he sat for a few months as member of Parliament for Portarlington; but after the dissolution of Parliament he was not again a member until 1806, when he was returned for Queen's County, which he represented until 1832. During this period he was distinguished as a liberal and consistent Whig. His speeches were among the best of that period. Five of them he corrected for publication:—1*st*, On the "Irish Currency," in 1809; 2*d*, On "Tithes in Ireland," 1810; 3*d*, "The Bullion Report," in 1811; 4*th*, On the "State of Ireland," in 1824; 5*th*, On "Unlawful Societies in Ireland," in 1825. He was also the author of several interesting treatises or pamphlets, among which may be mentioned one on *Financial Reform*, in 1830, and a *Treatise on Roads*, which appeared in 1833. In 1830 a motion brought forward by him led to the dissolution of the Wellington cabinet; and he was chairman of the Finance Committee of the House of Commons in 1828. On the accession of his party to power, he was appointed one of the government commission to inquire into the excise laws, and became secretary at war, but resigned his appointments in 1832. In 1833 Sir Henry Parnell was returned to Parliament for Dundee, and for the same place in 1835, and again in 1837. On the formation of the Melbourne cabinet in 1835, he was appointed to the conjoined offices of paymaster of the forces and treasurer of the navy and ordnance, which he filled until the dissolution of that ministry in 1841, when he was called to the Upper House by the title of Baron Congleton of Congleton in Cheshire. In 1842 Lord Congleton's health became impaired; and, in a fit of temporary insanity, he put a period to his existence on 8th June in that year.

Parnell, *Thomas*, D.D., an elegant poet, was the son of an English landed proprietor who had emigrated to Ireland, and was born at Dublin in 1679. His progress through the several stages of his education was rapid. At the age of thirteen he entered the university of his native town; in 1700 he took the degree of M.A.; and in the same year, although under the canonical age, he was ordained a deacon. It was not, however, until after he had been appointed to the archdeaconry of Clogher, in 1705, that Parnell became known in the literary world. He then began to compose those poems which attracted attention by their easy versification, refined sentiment, and successful imitation of the manner of Pope. Escaping also from his solitary parsonage, he frequently visited London, to cultivate the friendship of the leading wits of both political parties. His generous heart, cultivated understanding, and social qualifications, made him a favourite with both Whigs and Tories. Addison and Steele admitted his papers into the *Spectator* and *Guardian*; and Pope, Gay, and Arbuthnot received him into the famous "Scriblerus Club." The closing years of the short career of Parnell were clouded with sorrow. The loss of his wife in 1712 inflicted a severe blow on his sensitive nature. His preferment, through the interest of Swift, to the vicarage of Finglass, in the diocese of Dublin, in 1716, did not relieve his melancholy. He became more and more averse to the solitude of home and the labours of the study, and more and more addicted to the excitement of London society and the oblivious influences of the bottle. These habits, it is said, undermined his constitution; and while returning to Ireland from a visit to the capital, he died at Chester in July 1718.

Parnell left behind him many compositions both in prose and verse. A selection from his poems, which has been frequently reprinted, was published after his death by Pope. Of these, *The Rise of Woman*, *The Fairy Tale*, *The Night-piece on Death*, and *The Allegory on Man*, deserve to be still remembered. But his most popular poem is *The Hermit*, a tale not more pleasing for its easy rhythm than for its novel plan and its picturesque incidents. A Life of Parnell, by Goldsmith, is published in Goldsmith's *Works*, in Murray's "British Classics."

PARNY, Evariste-Désiré Desforges, *Vicomte de*, the French Tibullus, was born in the island of Bourbon in 1753, and was sent to France to be educated at the age of nine. His devotion to literature did not appear in the early part of his life. At the college of Rennes he showed a listless dislike for the subjects of scholastic study. A spirit of religious fanaticism next possessed him, and led him to the very eve of entering upon a monastic life. Then rushing into the very opposite extreme of sentiment, he plunged into the midst of the pleasures of the world, enlisted in the army, and drank in with avidity the Epicurean maxims of the barracks. It was not until, at the age of twenty, he paid a visit to his native island, that an event occurred which awakened his poetical genius. He was there smitten with a passion for a young Creole maiden called Eleanor: she was soon after wedded to another; and the jilted lover returned disconsolate to France. His mind then resolved to vent its burden through the channel of verse. Accordingly, in a collection of elegies published in 1775 he described, with a fresh simplicity, easy grace, and deep pathos, the delights of a requited attachment, and the regrets, jealousies, and alternations between hope and fear, of a disprized love. The fair reputation which Parny gained by these poems was soon tarnished by a flagrant indiscretion. Losing all his fortune during the troublous days of the Revolution, and being driven to earn a livelihood by his own exertions, he was tempted to pander to the immoral tastes of the times. He commenced an attack upon decency and religion in his *Guerre des Dieux*; and he persisted in following up his odious attempt in his *Paradis Perdu* and *Galanteries de la Bible*. A piece on the culture of flowers, and another entitled *Journée Champêtre*, were almost the only productions of his latter years which were at the same time imbued with the genius of poetry and untainted by profaneness and obscenity. The consequence was, that the more respectable part of the community cherished towards him an aversion which had not passed away at the time of his death, in 1814. The select works of Parny were published by Didot, in 5 vols. 18mo, Paris, 1808, and reprinted in the *Collection de Classiques Français* of Lefevre, Paris, 1827. His *Poésies Inédites*, preceded by a notice on his life and works, were published by Tissot, 18mo, Paris, 1827.

PARODY (παρῳδία, literally *a song sung beside*,—*i.e.*, sung with certain changes, especially with the design of burlesquing the original) is a species of poetical pleasantry, produced by turning into ridicule what was intended for a serious composition. This humorous design is accomplished by preserving the form but changing the matter of the piece. This change of matter may be effected either directly or indirectly: directly, by the alteration of a letter, a word, or words, of the original, or by re-casting the whole piece, and at the same time preserving the peculiar style and form of the original; indirectly, by applying the original in its entirety, and without modification, to some subject quite foreign to the intention of the author. Parody is generally used in the same sense as *travestie*. The Greeks, from whom the word is borrowed, have the credit of originating this species of composition. Scholars assign the merit of the invention to Archilochus, but wrongly, if we are to regard the *Batrachomyomachia*, ascribed to Homer, as a species of parody. Perhaps the most successful Eng-

lish parodies of modern times are to be found in the well-known *Rejected Addresses* of the brothers Smith. *Punch* also occasionally furnishes a good parody.

PAROL is the Norman-French "word," and is employed in English law to denote oral as distinguished from written proceedings. Thus a parol contract is an agreement by word of mouth; parol evidence is the oral testimony of witnesses. In the strict acceptation of the term, however, everything is parol, even in writing, which is not under seal.

PAROLE, in a military sense, the promise (*parole d'honneur*) made by a prisoner of war, when he has leave of absence, to return at an appointed time, if not previously discharged.

PAROS, one of the largest of the islands of the Cyclades, is situated in the Ægean Sea, about 6 miles W. from Naxos, and consists of a circular mountain sloping down on all sides to a maritime plain. It was colonized at an early period by the Ionians. The island in course of time attained a high degree of prosperity. It planted colonies in Thasus (*Thaso*), at Parium on the Propontis, and at Pharos on the Illyrian coast. Its two harbours became the seats of an extensive maritime trade, and its chief town, Paros (*Parichia*), became a well-fortified city. It was strong enough to repel the attack of Miltiades by force, and wealthy enough to avert the attack of Themistocles by bribes. Shortly afterwards, however, Paros became tributary to Athens, and from that period it continued to be subject to those nations who held in succession the dominion of the Cyclades. It consequently lost all historical importance, and was chiefly famous for that beautiful Parian marble which was so extensively employed in the architecture and sculpture of the ancients. At the present time Paros belongs to the kingdom of Greece, and contains about 6000 inhabitants.

PARR, CATHARINE, Queen of England, was the eldest daughter of Sir Thomas Parr of Kendal Castle in Westmoreland, and was born at some date shortly before 1513. Her experience of the trials and vicissitudes of life began early. She was scarcely out of her childhood when her hand was given to Edward, Lord Borough of Gainsborough. Before a few years had passed, her husband died; and she became a widow in her fifteenth year. In a short time afterwards she was again married to John Neville, Lord Latimer; and at the age of twenty she was again left in solitary widowhood. It was this experience which assisted Catharine Parr in playing the difficult part which fell to her lot, when on the 12th July 1543 she was wedded to the royal wife-slayer Henry VIII. How prudently and successfully she played that part is described under ENGLAND. In 1547, the same year in which her husband the king died, Queen Catharine gave her hand to her former lover, Sir Thomas Seymour, lord-admiral of England. She died in child-bed in 1548, at the age of thirty-five.

PARR, *Samuel*, a very distinguished scholar and an acute thinker, was born at Harrow-on-the-Hill on the 15th of January 1747. At Easter 1752 he was admitted on the foundation of Harrow School, at that time conducted by the Rev. Dr Thackeray, and by the time he had attained the age of fourteen, he had, by his diligence and talents, gained the approbation of his successive teachers, and become the head boy of the school. In 1761 Parr, having completed the course of study pursued at Harrow, left school, and was for two or three subsequent years employed by his father in his own profession of apothecary and surgeon. He continued, however, to occupy all his leisure in the study of Greek and Roman literature; and his father, after considerable hesitation, entered him in 1765 at Emanuel College, Cambridge. Here his application to study was enthusiastic, incessant, and severe. His father's death, however, gave a temporary check to his hopes; and he was induced by Dr Sumner to accept of a first assistantship in Harrow school.

At Christmas 1769 Parr was ordained to the curacies of Willsden and Kingsbury in Middlesex, the duties of which, in conjunction with those proper to the situation which he held in the school, he continued to discharge till the death of Dr Sumner in 1771, when he opened a school on his own account at Stanmore. Not succeeding to his mind in this undertaking, he became master of Colchester school in 1777. During his residence there he took priest's orders, and his curacies were Hythe and Trinity Church. In 1778 he obtained the appointment of head-master of Norwich school, and early in 1779 entered upon the duties of his office. In the following year he published his two sermons *On the Truth and Usefulness of Christianity*, and *On the Education of the Poor*. He afterwards, in 1785, resumed the subject of the latter at great length in his *Discourse on Education, and on the Plans pursued in Charity Schools*. This was the most popular of all his writings, and is a fine monument of its gifted author's enlarged views, pure benevolence, and deep insight into human character.

In 1781 Parr took his degree of Doctor of Laws in the university of Cambridge, after supporting two theses, which were regarded as compositions of superior excellence and merit. In 1783 Bishop Lowth appointed him one of the prebends of St Paul's Cathedral; and during the same year he was presented to the perpetual curacy of Hatton, Warwickshire, to which, after resigning the school at Norwich, he went to reside in 1786. In 1787 appeared the justly-celebrated preface to Bellendenus, which, despite its fulsome flattery of Burke, North, and Fox, to whom it was dedicated, and its virulent political rancour, is undeniably one of the most successful modern imitations of Ciceronian Latin. But while this performance raised his fame, it did not add to his happiness, for it alienated friends, and made foes of those formerly indifferent. In 1790 Dr Parr got involved in an obscure and intricate controversy respecting the authorship of the *Bampton Lectures* published by Dr White, who seems, together with his coadjutors, to have been guilty of plagiarism.

The *Tracts by Warburton and a Warburtonian, not admitted into the collection of their respective works*, appeared in 1789, with a dedication addressed by the editor to a learned critic, containing some excellent critical remarks, and abounding at the same time in forcible expression and happy illustration. Of this composition, which it is to be feared was written more with the design of annoying Bishop Hurd, the editor of Warburton, than with any higher motive, Warton is reported to have said, that if he were called upon to point out some of the finest sentences in English prose, he would quote Parr's preface and dedication of the Warburtonian Tracts.

The Birmingham riots of 1791 called forth the *Sequel to the printed Paper lately circulated in Warwickshire by the Rev. Charles Curtis, brother of Alderman Curtis, a Birmingham Rector*, London, 1792; and *A Letter from Irenopolis to the Inhabitants of Eleutheropolis, or a Serious Address to the Dissenters of Birmingham;* both admirable specimens of the author's spirited and elegant style. In 1793 a violent pamphlet by Dr Combe occasioned *Remarks on the Statement of Dr Charles Combe, by an occasional writer in the British Critic*, 1795, written in a temporate, calm, and guarded tone. Parr's famous Spital Sermon of 1800 brought him into collision with Godwin and others of the opposite school of morals.

In 1802 Sir Francis Burdett presented him to the rectory of Graffham in Huntingdonshire. His last publication that is entitled to particular notice is, *Characters of the late Charles James Fox, selected, and in part written, by Philopatris Varvicensis*, which appeared in 1809. It con-

sists partly of extracts from the various public journals, and is partly of an original character, addressed in the form of an epistle to Mr Coke, with an additional volume of notes.

In 1823 Parr's strength began visibly to decline; and on the 6th of March 1825 he died, having completed the seventy-eighth year of his age. Notwithstanding his pre-eminent talents and great learning, Dr Parr left no work behind him destined to live. His natural benevolence and kindliness of feeling seems to have been too much cast into the shade by a vain, arrogant, and overbearing temper. When engaged in a polemic, as he too often was, he seemed actuated too much by a fierce party spirit, which led him not unfrequently to forget alike the claims of truth and the courtesies of controversy. He seems to have surpassed all men of his time in his uncommon powers of conversation. In addition to his published writings, Dr Parr left behind him a vast mass of papers, epistolary, historical, critical, and metaphysical. (See his *Works, with Memoirs of his Life and Writings, and a Selection from his Correspondence*, by John Johnstone, M.D., 8 vols. 8vo, London, 1828.)

PARRHASIUS, one of the most celebrated of Greek painters, was a native of Ephesus, and flourished towards the close of the fifth century B.C. Coming to Athens after he had studied under his father Evenor, he soon achieved the highest renown. The Athenians held him in great honour, and conferred upon him the privileges of a citizen. He painted many admirable pictures, which elicited from succeeding authors the most enthusiastic encomiums; and he established a canon of proportion which procured for him from Quintilian the title of "Legislator" of his art. How valuable his productions were, both in a practical and theoretical point of view, is described under the article PAINTING. There is even a story, that he foiled the great master Zeuxis in a contest of skill, in which he painted a curtain, and his rival painted a cluster of grapes. But while Parrhasius was thus proving himself to be one of the greatest of painters, he was also showing himself to be one of the weakest of men. He assumed the title of "Prince of Painters," and, in accordance with this character, exhibited himself to the citizens arrayed in purple and crowned with a golden garland. He dubbed himself Ἁβροδίαιτος ("The Elegant"); and he addressed to himself an epigram, dwelling with complacency upon his personal history, and congratulating himself for having brought painting to the very pitch of perfection. He had even higher moods of vanity, in which nothing less than a relationship with the immortals would satisfy him. Apollo was declared to be his ancestor, Hercules was said to visit him frequently in a vision of the night, and his own portrait was hung up in a temple to call forth adoration from the multitude. Two of the most celebrated works of Parrhasius were,—an allegorical representation of the Athenian people, which is said by Pliny to have indicated all the qualities, both good and bad, of the mob; and a picture of Theseus, which was afterwards removed to the Capitol at Rome.

PARRY, SIR WILLIAM EDWARD, *Knight*, the arctic navigator, was born at Bath, December 19, 1790. His father, Dr Caleb Hillier Parry, was a physician of considerable celebrity; his mother, the daughter of John Rigby, Esq., of Lancaster. The subject of this notice, their fourth son, had been originally intended for the medical profession, but circumstances occurred to alter this view; and in June 1803 he was appointed to the Ville de Paris, Admiral Cornwallis' flag-ship, of the Channel fleet, as a volunteer of the first class. He remained on board this ship for nearly three years, and was once engaged in action during this time off Brest harbour. Admiral Cornwallis thus recorded his opinion of the young sailor when he left his ship: —"Parry is a fine steady lad; I never knew any one so generally approved of. He will receive civility and kindness from all while he continues to conduct himself as he has done, which, I dare believe, will be as long as he lives." His next appointments were, successively, to the Tribune frigate, and Vanguard, 74. The latter was frequently engaged with Danish gunboats in the Baltic, on which occasions Parry commanded one of the Vanguard's boats.

Obtaining his lieutenant's commission in 1810, he joined the Alexandria frigate, in which vessel Parry made his first acquaintance with Polar ice between North Cape and Bear Island, after which he joined the La Hogue at Halifax. In 1814 he took part in a successful boat expedition up the River Connecticut, and was himself in command of one of the boats. For this service a medal was afterwards awarded. In 1817 he was recalled to England by his father's illness. He had for some time past almost despaired of promotion, when an opening unexpectedly occurred which threw a gleam of encouragement over his professional prospects, and finally proved the forerunner of success and renown. Towards the close of this same year he wrote to a friend on the subject of an expedition in contemplation for exploring the River Congo. The letter was written, but not posted, when his eye fell on a paragraph in the newspapers relative to an expedition about to be fitted out to the northern regions. He seized his pen, and added to his letter, by way of postscript, that, as far as he was concerned, "hot or cold was all one to him, Africa or the Pole." The friend to whom the letter was addressed showed it to Mr Barrow, secretary of the Admiralty, and the well-known patron of arctic discovery. In a few days, Parry, still a lieutenant, was appointed to the command of the Alexander discovery ship, under the orders of Commander John Ross in the Isabella, "for the purpose of exploring Baffin's Bay, and ascertaining the probabilities of a N.W. passage to the Pacific." This expedition, as is well known, ended in nothing. The ships entered Lancaster Sound, on the western side of Baffin's Bay; but the lively imagination of Ross conjured up a range of mountains barring all advance, and the ships returned home. The next year (1819), Lieutenant Parry, whose opinion as to the practicability of a N.W. passage had become known, was appointed to the command of the Hecla,—the Griper, Lieutenant Liddon, being also placed under his orders. Entering Lancaster Sound in the summer of 1819, Parry sailed *over* the supposed Croker Mountains of Ross, and naming, as he advanced, Barrow's Straits, Wellington Channel, and Melville Island, was compelled to winter at the latter place. The most difficult part of Parry's task now began. Hitherto, while the necessity of active exertion remained, and constant watchfulness of eye and hand were requisite in the prosecution of the dangerous voyage, it was comparatively easy for the commander of the expedition to preserve the health and cheerfulness of the crews. Now, however, it needed all the resources of a fertile mind and an active example to prevent the evil consequences likely to arise from want of regular employment during the dreary hours of a northern winter. But Parry was fully equal to the emergency. Theatrical entertainments were set on foot, Parry himself turning author for the time being; a weekly newspaper, the *North Georgian Gazette*, was started in the officers' mess-room; and every precaution taken to promote amusement and exercise among all. After ten months of confinement in Winter Harbour, the ships were set free; but the state of the ice rendering further progress to the westward hopeless, Parry was compelled to retrace his course to England. On his return, he was promoted to the rank of commander, was presented with the freedom of Bath and Norwich, and elected a member of the Royal Society. The narrative of this voyage to Melville Island was published by order of the Admiralty. "No one," it was said of this work at the time, "could rise from its perusal without being im-

pressed with the fullest conviction that Commander Parry's merits as an officer and scientific navigator are of the highest order; that his talents are not confined to his professional duties; but that the resources of his mind are equal to the most arduous situations, and fertile in expedients under every circumstance, however difficult, dangerous, or unexpected." (*Quarterly Review*, vol. xxv.)

In a scientific point of view, the results of this voyage are most important. On the subject of magnetism, especially, the observations, constantly and carefully registered, were the first which had ever been made so near the magnetic pole of the earth. No opportunity was ever omitted of gathering information which the means at hand could supply, and the exertions of the commander were ably seconded by those under him. The labours of Captain Sabine, R.A., who accompanied the expedition as astronomer, speak for themselves, being arranged in a valuable appendix to the narrative.

His second and third voyages, from 1821 to 1824, and from May 1824 to October 1825, respectively, were also undertaken with a view to the discovery of the long-sought N.W. passage. The former, on his return from which he was promoted to the rank of post-captain, and appointed hydrographer to the Admiralty, resulted in the discovery of the Straits of the Hecla and Griper. The voyage of 1824, resulting in the loss of the Fury, was the last expedition in which Parry was engaged for the discovery of a N.W. passage, his next public service having a different end in view, though it led him once more into similar scenes. Still, while the great problem remained unsolved, his own exertions had not been without brilliant results. To him we owe the passage of Lancaster Sound and Barrow's Strait; on the south and north, Prince Regent's Inlet and Wellington Channel; Melville Island and Banks' Land, to the far westward. Even his failures served as landmarks to guide the steps of those who followed in his track; and the extent of his success, on ground hitherto unexplored, had in a great measure exhausted the more difficult part of the undertaking, leaving to his successors only the glory of completing the last link in the chain of discovery. He lived just long enough to see this link added, as he felt sure would eventually be the case.

After the unsuccessful termination of the recent efforts to discover the N.W. passage, it seemed useless for the present to pursue the attempt further; but this did not hinder Parry from turning his attention to another quarter, where success seemed more hopeful. The interesting experiments which had been made during the late expeditions in the neighbourhood of the magnetic pole had induced many scientific men to speculate on the possibility of carrying out similar observations at the very pole of the earth itself. Parry employed the few leisure moments he could snatch from the duties of his office in drawing up a statement respecting the practicability of effecting this object by means of sledge-boats, as had been before proposed by his friend and brother officer Captain Franklin. Of the difficulties involved in the scheme he was fully aware; but, as he remarked in a letter to Franklin, then himself absent from England on arctic discovery, "The true reply to all doubts is, go and see!" The memorial, when completed, was laid before Lord Melville and the lords of the Admiralty, supported by a recommendation from Sir Humphry Davy, the president of the Royal Society, to whom Parry, as a member of the society, had communicated his views. As might be anticipated, some opposition was at first made to the scheme; but after further discussions, the objections were overruled, and Parry was appointed to the command of an expedition "for the purpose of attempting to reach the North Pole."

In March 1827 the Hecla left England. Treurenberg Bay, in the Isle of Spitzbergen, was the spot selected for her to remain in during the absence of the exploring party; and at 5 p.m. on the 21st of June, the two boats Enterprise and Endeavour, respectively commanded by Parry and his lieutenant, James C. Ross, bade farewell to their comrades on board the ship, and, with the usual salute of three hearty cheers, set out for the northward. The boats employed on this novel service were fitted with strong runners shod with smooth steel, in the manner of a sledge, to the forepart of which the ropes for dragging the boat were attached. The crew of each consisted of two officers and twelve men, of whom two were marines. The rough nature of the ice, combined with the softness of its upper surface, rendered each day's work very tedious and laborious. Urged on, however, by the example of their commander, the men, in spite of all these discouragements, laboured with the greatest cheerfulness and good-will. All hoped, and none more confidently than Parry himself, that the rugged ice over which they were now toiling would prove but the introduction to the smooth continuous plain of the main ice which the accounts of former navigators had led them to expect to the north of Spitzbergen. Day after day, however, went on, and no signs of improvement were visible for some distance to the northward, when it became by degrees painfully evident to both the commander and his officers that another obstacle to the completion of their purpose had unexpectedly arisen. This consisted in the southerly drift of the whole body of ice over which they were laboriously tracking their way, owing to the wind, which blew steadily from the N. or N.W. The observations carefully made at the close of each day's hard work showed too clearly that often less than half the distance travelled could be regarded as progress in a northerly direction. This mortifying truth was for some time kept from the knowledge of the men, who used, however, good humouredly to remark that they were "a long time getting to this 83°!" For a few days more they persevered in the face of heavy snow-storms and torrents of rain, which Parry had never seen equalled, but the drift of the ice continuing as great as ever, he was at length compelled to confess that further labour was useless. It was now the 27th of July; the day was warm and pleasant, forming a cheerful contrast to the weather they had lately experienced. "Our ensigns and pendants," Parry writes, "were displayed during the day, and sincerely as we regretted not having been able to hoist the British flag in the highest latitude to which we had aspired, we shall perhaps be excused having felt some little pride in being the bearers of it to a parallel considerably beyond that mentioned in any well-authenticated record." The southward journey over the ice occupied a fortnight; and on the 28th August the Hecla weighed anchor for England. On the 1st November she was paid off, when, for the last time, Parry hauled down his pendant. "No successor on the path of arctic adventure has yet snatched the chaplet from the brow of this great navigator. Parry is still the champion of the North." (*Times*, January 20, 1856.) At this day, through the graceful compliment of recent navigators, the land nearest either pole on which the eye of civilized man has ever rested, bears the name of him who unfurled his country's flag at a higher latitude than any before or since have been able to reach: 82° 45′ was the latitude attained on this occasion. The Parry Mountains were discovered by Sir J. C. Ross in the antarctic regions in 1841; and the same name was given by Dr Kane in 1853 to a mountain visible to the N. of Smith Sound.

His next appointment led him into far different scenes. In consequence of the mismanagement and neglect of the agents resident on the property of the Australian Agricultural Company, the directors had for some time been anxious to secure the services of some one of sufficient ability to restore matters to a proper footing, and whose known

character and name would at the same time be a guarantee against the evils from which they had before suffered. With these views, they offered the post to Captain (now Sir Edward) Parry, for he and Franklin had, on the 29th of April 1829, received the honour of knighthood at the hands of his Majesty George IV. All professional difficulties were over-ruled by the kind assurance of Lord Melville, that his acceptance of the company's offer should in no way interfere with his future prospects. Accordingly, in the spring of 1829, he received his appointment as commissioner of the Australian Agricultural Company in New South Wales. Residing at Port Stephens, the neglected state of the settlement called for the exercise of all his energies. It was, in truth, to use his own words, "a moral wilderness;" and to the cultivation of this unpromising soil he and his wife resolved to apply all their energies. The people around them consisted of three distinct classes,—First, The officers and servants of the company; secondly, The convicts, working also in the employ of the company, or acting as domestic servants in the officers' families, that of the commissioner himself included; and lastly, The natives, whose home was in the "bush," and whose encampments were often found within a few yards of the settlement. He fitted up a carpenter's shop as a place of worship, conducting the service himself, and regarding nothing as too trivial, whether a cricket-match or a *fête*, which could tend to promote innocent enjoyment, and draw close the bond which united him to those under his charge. The task of reformation proved, indeed, no easy one. The almost total want of proper discipline which had previously existed in the settlement rendered it a matter of no small difficulty to introduce a new system of order and regularity. This, however, Parry was determined to effect; and though there was at the outset much to dishearten, his judgment and firmness by degrees triumphed over all obstacles, while the genial kindness of his disposition, and his evident desire for the general welfare, gained the respect and affection of all. The want of a regular church and minister becoming more and more felt each day, he felt, as the time for his departure approached, that he could not leave a better legacy to those over whose interests he had watched for four years than a building consecrated to the service of Him whose glory had been his constant aim. A site was accordingly determined upon at Stroud. Monday, April 29, 1833, was a day long remembered in the colony, when the first stone of the new church was laid by Sir Edward. "At Port Stephens," wrote one who visited that place some years later, "Sir E. Parry found a wilderness, but left a land of hope and promise." On his return to England in 1835, the directors of the Australian Agricultural Company invited him to a public dinner, and presented him with a handsome service of plate, "in testimony of the high sense entertained of the benefits conferred by him on the colony during his residence there."

Returning to England in 1835, Sir Edward was appointed assistant-commissioner of poor-law in the county of Norfolk. The act of 1834, passed to remedy the abuses which existed under the old poor-law administration, rendered the duties of the situation arduous and often very unpleasant, by bringing him into contact with those who were unwilling to acquiesce in the new order of things. His health shortly became impaired under the pressure of work, and after a year and a half he was compelled to tender his resignation. In accepting his resignation, the commissioners expressed their regret, "on their own account personally, but still more on account of the loss of his public services, the value of which they had learnt fully to appreciate from the many proofs they had received of the discreet, judicious, and efficient manner in which he had conducted his operations in Norfolk."

In February 1837 Sir Edward was employed for a short time by the Admiralty in the organization of the packet service between the Liverpool, Holyhead, and Dublin stations. His health was now so far improved that he was anxious to be once more actively employed. An opportunity soon presented itself. The introduction of steam-power into the navy had by that time wrought great changes in the service, and a new department being about this time formed at the Admiralty, the superintendence was offered to, and accepted by, Sir Edward, under the title of "Comptroller of Steam Machinery." For nearly nine years he held the post, which proved no sinecure. The duties of his office, at first sufficiently arduous, became each day more laborious During the time of his appointment as comptroller of steam machinery the application of steam-power in the navy became almost universal. Among the most important improvements effected was the introduction of the screw-propeller, now justly regarded as indispensable in every man-of-war. Those who took an interest in this invention, and were, consequently, able to form a judgment on the subject, acknowledge that its success in the Royal Navy (which led to its general adoption in the merchant service) was, in no small degree, owing to Sir Edward's constant and earnest advocacy. Certainly few were more sanguine in their expectations of its ultimate success, and none more energetic in the support of its claims at the Admiralty. In the autumn of 1841 he was employed by Sir Robert Peel's government in drawing up a report on the state of the Caledonian Canal, and the advantage which might result from opening its waters to larger vessels. The report drawn up by him after this survey resulted in the completion of the Caledonian Canal, which was re-opened in April 1847, and has been in operation since that time, with all the advantages of increased depth of water, and other accommodation for the transit of larger vessels. In December 1846 he received from Lord Auckland (first lord of the Admiralty) the appointment to the post of captain-superintendent of the Royal Clarence Yard and of the Naval Hospital at Haslar. The position was one in every way congenial to his tastes, as bringing him once more into immediate connection with members of his own profession. As might be supposed from his life at Port Stephens, he took an active interest in the spiritual, no less than the temporal, welfare of the patients in the hospital. With the exception of the lunatics, to whom one wing of the establishment was devoted, the same individuals seldom remained under his control for many weeks together, but the number of patients actually within the walls at one time amounted to several hundreds. Desirous of providing these with an opportunity of religious instruction, independently of the regular services conducted by the chaplain, Sir Edward, on the second or third Sunday after his arrival at Haslar, commenced, with the chaplain's consent, a series of Sunday evening lectures, which were continued during the whole time of his command. These were always well attended, upwards of a hundred patients being sometimes present. "In such repute," says a medical officer of the hospital, "were these lectures held, that numerous visitors found their way to the officers' houses in order to have the satisfaction of attending them." The organization of the dockyard battalions was first commenced during the time of Sir Edward's command at Haslar; and the labourers and artisans employed in the Clarence Yard were formed into a separate corps, of which he received his commission as colonel-commandant. While at Haslar, Sir Edward gave his full support to the different religious societies of which he was a member. At Gosport and Portsea he was continually called upon to take the chair at their provincial meetings. At the time of the well-known papal aggression in 1850 a meeting was held at Gosport for the purpose of presenting an address to her Majesty; and the resolution embodying the proposed address was moved by Sir E. Parry in an energetic speech

expressive of his own willingness to take a foremost place in resisting a movement which he felt to be opposed to "the Protestant throne, the Protestant liberties, and, above all, the Protestant faith of his country."

In the foundation of a Sailor's Home at Portsmouth Sir Edward took an active part. Of the great importance and value of these institutions he was fully convinced, and always condemned in the strongest terms the idea entertained by not a few naval officers, that the character of British seamen would be lowered in the eyes of the world by any attempts to improve their moral and social condition on shore.

In May 1852 he reached his rear-admiral's flag, and was therefore obliged to vacate his post at Haslar; but towards the close of the following year he was appointed by Lord Aberdeen to the lieutenant-governorship of Greenwich Hospital. A lecture to seamen, delivered about this time at Southampton, has since been published, and placed in the seamen's libraries of her Majesty's ships by order of the Admiralty. In the summer of 1854 London and its suburbs were severely visited with Asiatic cholera. In the hospital itself it found its victims, though its ravages there were not so great as in the surrounding localities. Towards the end of August Sir Edward was himself attacked with the premonitory symptoms, which, though soon brought under control, seemed to be the exciting cause of his suffering and fatal disorder. The malady soon evidently gained ground instead of decreasing; and in order to leave no means of alleviation untried, it was determined to remove him to Ems, for the benefit of the advice of a celebrated German doctor. The hopes of recovery at first held out soon proved delusive, and he died on the 8th of July 1855.

The remains were brought to England, and buried in the mausoleum of Greenwich Hospital. Sir Edward Parry was twice married: his first wife was a daughter of Sir John Stanley, afterwards Lord Stanley of Alderley; the second, Mrs Samuel Hoare junior, daughter of the Rev. R. Hankinson.

Besides the lecture to seamen above mentioned, and the narratives of his four polar voyages, Sir Edward Parry wrote a small volume—*The Parental Character of God.* (See *Memoirs of Rear-Admiral Sir W. E. Parry, Knt., F.R.S., &c.*, by his son the Rev. E. Parry, M.A., London, 1857.) (E. P.)

PARSON AND VICAR, in the Church of England. A parson (*persona ecclesiæ*) is, according to Blackstone, one who has full possession of all the rights of a parochial church. He is called parson (*persona*), because by his person the church, which is an invisible body, is represented; and he is in himself a body corporate, in order to protect and defend the rights of the church, which he personates, by a perpetual succession. He is sometimes called the *rector* or governor of the church; but the appellation of *parson*, however it may be depreciated by familiar and indiscriminate use, is the most legal and most honourable title that a parish priest can enjoy; because such a one, as Sir Edward Coke observes, and he alone, is said *vicem seu personam ecclesiæ gerere.* A parson has during his life the freehold in himself of the parsonage-house, the glebe, the tithes, and other dues. But these are sometimes appropriated; that is to say, the benefice is perpetually annexed to some spiritual corporation, either sole or aggregate. The appropriating corporations, or religious houses, were wont to depute one of their own body to perform divine service, and administer the sacraments, in those parishes of which the society was thus the parson. This officiating minister was in reality no more than a curate, deputy, or vicegerent of the appropriator, and was therefore called *vicarius*, or vicar. His stipend was at the discretion of the appropriator, who was, however, bound of common right to find somebody, *qui illi de temporalibus, episcopo de spiritualibus, debeat respondere.* But this was done in so scandalous a manner, and the parishes suffered so much by the neglect of the appropriators, that the legislature was forced to interpose; and accordingly it was enacted, by statute 15 Richard II., c. 6, that in all appropriations of churches the diocesan bishop should ordain, in proportion to the value of the church, a competent sum to be distributed amongst the poor parishioners annually, and to provide that the vicarage should be sufficiently endowed. It seems that the parish were frequent sufferers, not only by the want of divine service, but also by the withholding of those alms for which, amongst other purposes, the payment of tithes was originally imposed; and therefore in this act a pension was directed to be distributed amongst the poor parochians, as well as a sufficient stipend to the vicar. But he, being liable to be removed at the pleasure of the appropriator, was not likely to insist too rigidly upon the legal sufficiency of the stipend; and therefore, by statute 4 Henry IV., c. 12, it was ordained that the vicar should be a secular person, not a member of any religious house; that he should be vicar perpetual, not removeable at the caprice of the monastery; and that he should be canonically instituted and inducted, and be sufficiently endowed, at the discretion of the ordinary, to do divine service, to inform the people, and to show hospitality. In consequence of these statutes, the endowments were usually by a portion of the glebe, or land belonging to the parsonage, and a particular share of the tithes, which the appropriators found it most troublesome to collect, and which were therefore generally called *petty* or *small tithes;* the greater, or predial tithes, being reserved for their own use. But owing to the unsatisfactory footing on which tithes stood in the year 1836, by 6 and 7 Will. IV., c. 71, and succeeding statutes, "The Tithe Commissioners of England and Wales" were empowered to commute the tithes into a rent charge adjusted to the average price of corn.

The distinction between a parson and vicar is this:—The parson has for the most part the whole right to all the ecclesiastical dues in his parish; but a vicar has generally an appropriator over him, who is entitled to the best part of the profits, and to whom he is in effect perpetual curate, with a standing salary. The method of becoming a parson or vicar is much the same. To both there are four necessary requisites,—holy orders, presentation, institution, and induction. (See BENEFICE.)

PARSONSTOWN, or BIRR, a market-town of Ireland, in King's County, stands on a gentle slope near the Little Brosna, 22 miles S.W. of Tullamore, and 69 W.S.W. of Dublin. It is separated into two parts by the Birr, a small affluent of the Little Brosna; and it consists of one chief and several smaller streets. They are generally straight and clean, and are lined with well-built stone houses. At one end of the principal street is a handsome square, containing a column and statue of the Duke of Cumberland, erected in 1747 to commemorate the battle of Culloden. The parish church, built in 1815, is a fine Gothic edifice with a square tower. The only other remarkable building is a Roman Catholic church surmounted with a lofty spire. There are several other places of worship, a court-house, several schools, a reading-room, public library, savings-bank, dispensary, fever hospital, workhouse, and bridewell. In Parsonstown and its vicinity there are flour and rape mills, linen factories, breweries, and distilleries. Corn markets are held weekly, and fairs quarterly. The trade, however, is of little importance. Close upon the town stands Birr Castle, the seat of the Earl of Rosse. It is a fine castellated and embattled building of great antiquity; but it has been considerably modernized. In the lawn in front of the castle Lord Rosse's great telescope has been set up. Pop. (1852) 5540.

PARTHENON. See ATHENS, and ARCHITECTURE.

PARTHIA, a celebrated empire of antiquity, was bounded on the W. by Media, on the N. by Hyrcania, on the E. by Aria, and on the S. by Caramania and Persis. It was surrounded on every side by mountains or deserts, and its surface was hilly and rugged. According to Ptolemy, Parthia was divided into five districts,—Camisene, Parthyene, Choarene, Apavarctene, and Tabiene. The ancient geographers enumerate a great many cities in this country; Ptolemy, in particular, reckons twenty-five large ones; and it must have been very populous, since we have accounts of two thousand villages, besides several cities, which were destroyed by earthquakes. Its capital was named *Hecatompolis*, so called from the circumstance of its having a hundred gates.

The history of the ancient Parthians is involved in obscurity. All we know about them is, that they were first subject to the Medes, then to the Persians, and lastly to Alexander. After the death of the Macedonian conqueror, the province fell to Seleucus Nicator, and was held by him and his successors till the reign of Antiochus Theus, about two centuries and a half B.C. At this time the Parthians revolted, and chose Arsaces as their king. Seleucus Callinicus, the successor of Antiochus Theus, attempted to reduce Arsaces; but the latter having had time to strengthen himself, defeated his antagonist, and drove him out of the country. In a short time, however, Seleucus undertook another expedition against Arsaces, which proved still more unfortunate than the former; for being defeated in a great battle, he was taken prisoner, and died in captivity. Arsaces being thus established in his new kingdom, reduced Hyrcania and several other provinces; but he was at last killed in a battle against Ariarathes, King of Cappadocia. From this prince all the other kings of Parthia took the surname of *Arsaces*, as those of Egypt did that of *Ptolemy* from Ptolemy Soter.

Arsaces was succeeded by his son, who, having entered Media, made himself master of that country whilst Antiochus the Great was engaged in war with Ptolemy Euergetes, King of Egypt. Antiochus, however, had no sooner found himself disengaged from that war, than he marched with all his forces against Arsaces, and at first drove him completely out of Media. But the latter soon returned with an army of 100,000 foot and 20,000 horse, with which he put a stop to the progress of Antiochus; and a treaty was soon afterwards concluded, by which it was agreed that Arsaces should remain master of Parthia and Hyrcania, upon condition of assisting Antiochus in his wars with other nations.

Arsaces II. was succeeded by his son Priapatius, who reigned fifteen years, and left three sons,—Phraates, Mithridates, and Artabanus. Phraates, the elder, succeeded to the throne, and reduced the Mardians, who had never been conquered by any but Alexander. His brother Mithridates, who was next invested with the regal dignity, reduced the Bactrians, Medes, Persians, and Elymeans, and overran a great part of the East, penetrating beyond the boundaries of Alexander's conquests. Demetrius Nicator, who then reigned in Syria, endeavoured to recover these provinces; but his army was entirely destroyed, and he himself taken prisoner, in which state he remained till his death. After this victory, Mithridates made himself master of Babylonia and Mesopotamia; so that all the provinces between the Euphrates and the Ganges were now subject to his sway.

Mithridates died in the thirty-seventh year of his reign, between 138 and 130 B.C., leaving the throne to his son Phraates II. But the latter was scarcely settled in his kingdom, when Antiochus Sidetes marched against him at the head of a numerous army, on the pretence of delivering his brother Demetrius, who was still detained in captivity. Phraates was defeated in three pitched battles, in which he lost all the countries conquered by his father, and was reduced within the limits of the ancient Parthian kingdom. Antiochus, however, did not long enjoy his good fortune. His numerous army being obliged to scatter themselves over the country, were attacked at disadvantage by the inhabitants, and all the invaders, along with their monarch, were exterminated. Phraates, elated with this success, proposed to invade Syria; but happening to quarrel with the Scythians, he was cut off, with his whole army, by that people.

Phraates was succeeded by his uncle Artabanus. The new king, however, enjoyed his dignity for a very short time, being, a few days after his accession, killed in another battle with the Scythians. He was succeeded by Pacorus, who entered into an alliance with the Romans. Who was the next occupant of the throne has not been ascertained; but the next king whose reign is authenticated was Sanatroces. He died about 70 B.C., after a reign of seven years, and was succeeded by Phraates III. This monarch took under his protection Tigranes, the son of Tigranes the Great, King of Armenia, gave the young prince his daughter in marriage, and invaded the kingdom with a design to place him on the throne of Armenia; but he soon thought proper to retire, and to remain at peace with the Romans. Phraates was murdered by his children Mithridates and Orodes; and soon afterwards the former was put to death by his brother, who thus became the sole master of the Parthian empire.

In this reign happened the ever-memorable war with the Romans under Crassus. It had its origin in the spirit of rivalry which existed between the triumvirs who then presided over the destinies of Rome. Pompey had conquered Mithridates and the pirates; Cæsar had subdued Gaul; and Crassus felt the necessity of maintaining his position by the achievement of some military exploit. Accordingly, no sooner had he been elected consul in 55 B.C., and obtained Syria for his province, than he resolved to invade Parthia. This expedition, owing to the fact that it was directed against a friendly people, met with considerable opposition at its very outset. The Senate refused to sanction it. The presence of Pompey was required to save it from an attack of popular dissatisfaction as it passed through the streets of Rome. When it issued from the city, the tribune Ateius, posted at the gate, with strange and awful incantations and anathemas, devoted it and its leader to perdition. Nevertheless, Crassus persisted in his enterprise. He marched to Brundusium, and sailed to Macedonia. Continuing his route through Macedonia and Thrace, across the Hellespont, and through Galatia and the northern part of Syria, he crossed the Euphrates, and commenced hostilities. Yet scarcely had a few towns yielded to the Roman arms, than that imprudence of Crassus which led to the ruin of the expedition began to manifest itself. Instead of following up his success, pressing onwards, and attacking the enemy unprepared, he returned to Syria, and passed the winter in inactivity. It was not deemed necessary to collect information and to provide resources for the coming campaign. The soldiers were allowed to neglect their training and discipline. He himself spent his time in inquiring into the revenues of cities and weighing gold in the temple of Hierapolis. This infatuation reached a climax when the time for taking the field again, and advancing into the heart of Parthia, arrived. In vain did his ally Artavasdes, King of Armenia, advise him to direct his route along the chain of the Armenian mountains, where his march might be safe from the attacks of the enemy's cavalry. In vain did the quæstor, the famous Caius Cassius, suggest to him the expediency of marching along by the side of the Euphrates, where the army might be supplied with provisions from the ships. His ear was given unreservedly to an Arab chief, who pro-

fessed the most devoted fidelity to the Romans, but who had come expressly to betray them into the hands of the Parthian king. By the advice of this smooth-tongued barbarian, he resolved to advance right through Mesopotamia. A series of disasters, unsurpassed in ancient history for their tragic interest, was the result. The army had not advanced far before they found themselves in the midst of a waste sandy plain stretching away on all sides to the horizon. There were no trees to shield them from the burning sun, no herbs to supply fodder for their horses, no streams to slake their parched throats. Want and destruction seemed to be closing around them. At this juncture they received intelligence that the foe was at hand. Then there rushed upon their minds the reports they had formerly heard of those formidable Parthian horsemen who were clothed in impenetrable mail, who drove their arrows sheer through the shields and breast-plates of their enemies, and who, while fleeing, turned round upon their saddles and shot down their pursuers with deadly certainty. Their courage began to falter. Crassus himself was so paralysed with terror that he was at a loss how to arrange his forces for the coming onset. At first he extended them in a long line, to prevent them from being surrounded. Then he formed them into a solid square, flanked by squadrons of cavalry. In this order they were hurried on over the toilsome desert until they came in sight of the Parthians under the command of Surenas. The Parthian army appeared to be neither large nor well-equipped. But no sooner had the signal for battle been given, than up from its rear, as if from the bosom of the earth, sprung battalion after battalion of barbarian soldiers. At the same instant their coats of skin, which had aided in concealing them from the eye, were dropped off, and they stood under the summer sun a living mass of glittering steel. The order to advance was passed, and on they came, marching to the crash of kettle-drums, and exasperating their valour to the pitch of frenzy with savage yells and bellowings. With a well-directed flight of arrows, they drove the advancing battalions of the invaders back into the ranks of their densely-crowded square. Then, surrounding that mass of living beings, they began to pour in upon it a continuous shower of deadly shafts. At first the Romans expected that their assailants would lay aside their bows, and come to a hand-to-hand engagement. They therefore stood passively for a while under the winged destruction which fell upon them. When they perceived, however, that there were camel-loads of arrows, furnishing a continual supply to the quivers of the archers, their strained patience gave way. A part of the army under young Crassus charged out upon their foes, and finding that they retreated, pursued them at full speed. Yet no sooner had the Parthians drawn their pursuers to some distance away from the main body of the Roman army, than wheeling suddenly round under concealment of a cloud of dust, they caught them completely off their guard. Cutting off their retreat, and hemming them in on all sides, they brought them to bay upon a small eminence, and showered in arrows upon them till not a man was left. Then they returned with redoubled valour, and with loud shouts of victory, to renew their onslaught upon the main body of the invading army. Their heavy cavalry drove in and compressed the enemy's square with their pikes, as their light cavalry thinned it with their arrows. The approach of darkness alone put a stop to their destructive attacks. As the diminished numbers of the Romans encamped that night among their dead, they were in great perplexity about their impending fate. Crassus lay prostrate upon the earth in the stupor of despair, and could take no measures for the common safety. It became the duty of the quæstor Cassius and the lieutenant Octavius to call a council of war. The resolution was adopted of escaping immediately while the enemy was at a distance passing the night. Leaving the wounded behind to bewail their fate, they hastened away with all possible speed, and arrived at Carhæ (the *Haran* of the Bible) before they could be overtaken. The ill-fated Romans, however, were still within the toils of their artful enemy. When they would have tarried within the town for reinforcements from Armenia, they found their Parthian pursuers encamped before the walls, and ready to commence an assault. When they determined to depart from the city by night, and continue their retreat, a citizen named Andromachus plotted their destruction. He first informed Surenas of their intention. Then undertaking to guide them in their flight, he retarded their escape by leading them in a zig-zag course, and completed their bewilderment by landing them in a morass. Cassius, indeed, disentangled himself from this snare, and, at the head of five hundred horse, found his way to Syria. But day came, and showed Crassus with four cohorts still floundering in the swamp, and the Parthians close at hand. He had only time to get out of the marshes, and to station his troops on a height, when the enemy came up. Surenas now saw reason for changing his tactics. A range of mountains was near; the least delay might allow the Romans to escape thither, and there they would be secure from the onset of the Parthian cavalry. He resolved to try stratagem. Advancing from among his men to the foot of the height, with bow unbent and hand outstretched, he invited the Roman general to a peaceful conference. In obedience to the clamorous demand of his troops, Crassus went down the hill with a few attendants. "What!" exclaimed the wily barbarian; "a Roman general on foot! Let a horse be brought." A richly-caparisoned steed was led up. A significant glance from Surenas informed the Parthian attendants what they were to do. They lifted Crassus roughly on to the saddle, and began to hurry him away. The Romans who had come along with him interfered; a scuffle ensued; and the unfortunate triumvir was slain. The triumph of the Parthians was now easily completed. A part of the Romans surrendered; those who attempted to escape were pursued and cut to pieces; and King Orodes celebrated the victory by ordering molten gold to be poured into the mouth of Crassus, in mockery of the avarice of the deceased.

But Surenas did not long enjoy the pleasure of his victory; for Orodes, jealous of his power and authority amongst the Parthians, soon afterwards caused him to be put to death. Pacorus, the king's favourite son, was placed at the head of the army, and, agreeably to his father's directions, invaded Syria; but he was driven back with great loss by Cicero and by Cassius, the only general who had survived the defeat of Crassus. After this no mention is made of the Parthians till the time of the civil war between Cæsar and Pompey, when the latter sent ambassadors to solicit succour against his rivals. This Orodes was willing to grant, upon condition that Syria should be delivered up to him; but as Pompey would not consent to such a proposal, the succours were denied.

Cæsar is said to have meditated a war against the Parthians, which in all probability would have proved fatal to them. His death delivered them from this danger. But not long afterwards the eastern provinces of the Roman empire being grievously oppressed by Mark Antony, rose in arms, and invited the Parthians to join them. The latter readily accepted the invitation; and in 40 B.C. crossed the Euphrates under the command of Pacorus and Labienus, a Roman general of Pompey's party. At first they met with great success, and overran all Asia Minor, reducing the countries as far as the Hellespont and the Ægean Sea, and likewise subduing Phœnicia, Syria, and even Judea. They did not, however, long enjoy their new conquests; for, being elated with their victories, and despising

the enemy, they engaged Ventidius, Antony's lieutenant, before they had effected a junction with the forces under Labienus, and sustained a complete defeat. This so disheartened Labienus that he abandoned his men by night, and left them to be cut to pieces. Ventidius, pursuing his advantage, gained several other victories, and at last entirely defeated the Parthian army under Pacorus, slaughtering almost the whole of them, and the prince himself among the rest. He did not, however, pursue this victory as he might have done, being afraid of giving umbrage to Antony, who had already become jealous of the great honour gained by his lieutenant. He therefore contented himself with reducing those places in Syria and Phœnicia which the Parthians had taken in the beginning of the war, until Antony arrived to take the command of the army upon himself.

Orodes was almost distracted with grief on receiving the dreadful news of the loss of his army, and the death of his favourite son. When time had restored the use of his faculties, he appointed Phraates, the eldest but the most wicked of all his children, to be his colleague and successor. Phraates commenced his reign by murdering his father, his thirty brothers, and all the rest of the royal family. He did not even spare his own eldest son, lest the discontented Parthians should place him, as he was already of age, upon the throne. Many of the chief lords of Parthia, intimidated by the cruelty of the new king, retired into foreign countries. One of these, Monœses, a person of great distinction, having fled to Antony, arrived in time to aid the Roman general in planning an expedition against the Parthians. Accordingly Antony set out on his march towards the Euphrates in 36 B.C., at the head of an army of 100,000. On his arrival at the river, he found all the defiles so well guarded that he deemed it expedient to enter Media, with a design first to reduce that country, and then to penetrate into Parthia. Leaving his battering-engines to follow in the rear under the protection of two legions, he advanced by forced marches to the Median city of Praaspa or Phraata, and immediately invested it. But a long series of disasters now began to thwart the object of his enterprise. The convoy in charge of his storming-machines was attacked and cut to pieces before it could reach the place of its destination. His beleaguering forces continued to blockade the town without any success, until the growing desolation of the surrounding country, and the coming severity of winter, warned them to repair to some more hospitable clime. He then exchanged the toils of an unsuccessful siege only for the disasters of an inglorious retreat. During his march homewards, the redoubted Parthian cavalry hovered round the army, laying waste the country in front, harassing the rear, and intercepting supplies. Several defeats which he gave them did not check their pertinacity. They continued their flying attacks until he reached the borders of Armenia, and had lost more than 20,000 men, the flower of the Roman army.

Antony was no sooner gone than the kings of Media and Parthia quarrelled about the booty which they had taken; and, after various contests, Phraates reduced all Media and Armenia. Elated with his conquests, he then oppressed his subjects in such a cruel and tyrannical manner that a civil war broke out, in which the competitors for the crown were alternately driven out and restored, until the middle of the first century, when one Vologeses, the son of a former king, became the peaceable possessor of the throne. He carried on some wars agains the Romans, but with indifferent success, and at last gladly consented to a renewal of the ancient treaties with that powerful people.

From this time the Parthian history presents nothing remarkable until the reign of the Emperor Trajan, when the Parthian king, by name Chosroes, displeased the Romans by driving out the King of Armenia. Upon this, Trajan, glad of any pretence to quarrel with the Parthians, immediately hastened into Armenia. His arrival there was so unexpected that he reduced almost the whole country without opposition, and took prisoner and put to death Parthamasiris the king, who had been set up by the Parthians. After this, he entered Mesopotamia, took the city of Nisibis, and reduced to a Roman province the whole of that wealthy country.

Early in the spring of the following year, Trajan, who had withdrawn to winter quarters in Antioch, again took the field against the Parthians. Having crossed the Euphrates in the face of a continued shower of arrows from the enemy on the opposite bank, he advanced boldly into Assyria, and made himself master of Arbela. Thence he pursued his march, subduing with incredible rapidity countries where the Roman standard had never before been displayed. Babylonia voluntarily submitted to him, and Babylon itself was, after a vigorous resistance, taken by storm; so that he became master of all Chaldæa and Assyria, the two richest provinces of the Parthian empire. From Babylon he marched to Ctesiphon, the metropolis of the Parthian monarchy, which he besieged, and at last reduced. But whilst Trajan was thus making war in the heart of the enemy's country, Chosroes, having recruited his army, set out to recover Mesopotamia. On his arrival in that province, the inhabitants flocked to him from all parts; and most of the cities, having driven out the garrisons left by Trajan, opened their gates to him. The emperor, however, detached Lucius and Maximus into Mesopotamia to check the revolt. Maximus was met by Chosroes, and defeated and slain; but Lucius gained considerable advantages over the enemy, and retook Nisibis, Seleucia, and other cities. Trajan then repaired to Ctesiphon, and having assembled the chief men of the nation, he crowned one of the royal family, by name Parthamaspates, king of Parthia, obliging all those who were present to engage to pay him allegiance. Thus Parthia was at last subdued and made tributary to Rome.

But the Parthians did not long continue in this state of subjection. For no sooner had they heard of Trajan's death, which happened shortly afterwards, than they drove Parthamaspates from the throne, and, recalling Chosroes, openly revolted against Rome. Hadrian, who was then commander-in-chief of all the forces in the East, and who was soon afterwards acknowledged as emperor, did not wish to engage in any new war with such a formidable enemy. He therefore abandoned those provinces which Trajan had conquered, withdrew the Roman garrisons from Mesopotamia, and fixed the Euphrates as the boundary of the empire in those parts.

Chosroes died after a long reign, and was succeeded by his eldest son Vologeses. In the reign of the latter, the Alani, a barbarous horde, broke into Media, and could only be induced by large presents to return home. His successor, also called Vologeses, having no enemy to contend with at home, fell unexpectedly upon Armenia, cut the legions in pieces, entered Syria, defeated Cornelianus, governor of that province, and advanced without opposition to the neighbourhood of Antioch, putting everywhere the Romans, and those who favoured them, to the sword. The Emperor Verus, by the advice of his colleague, Antoninus the Philosopher, hastened into Syria, and having driven the Parthians out of that province, ordered Statius Priscus to invade Armenia, and Cassius to carry the war into the enemy's own country. Priscus made himself master of Artaxata, and in one campaign drove the Parthians out of Armenia. Cassius, on the other hand, reduced all those provinces which had formerly submitted to Trajan, sacked Seleucia and Ctesiphon, and struck terror into the most remote provinces of that empire. Not long afterwards, Antoninus the Philosopher, repairing to Syria to settle the

Partnership.

affairs of that province, was met by ambassadors from Vologeses. That prince, having by this time recovered most of the provinces subdued by Cassius, promised to hold them of the Roman emperor. To these terms Antoninus readily agreed; and a peace was accordingly concluded between the two empires.

Upon the death of Vologeses, his nephew, who bore the same name, was raised to the throne. He sent troops to the assistance of Pescennius Niger in his contest for the imperial crown. Accordingly, no sooner had Severus, the successful competitor, established his authority at home, than he advanced to punish the Parthians, and laid siege to their capital Ctesiphon. The city was at length taken by assault, and the king's treasures, with his wives and children, fell into the hands of the conquerors. Severus, however, had no sooner crossed the Euphrates than Vologeses recovered all the provinces which he had reduced, except Mesopotamia. On the death of this monarch, a contest for the crown ensued between his sons. Vologeses was at first successful; but Artabanus ultimately succeeded in establishing himself on the throne. He had scarcely settled the affairs of his kingdom when the Emperor Caracalla, desirous to signalize himself by some memorable exploit against the Parthians, sent a solemn embassy to their king, desiring his daughter in marriage. Artabanus complied with his request, and went to meet him, attended with his principal nobility and his best troops, all unarmed. But this peaceable train no sooner approached the Roman army than it was attacked and mercilessly butchered by the soldiers, the king himself escaping with very great difficulty.

This inhuman treachery Artabanus resolved to revenge. Accordingly, having raised the most numerous army that had ever been known in Parthia, he crossed the Euphrates, and ravaged Syria with fire and sword. But Caracalla being murdered before this invasion, Macrinus, who had meanwhile succeeded to the purple, met him at the head of a mighty army composed of many legions and all the auxiliaries of the states of Asia. The battle lasted two days, both nations fighting so obstinately that night only parted them, without any apparent advantage on either side. On the third day the Roman emperor sent a herald to Artabanus, acquainting him with the death of Caracalla, and proposing an alliance between the two empires. The king, understanding that his great enemy was dead, readily embraced the proposal, upon condition that all the prisoners who had been so perfidiously taken by Caracalla should be immediately restored, and a large sum of money paid to defray the expenses of the war.

Partick || Partnership

As Artabanus on this occasion had lost the flower of his army, the Persians, under the command of Artaxerxes, a man of mean descent, but of great courage and experience in war, revolted against the Parthians. They were successful in two battles, and in a third they annihilated the army of their enemies, and took the king prisoner. Artabanus was soon afterwards put to death by order of Artaxerxes; and the Parthians were forced to become the vassals of a nation which had been subject to them for the space of 475 years.

PARTICK, a village of Scotland, county of Lanark, forming a suburb of Glasgow, from which it is about 2 miles W.N.W. It stands near the confluence of the Kelvin with the Clyde, and has many fine villas in the neighbourhood. There are an Established, a Free, and two United Presbyterian churches, several schools, and a literary society. In the village and its vicinity there are large flour-mills, a cotton factory, bleachfields, and ship-building yards. Pop. 2747.

PARTNERSHIP, LIMITED AND UNLIMITED LIABILITY.

Definition.

PARTNERSHIP, in *Political Economy*, the voluntary association of two or more individuals for carrying on some business or undertaking in common, each deriving a certain share of the profits, and generally bearing a corresponding share of the loss arising therefrom.[1]

The term *partnership* is commonly applied to those smaller associations—consisting usually of less than *six*, and not more than *twenty* persons—in which the partners personally conduct their joint affairs: the term *company* being applied to those great associations conducted by directors and servants appointed by the body of the partners to act for them, the latter having no direct concern in the management of the company's affairs.

Partnerships—principle on which founded.

I. *Partnerships*, whether the number of partners be great or small, are founded on that principle of association to which most great results may be ascribed. There are but few industrial undertakings that can be advantageously carried on without the co-operation of different persons. Many of them require a greater amount of capital than is usually at the disposal of individuals; and they almost all require a combination of various capacities and talents. And hence the advantage of uniting together to effect a common purpose. By the union of funds a sufficient capital is obtained. And when it happens, as is often the case, that those who contribute funds are without the peculiar skill or knowledge required to carry on the business, there are always parties to be found ready to supply this deficiency, and to contribute, as their share of the common stock, that science and practical knowledge[2] which the others want, and which are indispensable in all undertakings. And the income of both parties being dependent upon, and proportioned to, the profits which the business yields, they have the most powerful motive to exert themselves, and to put forth all their energies. Nothing can be more beneficial than such an organization. It brings different classes of individuals into the most intimate relationship, elicits their peculiar talents, and makes them mutually serviceable. In a properly-constituted partnership or association, capital, science, and skill are blended in their due proportions; and by their combined action produce results that would otherwise be wholly unattainable.

It happens, indeed, that, like most other things, partnerships are sometimes productive of mischievous results. But these are occasioned either by their perversion or abuse. The public interest requires that the whole partners in a firm should be bound by the acts of any one of their number; so that the folly or fraud of a single partner may entail very serious consequences upon those associated with him. Generally, however, this is not an evil of frequent occurrence; and there can be no question that, both in a private and public point of view, partnerships are highly beneficial. And hence their multiplication. They have grown with the growth of commerce and industry,

[1] *Societas est contractus juris gentium, bonæ fidei, consensu constans, super re honestâ, de lucri et damni communione; quam inire possunt omnes liberam habentes rerum suarum administrationem.* (Voet. *Comm.*, lib. xvii., tit. ii., § 1.)

[2] *Ita posse coiri societatem non dubitatur, ut alter pecuniam conferat, alter non conferat; et tamen lucrum inter eos commune sit, quia sæpe opera alicujus pro pecuniâ valet.* (*Instit.*, lib. iii., tit. xxvi., § 2.)

Partnership.

and have been at once a cause and a consequence of the extraordinary extension of the businesses carried on by their agency.

Leading principles in the law of partnership.

To enter into anything like a full discussion of the law of partnership would very far exceed our limits. We shall therefore merely state a few of those leading principles with respect to it with which it is of importance that mercantile men, and the public generally, should be acquainted.

The mere consent of the partners, fixed and certified by acts or contracts, is quite sufficient to constitute a private copartnership; so that if two or more merchants, or other persons, join together in trade, or in any sort of business, with a mutual, though it may be unequal, participation in the profit and loss of the concern, they are in every respect to be considered as partners. If there be no provision to the contrary, each partner would share in the profits according to the value of his contribution to the stock of the partnership, whether it consist of money, goods, skill, or labour; and, under the circumstances supposed, each would share in the loss in the same proportion in which he would have shared in the profit, had there been any. But the proportion of gain or loss to be borne by the various partners may be varied in every possible way. No particular form of words or proceeding is necessary to constitute a partnership. It may be entered into either by an express written agreement, or by a merely verbal one. The former, however, ought in almost all cases to be preferred. The contract of copartnery should state the parties to it; the business to be carried on; the space of time the partnership is to continue; the capital, time, or skill which each is to bring into the common stock, or give to the business; the proportions in which the profit and loss are to be divided; the manner in which the business is to be conducted; the mode agreed upon for settling accounts at the dissolution of the partnership; together with the special covenants adapted to the circumstances of each particular case.

To constitute a partnership, there must be a participation in uncertain profits and losses;[1] and the true criterion to determine whether a party be a partner or not is, to ascertain whether *the premium or profit he receives is certain and defined, or casual, indefinite, and depending upon the accidents of trade.* In the former case he is not, and in the latter he is, a partner. A participation in the profits of any business or adventure, without a participation in the losses, constitutes a partnership so far as to render the individual so participating liable to third parties for the engagements of the concern, though, as between the parties themselves, it may be no partnership. Persons acting merely in the *character of servants* in any undertaking, such as seamen in the whale or seal fishery, and receiving as wages a sum proportioned to the profits made by their employers, are not partners.

If an individual, by his own act or inadvertence, allow himself to appear to the world as a partner, he is precluded from disputing the fact, even though he have no interest in the profits. A partner who withdraws from a firm is liable for its debts should the remaining partners continue his name in the firm, though without his consent, unless he take the necessary precautions to show that he has ceased to belong to it. (See *post.*)

If there be no express stipulation as to the management of partnership business, the majority decide as to the disposition and conduct of the joint affairs of the firm; or if there be but two parties in a firm, one may manage the concern as he thinks fit, provided it be within the rules of good faith, and warranted by the circumstances of the case. The general duty of a partner is to keep in view, at all times and in all transactions, the interest and welfare of the partnership, by acting honestly and as a prudent man would conduct his own affairs. He ought to have no secrets apart from his copartners in matters connected with their common concern; and he ought carefully to abstain from engaging in any business or speculation, whether on his own account or with others, that would divert his attention from the affairs of the partnership, or would clash with, or be inimical to, its interests.

Partners may be avowed, ostensible, or dormant. In regard to the first two there is no difficulty; for whether a man be really a partner, or holds himself out to the public and passes as such, is immaterial in so far as his liability to the latter is concerned. And in the case of dormant partners—that is, of partners who participate in the profits of concerns without disclosing their names—they are as liable as the others the moment it is ascertained that they are partners; and they may be pursued for debts contracted when it was not known that they belonged to the partnership.

Partners may distribute their profits and regulate their affairs in any way they please among themselves; but they cannot by so doing limit, defeat, or elude their responsibility to others. Each partner, however small his share in the concern, is liable, in all ordinary partnerships, for the entire debts of the association. And it is for the advantage of the partners, as well as of the public, that such should be the case. It makes the former peculiarly sensitive in regard to each other's character and conduct, and cautious as to the nature of the transactions into which they enter; and it gives the latter that security to which they are entitled, and on which only they can place any reliance in dealing with the great majority of firms.

The act of one partner is not sufficient to bind the others, unless it relate to, and be connected with, the peculiar business carried on by the partnership: For it is only when they act with reference to the business of their respective firms that partners are to be considered as their accredited agents or delegates; and it is in such cases only that those who deal with them are entitled to rely on the security of the partnerships which they represent. It may sometimes, perhaps, be difficult to say whether a transaction into which a partner is willing to enter be so connected with the business of the partnership as to bind the latter. And in such cases third parties had better be cautious, and decline engaging in a doubtful transaction, unless they have special grounds for placing entire confidence in the partner with whom they are dealing, or have learned that his proceedings are known to, and will be sanctioned by, the firm. In matters which are clearly unconnected with the business of the partnership it is not in the power of one partner, unless under very peculiar circumstances, to bind the others. (Smith *On Mercantile Law*, 5th ed., cap. ii., § 5; Kent *On the Law of Partnership*, p. 37, &c.)

The powers of partners are very extensive. They may pledge or sell the effects of the partnership, or compound for its debts. And they may purchase such goods as they please, having relation to the business of their firms, provided there be no collusion between them and the sellers, and that no intimation has been made to the latter by the other partners that they will not be bound by the transaction. Partners are not bound by a contract entered into by one of their number as an individual only, and on his own account. But if it have exclusive reference to the business of the firm, the presumption is, that it has been entered into upon its account; and this presumption is not

[1] **A partnership in which all the profit is to go to one set of partners, and all the loss to the others, was called by the Roman lawyers a *leonine* society (*societas leonina*), from the lion, who, though assisted by other animals in his hunting expeditions, took all the prey to himself. (Phædrus, lib. i., Fab. 5.)**

Partnership.

to be disputed except by distinct and conclusive evidence. One partner cannot, as such, bind another by *deed*, except in bankruptcy.

Partners, though they should act in a fraudulent manner as respects their copartners, bind the firm in all matters connected with its peculiar dealings. But this rule will not hold unless the strangers or third parties with whom a fraudulent transaction has been concluded, have acted *bona fide*. Any knowledge of, or participation in, the fraud on their part will vitiate and upset the transaction, and relieve the partnership from its responsibility. And though the fraud were not really known to the third party, yet, if the circumstances were such as ought to have led a man of ordinary discernment to suspect there was something wrong —that the partner with whom he was dealing had no authority to act for the others, or that the transaction had a suspicious character—it would be set aside. In such cases, excess of negligence or stupidity has the same consequences as connivance or guilty knowledge. "There is no doubt," said Lord Mansfield, "but that the act of every single partner, in a transaction relating to the partnership, binds all the others. But there is no general rule which may not be infected by 'covin,' or by such *gross negligence* as may amount or be equivalent to covin; for covin is defined to be a contrivance between two to defraud or cheat a third." (Smith, *ubi supra*, p. 44.)

Parties have frequently been not a little surprised to find that they were, unknown to themselves, partners in bankrupt firms, and, as such, responsible for their debts. Nothing is more common than for books to be printed and published, the publisher taking the risk of the publication and defraying its cost, the author getting for his remuneration half the profits, should there be any, which is not often the case. This, however, is clearly a partnership transaction. And in the event of the failure of a publisher who has published a work in the way now stated, the printers, papermakers, binders, and others engaged in bringing it out, supposing their bills have not been paid, fall back upon the author, who, being a partner in the speculation, is bound to discharge their claims! Cases of this sort are not imaginary merely, but have occurred over and over again. This, indeed, is a matter in regard to which the writer of this article may truly say, "*Haud inexpertus loquor*." And such being the risks which authors who enter into engagements of this sort have to encounter, they will do well, before embarking in them, carefully to inquire into the character and position of the publishers with whom their interests are to be associated.

The authority of a partner is revocable; and it is fully established that a *disclaimer* of the authority of the partners in any particular transaction precludes the individual by whom it is made from binding his copartners. Even during the subsistence of the partnership one partner may to a certain degree limit his responsibility; and if there be any particular speculation or bargain proposed of which he disapproves, he may, by giving distinct notice to those with whom his partners are about to contract that he will not be concerned in it, relieve himself from the consequences. Such notice would rebut his *primâ facie* liability. The partnership would be suspended *quoad* this transaction. Thus, if a partner draw, accept, or indorse a bill or note, he will, in all ordinary cases, thereby render the firm liable. But, to use the words of Lord Ellenborough, "it is not essential to a partnership that every partner should have such power; they may stipulate among themselves that it shall not be done; and if a third party, *having notice of this*, will take such security from one of the partners, he shall not sue the other upon it, in breach of such stipulation, nor in defiance of notice previously given to him by one of them that he will not be liable for any bill or note signed by the others." (*Galway* v. *Matthew*, 10 East, 264.) And so in other cases.

When one of the partners has been made liable for the debts of the firm, he must seek his remedy in a rateable contribution against the others. Should one party enter into a smuggling or other illegal transaction on the partnership account, the other partners are liable for the duties and the penalty; and it is optional with the Crown to proceed against the real delinquent only, or against his partners. A bookseller or newspaper proprietor is answerable for the acts of his agent or copartner, not only civilly, but also *criminally*.

Dissolution of partnerships.

A partnership may be dissolved by the effluxion or expiration of the time during which it was originally agreed that it should continue. When it is formed for a single transaction, it is at an end as soon as it is completed. Partnerships may also be dissolved by death, agreement, bankruptcy, outlawry, &c. A court of equity will interfere to dissolve a partnership if a partner evince such gross carelessness or misconduct as would be ruinous to the firm, or would defeat the object for which the partnership was formed; or when a partner becomes insane, or is in such a state of mind as to render him permanently incapable of transacting the peculiar business of the firm; or where a partnership is formed for an impracticable purpose. Indeed, in all cases where even a partnership may be dissolved without the interference of a court of equity, it may be most prudent, if the dissolution be opposed by one or more of the partners, to file a bill praying a dissolution and account, and an injunction against using the partnership name.

When a partnership is dissolved by agreement, or one of the partners withdraws from it, public notice of the dissolution should be given in the *London Gazette*, and a specific intimation of the circumstances should be sent to all individuals accustomed to deal with the firm. Where such intimation has not been sent, an individual withdrawing from a firm may be made liable to third parties after he has ceased to have anything to do with it. He should also take care that his name is struck out of the firm; for if it be allowed to remain in it, strangers may suppose that he is still one of the partners, and he may thus be rendered responsible to them. A dormant partner, however, whose name has never been announced as belonging to a firm, may withdraw from it at pleasure without taking any step to disclose the dissolution of partnership.

Names of partners should be published.

It would, however, be expedient, in the view of getting rid of the serious inconveniences to which partners withdrawing from firms are sometimes subjected, and still more, of giving to the public that authentic information to which they are entitled, that the names of all partners in all partnerships, whether great or small, should be periodically published, and hung up in their places of business. Those who have to transact with firms, being in this way made aware of the individuals with whom they are really dealing, would act accordingly. But at present nothing may be known of these matters, or, if known, it may be by a few only; and there is no security whether, if inquiries were made regarding the matter, they would be truly answered. It is not by any means uncommon for firms to be continued under certain names long after the parties who bore them have ceased to exist, and without their having left either descendants or representatives of any sort in the business. And the designations A. B. & Co., A. B. C. & Co., and such like, are often assumed when in truth the Co. is a mere fiction. In these and similar cases the public is apt to be deceived, and to suppose that it is dealing with certain parties, when, in fact, it is dealing with totally different parties. But as such deceptions and ambiguities are uniformly mischievous, they ought to be put an end to, and firms proclaimed to be what they really are.

Partnership.

We therefore are disposed entirely to approve of the principle of the bill introduced into Parliament during the session of 1858 (by Lord Goderich) for the compulsory registration of the partners in partnerships. The clamour that was raised against it was most unreasonable. It could make no improper disclosures; for if a man be ashamed of being in a partnership, the sooner he leaves it the better it will be for himself and all concerned. Neither did it interfere in any manner of way with the freedom of industry or of association, or lay any restriction on one thing or another. Its sole object was to let in light on a few dark places; to show who Messrs A. B. & Co. really were. It eliminated fictitious names, and disclosed real and sleeping partners; but it did nothing more. It made no suggestions and gave no directions. And we have yet to learn that any wrong could be done to any honest man by its disclosures, while the benefits of which they would be productive are many and obvious. We have no doubt that some measure having the same objects in view will be eventually carried. It is difficult to suppose that it should be objected to, except by those who desire to be in the dark because it affords greater facilities for the carrying out of sinister projects.

When the joint debts of a firm are paid, and the property duly distributed among the partners, the dissolution may be said, in a general sense, to be accomplished. If any one of the firm be guilty of a breach of duty in misapplying the effects before the concern is finally wound up, the proper course is, to apply to the Court of Chancery to appoint a manager.

Within a reasonable time after the death of a partner, the survivor or survivors must account to the representatives of the deceased; and if not willing to do so, a court of equity will compel him or them. In taking partnership accounts at the death of a partner, they must commence with the last-stated account, or, if there be none such, with the commencement of the partnership; and they must end with the state of the stock at the time of the partner's death, and the proceeds thereof until it be got in.

No notice is necessary to third parties of the death of a partner; the partnership is dissolved, and all liabilities for subsequent acts cease. The surviving parties are to be sued alone for the partnership liabilities and obligations, for which they are liable to the full extent. But they are not liable for the separate debts of the deceased partner, unless, after payment of the joint debts, they have a surplus of partnership effects in their hands.

Upon a dissolution by death, if the joint effects be insufficient to pay the partnership debts, the separate estate of the deceased partner, if he have any, is liable for the deficiency.

The statements now made may probably be sufficient to give our readers a tolerably distinct notion of the formation of partnerships, and of the more important rights, duties, liabilities, &c., arising out of such institutions. Those who wish to go deeper into the subject may consult Collyer's *Practical Treatise on the Law of Partnership;* Chitty's *Commercial Law,* vol. iii., pp. 22–269; Woolrych *On Commercial Law,* pp. 298–317; Smyth *On Mercantile Law,* 5th ed., pp. 19–56; &c.

Formation and constitution of joint-stock companies.

II. *Companies.*—By a company, in commerce and the arts, is meant a copartnery or association of sundry (in Great Britain, at least *seven*) persons united together for the prosecution or carrying on of some lawful business or pursuit. The capital or joint stock of a company is greater or less according to circumstances; but whatever may be its amount, it is uniformly raised by the issue of such a number of shares of such magnitude as those interested may think expedient; the individuals enrolled in the books of the company as the holders of these shares being its partners. Owing, however, to the latter being in most instances very numerous, living at considerable distances from each other and being commonly engaged in other pursuits, it is impracticable for them personally to conduct the company's affairs. These are, in consequence, entrusted to the management of a board of directors, elected by, and responsible to, the shareholders. The latter, in fact, can do nothing individually. All their resolutions are taken in common, and are carried into effect by the directors they have chosen, and their officers. "In a private copartnery," says Adam Smith, "no partner, without the consent of the company, can transfer his share to another person, or introduce a new member into the company. Each member, however, may, upon proper warning, withdraw from the copartnery, and demand payment from them of his share of the common stock. In a joint-stock company, on the contrary, no member can demand payment of his share from the company; but each member may, without their consent, transfer his share to another person, and thereby introduce a new member. The value of a share in a joint-stock is always the price which it will bring in the market; and this may be either greater or less, in any proportion, than the sum which its owner stands credited for in the stock of the company." (*Wealth of Nations,* p. 333.)

Unlimited liability of partners at common law.

According to the common law of England, all the partners in joint-stock companies, without regard to the magnitude of the shares held by them, are jointly and individually liable, to the whole extent of their fortunes, for the debts of the companies. They may make arrangements among themselves limiting their liabilities with respect to each other; but unless established by authority competent to set aside the general rule, the partners are all indefinitely liable to the public. In some instances, however, Parliament interfered to limit the responsibility of the shareholders in joint-stock companies to the amount of their shares. And the act 6th Geo. IV., c. 96 empowered the Crown to grant charters of association to companies, the partners of which might be made liable to such an extent, and subjected to such regulations, as might be deemed expedient. And hence charters were sometimes granted for the purpose merely of enabling companies to sue and be sued in the courts of law, in the names of their office-bearers, without in anywise limiting or affecting the liability of the shareholders to the public. Such limitation was not to be implied by the grant of a charter, and was not held to exist unless it were distinctly set forth.

Limited liability of shareholders generally introduced in 1855.

It is much to be regretted that the liability of the shareholders has been still farther interfered with, and that, in this respect, a very serious inroad has been made on the old law of the country. The act of 1855 (the 18th and 19th Vict., c. 133) authorizes the establishment of companies for the carrying on of most descriptions of businesses (banking and insurance were excepted), the liability of the partners in which may be limited to the amount of their shares. And hence it results, that in all cases in which these have been fully paid up, the partners are relieved of all responsibility, and are no longer liable for anything. Though the bankruptcy of the companies to which they belong may occasion the ruin of thousands, they cannot be called upon to contribute a single farthing to the relief of distresses that have most probably been caused by their misconduct!

Well might the highest authority who can be appealed to on such subjects charge this system with injustice; for, as he observes, "in the case of the insolvency of a concern, it removes a portion of the loss, which must be borne by some party, from those who have voluntarily engaged in the concern, who have had the means of watching and controlling its progress, and who would have been the sole participators in the benefits of its success, for

Partnership.

the purpose of throwing it upon those who have had no means of insight into the state of the concern, no power over its management, and no share in its advantages. The *commandite* partners may have embarked a very small share of their property in the concern, and must, therefore, be very slightly injured by its failure; whilst those to whom it is indebted may be very seriously injured, even to the extent of ruin."[1]

Defective state of the law in regard to joint-stock companies.

Besides being vicious in principle, the law under which joint-stock companies are established is not a little confused and contradictory. Speaking generally, it may be said to be embodied in the act of 1856, the 19th and 20th Vict., c. 47, as amended by the act of the following year, the 20th and 21st Vict., c. 14. In the event, however, of a company being formed which requires peculiar or extraordinary powers,—such as the right to make roads or canals, to take up streets that gas or water pipes may be laid, and such like proceedings,—recourse must still be had to Parliament. But except in cases of this sort, the acts referred to are sufficient. And all partnerships or companies for ordinary industrial purposes, if they consist of more than twenty partners, *must* be established or registered under these acts, and made conformable to them; while, if they consist of seven and under twenty partners, they *may* be so established or registered; and in either case the liability of the partners may be limited to the amount of their shares, or be made or kept indefinite, as they may judge best. In like manner, banking companies with more than ten partners *must*, and those with seven and under ten *may*, be established, and must be registered under the act 20th and 21st Vict., c. 49; but, as already stated, the liability of the partners in such companies was not limited by the acts referred to. In addition to the clauses in the acts now mentioned as regulating the constitution of new and modifying that of old companies, there are others which relate to their voluntary and compulsory winding-up, their bankruptcy, &c. And, whether it were intended by Parliament or not, the effect of these statutes has been materially to modify the former indefinite liability of the partners in ordinary joint-stock companies. These associations have been, by a sort of legislative hocus-pocus, metamorphosed into incorporations; so that their funds only are liable to be taken in execution by their creditors. The rights of the latter have, in truth, been sacrificed without compensation or equivalent of any sort. A creditor cannot now, as he could have done three years ago, pounce upon any shareholder he pleased, and pursue him for payment of his debt, leaving to the shareholder to seek an indemnity from his copartners. When the funds of a company, supposing the liability of the partners to be unlimited, are insufficient to make good its engagements, a petition is presented to the Court of Chancery praying to have the company wound up. On this being done, the creditors can take no farther steps in the matter, but must wait the result. The court may order calls to be made sufficient to pay the debts due by the company. But this is always a very slow process; and if the creditors get paid in the end, which may be doubtful, it can only be after they have been kept out of their money for lengthened periods, most probably for a considerable number of years.[2]

We do not suppose that regulations having such consequences are likely to be permanent. Their nature and influence were not declared, and were indeed very imperfectly known, and that only to a few members, when they were before Parliament; but the longer they are maintained, the more mischievous will they be found to be. It is not going too far to say, that the present state of the law in regard to the constitution, winding-up, and bankruptcy of joint-stock companies is more than discreditable, that it is disgraceful to the country. Had its object been to introduce fraud and recklessness into their constitution and management, and delay and expense into the legal proceedings to which they may give rise, it is doubtful whether it could have been materially improved.

Undertakings which may be successfully carried on by joint-stock companies.

But supposing that joint-stock companies are properly organized, that the liability of the partners is unlimited, and that creditors have every facility given them for getting payment of their debts, still there are only certain varieties of undertakings to which they can be advantageously applied. To insure a reasonable prospect of success to a company, the undertaking should admit of its being carried on according to a regular systematic plan. The reason of this is sufficiently obvious. The business of a great association must be conducted by factors or agents; and unless it be of such a nature as to admit of their duties being clearly pointed out and defined, the association would cease to have any effectual control over them, and would be in great measure at their mercy; and, however conscientious and anxious to do their duty, they want the powerful motives to act vigorously, prudently, and economically, by which private individuals engaged in business are actuated. "Like," says Adam Smith, "the stewards of a rich man, they are apt to consider attention to small matters as not for their master's honour, and very easily give themselves a dispensation from having it. Negligence and profusion, therefore, must always prevail more or less in the management of the affairs of such companies." It also not unfrequently happens that they suffer from the bad faith, as well as the carelessness and extravagance, of their servants; the latter having in many instances endeavoured to advance their own interests at the expense of their employers. Hence the different success of companies whose business may be conducted according to a nearly uniform system, and those whose business does not admit of being reduced to any regular plan, and where much must always be left to the sagacity and enterprise of those employed. All purely commercial companies trading upon a joint stock belong to the latter class. Not one of them has ever been able to withstand the competition of private adventurers; they cannot subject the agents they employ to buy and sell commodities to any effectual responsibility; and from this circumstance, and the abuses that usually insinuate themselves into every department of their management, no such company has ever succeeded, unless when it has obtained some exclusive privilege or been protected from competition.

And even with these advantages, such is the negligence, profusion, and peculation inseparable from the management of great commercial companies, that those that have had the monopoly of the most advantageous branches of commerce have rarely been able to keep out of debt. To buy in one market; to sell with profit in another; to watch over the perpetually occurring variations in the prices, and in the supply and demand of commodities; to suit with dexterity and judgment the quantity and quality of goods to the wants of each market; and to conduct each operation in the best and cheapest manner, requires a degree of unremitting vigilance and attention which it would be visionary to expect from the directors or servants of a joint-stock association. Hence it has happened, over and over again, that branches of commerce which proved ruinous

---

[1] From a paper drawn up by Lord Overstone when the subject of limited liability was first mooted in 1837. Subsequent experience has confirmed the accuracy of his lordship's views.

[2] Wordsworth's *New Joint-Stock Company Law of* 1856 *and* 1857, passim.

Partnership.

to companies have become exceedingly profitable when carried on by individuals.

"The spirit of monopolists," to borrow the just and forcible language of Gibbon, "is narrow, lazy, and oppressive. Their work is more costly and less productive than that of independent artists; and the new improvements so eagerly grasped by the competition of freedom are admitted with slow and sullen reluctance in those proud corporations, above the fear of a rival, and below the confession of an error."[1] (*Memoirs of his own Life, Miscellaneous Works*, i., p. 49, ed. 1814.)

But though in all respects unsuited for the prosecution of ordinary industrial pursuits, whether belonging to agriculture, manufactures, or commerce, there are, as stated above, various undertakings for which joint-stock companies are peculiarly well fitted, and for which, indeed, they appear to be indispensable. The railways and canals which intersect most parts of the country; the docks and warehouses in our great seaports; the gas-works and waterworks with which almost all our towns, whether great or small, are provided; and the greater portion of the public buildings and institutions by which they are embellished and the citizens amused and instructed, owe their existence to joint-stock companies. They are works that could not have been undertaken or completed except by the united capital and energies of great numbers of individuals; and being for the most part conducted on fixed principles, and according to a uniform system, their management, though not generally productive of much advantage to the shareholders, has, on the whole, been creditable to those concerned. It is not easy, indeed, to overrate the advantages which this country has derived from joint-stock associations, when applied to proper objects, and conducted by men of probity, skill, and caution.

The question in regard to the suitableness of joint-stock companies to conduct the business of banking has been frequently agitated, and is one of some difficulty. But as we have already treated this question at considerable length in the article MONEY, it is needless to resume the discussion in this place. Here it will be sufficient to observe, that much depends on the regulations under which joint-stock banks may be placed. And supposing that the unlimited liability of the partners is maintained and easily enforced, and that the bad faith or gross mismanagement of the directors is visited with suitable penalties, it is probable that the principal objections to joint-stock banks would be either removed or greatly diminished.

Limited liability in France, &c.

Partnerships with limited liability have been established in France, in the United States, and in other countries. In most cases they are subjected to peculiar provisions, but otherwise they may be instituted in a great variety of ways. Thus the responsibility of the partners may be limited to the amount of the sums which they have respectively contributed to the common stock, or to some multiple of these sums; and the power of the partners to interfere in the management of the company may be very variously regulated. The French call associations of this sort, partnerships *en commandite*. They consist of partners, or *commanditaires*, who are responsible only for the amount of their shares, and of a *gérant*, whose liability is unlimited, and who, at the same time that he is independent of the partners, has the entire management of the concern.[2] These institutions have existed in France for a lengthened period, but it is only of late years that they have been widely diffused. Latterly, however, their increase has been such that it was stated in a speech made in the *Corps Legislatif* in 1856, that more societies *en commandite* are now established in a single year than had formerly been established in half a century or in ten years of the reign of Louis Philippe. And this extraordinary increase of these societies, and the abuses of all sorts with which vast numbers of them have been infected, have attracted a large share of the public attention to their constitution, and occasioned various efforts for its improvement. But it was admitted on all hands that, down at least to 1856, the efforts referred to had been wholly ineffectual for any good purpose, and that the public was very often defrauded by the fallacious representations that were put forth in regard to the state of partnerships, by the declaration of dividends when, in fact, there was nothing to divide, and all those fraudulent devices of which we have recently had such extensive experience. And such has been the influence of this state of things, that, despite the many prejudices in favour of the system, it is believed by some high authorities that its entire suppression would be desirable.

In the meantime, however, a new law, which was the subject of a great deal of discussion, was passed in 1856 (promulgated 23d July) for the regulation of partnerships *en commandite*. But though it be in various respects an improvement on the law which it superseded, there are no good grounds for supposing that either this act, or that any other possible act, will be able to prevent abuse. It limits the amount of the shares according as the capital of the society is above or below 200,000 francs; it directs that one-fourth part of the capital shall be paid up before the business for which it has been formed can be undertaken; and it vests the entire conduct of the business, whatever it may be, in the *gérant*, or manager chosen by the partners. Inasmuch, however, as it has been found that *MM. les gérants* have very frequently issued the most deceptive statements in regard to the companies to which they are attached, a committee of *surveillance*, consisting of five members, is to be chosen in each partnership, who are to verify *les livres, la caisse, le portefeuille, et les valeurs de la société;* and the *gérant* and the committee of *surveillance* are to be subjected to very severe penalties if they knowingly emit any false representations of the state of the society. They must be sanguine indeed who suppose that a clumsy contrivance of this sort can have any effect, unless it be to multiply all sorts of abuses, to increase "*le grand nombre de mauvaises sociétés en commandite*" that existed in France when it was established. And such, we are assured, is the case. What was bad in these societies in 1856 is much worse in 1858.[3]

The French seem to suppose that by making the *gérant*

[1] The Abbé Morellet has given, in a tract published in 1769, *Examen de la Réponse de M. N.*, pp. 35–38), a list of 55 joint-stock companies for the prosecution of various branches of foreign trade, established in different parts of Europe since 1600, every one of which had failed, though most of them had exclusive privileges. Most of those that have been established since the publication of the Abbé Morellet's tract have had a similar fate.

[2] Exclusive of the societies or partnerships referred to above, there are in France *Sociétés Anonymes*, which are nearly identical with our incorporated companies, and *Sociétés en Nom Collectif*. The latter are ordinary partnerships, in which the partners are jointly and severally liable to the utmost extent for the debts of the partnership.

[3] We borrow the following statements from a paper of the 20th March 1858:—"Companies *en commandite* are giving a good deal of occupation to the courts of law here, just as directors of banks are doing in London, and the revelations that are made respecting them are well worth the consideration of that very numerous portion of the English commercial world which is interested in French speculations. Within the last few days the Tribunal of Correctional Police has condemned one honest gentleman (*gérant*) of the name of Damonien to imprisonment and fine, for having swindled the unfortunate shareholders of the 'Compagnie Parisienne des Equipages de Grande Remise' out of L.20,000 in cash and shares, having plunged them into debt to the amount of L.80,000, and having squandered all their capital, amounting to L.320,000. To be sure, he had what he called an 'idea,' which was to get up the company in shares; but

Partnership.

indefinitely responsible to the public, and independent of the company, they will obtain at one and the same time the advantages of individual enterprise and economy with the limited liability of the partners. But while these results are all but incompatible, the attempt to combine them seldom fails to have others that are highly pernicious. A manager who is really independent, and may conduct a company as he pleases without let or hindrance on the part of its members, is extremely apt to conduct it with a view mainly to his own interests, how much soever they may be at variance with those of his nominal constituents. To obviate this risk, the partners most commonly endeavour to select a manager on whose concurrence with, or subservience to, their views they think they may depend. And supposing them to succeed in this object, all the advantages said to be derived from the independence of the manager are at an end, and he becomes a mere instrument for carrying out the views of a clique of irresponsible partners. Hence in very many cases the *gérants* are in reality mere men of straw, directed by the disguised but well-understood hints or commands of the leaders of the association, who, secure in their non-liability, are enabled to gamble on a large scale, and to engage in any sort of adventure.

Limited liability in England unnecessary and mischievous.

The limited liability companies established in this country are relieved from the foppery of legislation now adverted to. Except in the license given them to contract an unlimited amount of debt, without being liable for more than a limited and, it may be, an inconsiderable amount of shares, they do not in other respects differ from ordinary companies. They are managed by boards of directors, whose duties are the same in their case as in that of others.

In countries like France, where the people are mostly in narrow circumstances, and unaccustomed to, and afraid of, speculative enterprises, there may perhaps be some ground for permitting the formation of partnerships *en commandite*. And if they were confined to undertakings that admitted of being carried on according to a system of routine, such as railways, canals, fire and life insurances, gas-works, and so forth, we do not know that they would be open to much objection. But in a country like this, where capital is abundant, and where all enterprises, however hazardous, that promise anything like a reasonable return are eagerly undertaken, all extraordinary inducements to make capitalists come forward are unnecessary, and therefore objectionable. We admit, indeed, that in the case of companies of the special class now alluded to, though nothing be gained, there is no great hazard of much being lost by the shareholders being endowed with the privilege of limited liability. Such companies are not easily perverted to improper purposes; and though the capital of the shareholders may be unprofitably expended, yet, as it is most commonly laid out on visible, permanent, and sometimes valuable works, there is a fund on which the creditors, in the event of the concern failing, may fall back. But modifying circumstances of this sort have very rarely any place in companies formed for conducting ordinary industrial or commercial businesses. In their case the entire capital of the association may be lost or embezzled, without a farthing being left to the creditors. And it is, moreover, if anything can be, a contradiction and an absurdity to suppose that ordinary industrial pursuits can be so well managed by great associations of any sort, whether the partners be indefinitely responsible or not, as they will be by individuals or small associations. The latter act on their own account, and reap all the advantages of superior skill, attention, and economy, at the same time that they are indefinitely responsible for all the losses they may incur, and for all the mistakes into which they may fall, whether in the contrivance or the execution of their projects.

But though great public companies be unsuitable for the conduct of all save routine businesses, the fair presumption, or rather we should say, the certainty is, that those in which the responsibility of the partners is limited, will be much more unsuitable, and more productive of mischievous results, than those in which there is no such limitation. It must, indeed, be conceded, that despite the heavy responsibility under which the partners in ordinary associations or partnerships now act, they too often display an inexcusable degree of foolhardiness. But it is probable that the recent experience of the ruin that may result from placing too much confidence in directors will lead to an improvement in this respect, and that the character and conduct of these functionaries will be more carefully inquired into. Independently, however, of this circumstance, those who compare the number of associations which have been ruined by the bad faith, incapacity, or mismanagement of certain sets of directors, and the carelessness and misplaced confidence of others, will, after all, find that they bear but a small proportion to the total number of such associations. Bankruptcy and insolvency, though treated with infinitely too much indulgence, are still, speaking generally, very serious calamities; and, except when the partners have associated for sinister purposes, or when they have an overweening confidence in their managers, they seldom fail to inquire into the condition of the association, and to adopt such measures as may be judged needful to

he made the shareholders recompense him for the 'idea' by a grant of paid-up shares to the amount of L.60,000. Part of the operations of the company was to buy up small livery stables; and the *gérant* made purchases in his own name, and sold them to the company for considerably more than he paid for them: in one case he made the company give him L.60,000 for what cost him L.36,000. The same tribunal has also had to condemn the *gérants* of another company, called the 'Lignéenne,' which professed to make paper from wood: its nominal capital was L.160,000, and of that sum the *gérants* took L.40,000 for a patent they brought into the concern, while they sold for their own advantage, and for whatever they would fetch, L.40,000 worth of shares, and coolly embezzled all the money the shareholders paid in, and all that could be borrowed. In another case before a tribunal, it appeared that a brace of knowing gentlemen had entered into an arrangement with some bankers to palm off on the public, for L.280,000 or L.320,000, some forests and mines in some outlandish region on the banks of the Danube which they had purchased for L.40,000. In another case, it appeared that the *gérants* of a mining company near Aix-la-Chapelle deliberately sold to their shareholders mines for L.100,000 which they were afterwards obliged to admit were worth only L.60,000. It would be easy to cite other cases of recent occurrence in which revelations not less startling have been made; but these few will suffice to enlighten the public. It must not, however, be forgotten that a case more scandalous than any of them has yet to be brought before the courts—that of M. Prost, of Discount Bank notoriety, who has defrauded his shareholders of many millions (of francs), and who has taken to flight. By the way, these shareholders had a general meeting a few days ago, and after a good deal of most vehement abuse of Prost and his '*Conseil de Surveillance*,' they nominated a committee of five of their body to make a searching investigation into their affairs, in order to ascertain precisely to what extent they have been robbed.

"Other companies *en commandite* there are which, though not falling or likely to fall into the hands of justice, have subjected the shareholders to grievous loss. I refer to those of which the shares during the speculating mania brought enormously high premiums, but which have now fallen to their true value. Thus the shares of the *Messageries Imperiales* once obtained 1510 francs; they are now at about 550 francs. The shares of the company '*des Petites Voitures*' were, shortly after being issued, at 210 francs; they are now to be had for 40 francs. The shares of the Union Company once sprung up almost at a bound from 395 francs to 500 francs; and 65 francs is about the present quotation. People at one time were very glad to give 750 francs for shares in the *Franco-Americaine* Navigation Company; now they can have as many as they like for 30 francs. The Amalgamated Gas Company shares at one time were done at 1120 francs; yesterday they were at 720 francs. And the difference between the past and the present value of the shares of the famous *Crédit Mobilier* is known to everybody."

Partnership.

improve its situation and prospects. This cautious *surveillance* is, of course, less manifested in great associations, where ordinary individuals feel that their efforts are apt to be of little avail; but even in their case it is always forcing itself into notice, while in smaller associations, or those comprising comparatively few partners, each being fully alive to his responsibility, exerts himself to obviate extravagance or mismanagement in the conduct of the business, and to make it a source of profit.

Without, however, insisting farther on these considerations, if parties will every now and then be careless of their interests, and forget or decline to adopt the necessary precautions to guard against abuse and loss when everything they have is staked on the result, their carelessness, it is obvious, will be immeasurably increased when they may limit their liability at pleasure, and speculate without any fear of the consequences. Can any one doubt that, under such circumstances, wild projects of all sorts will be very greatly increased; and that the number of those extensive bankruptcies which are productive of so much misery will be largely augmented? To suppose the contrary is to suppose what is plainly contradictory. It is equivalent to supposing that a man cares as much for L.1000 as for L.5000 or L.10,000, or any greater sum; or is as anxious about a small part as about the whole of his fortune, how large soever it may be.

Facilities which limited liability gives for organizing swindling associations.

It is obvious too, on the slightest consideration, that the facilities for organizing fraudulent and bubble companies have been greatly extended by the new system. A few half-employed attorneys, half-pay officers, and men upon town, with abundance of time on their hands and little money in their pockets, have no difficulty in establishing non-liability companies. They meet together and project an association for some purpose or other—it matters little whether it be practicable or not—which they affirm will yield a profit of some 10, 20, or 30 per cent. after all expenses are deducted. And having hatched their scheme and issued their prospectus, they sally forth to canvass for subscribers. They assure those to whom they address themselves that the project is sure to succeed; that their liability being limited, they run no risk; and as the shares are only some L.20 or L.50, of which not more than a half is required, they advise them as "friends" not to miss an opportunity, which is not likely to recur, of providing for their families, making themselves independent, or adding to their fortunes! And, what with this sort of blarney, the puffs and paragraphs of newspapers, and, above all, the legislative guarantee against risk, they seldom fail of accomplishing their object; that is, of becoming directors, secretaries, managers, and such like dignitaries. The reader must not suppose that this is an imaginary picture. It has been over and over again realized to the very letter in the getting-up of not a few of the non-liability companies that have been set on foot in England during the last two or three years. The affairs of some of them have already come before the courts of law; and if we took these for samples of the others, we should have to regard them as little better than mere swindling engines. But it would not be fair to conclude from the instances referred to that such was their uniform character. A good many have no doubt been honestly got up; and the greater number of these being for routine purposes, such as the supply of towns with water and gas, it may be assumed that they will be fairly conducted, and will succeed. But there are very many of a totally different character. And it would be childish to suppose that in any case the same consideration will be given either to their formation in the first instance, or to their future management, that would be given were the partners indefinitely liable. Hence, while the system operates to the prejudice even of the best schemes, it holds out every temptation to set on foot projects with the intention of deceiving and victimizing the public.

Number of non-liability companies no proof of their being required.

The contrivers of the new system tell us that, whatever it may really be, it is at all events popular with the public; and in proof of this, they refer to the great number of companies that have been already formed with limited liability. But no such reference was needed to enable any one to foresee that if a plan were set on foot to enable parties to contract debts without being bound to pay them, it would be eagerly grasped at. Gambling-houses are at present prohibited; but if they were to be licensed, does any one doubt that numbers of them would be opened in most considerable towns? And we should be told that this was a conclusive proof that the prohibition of gambling was disapproved by the public, and that it required the healthy excitement furnished by the newly-opened places of entertainment! But whatever may be the case with this or that institution, one should think that the former facilities for swindling might have sufficed, without giving them further encouragement.

Limited liability will not increase the caution of the public.

But however powerful the deleterious influence of the non-liability system (for such it is when the shares are paid up) on the formation and conduct of companies, we are assured that it will be more than countervailed by the greater caution it will infuse into those who may deal with them. The names and the number of shares held by the partners in such associations, and the magnitude of their capital, or of the "fund" to which their creditors have to look, are all to be made known; so that those who transact business with them will be really aware of what they have to depend upon. But we take leave to say that they will have no such knowledge. Suppose that a non-liability company had a capital of L.50,000 or L.100,000, and that it was wholly paid up when it was established: it may have been greatly reduced, or wholly lost, in the next or in any subsequent year; and yet, as the public can know nothing, or nothing certain, of its losses, and may, on the contrary, suppose it has been successful, its credit may not be impaired, and it may go on extending its business and adding to its obligations after it is really insolvent. Ordinary partnerships, unless they consist of parties of very questionable solvency or character, have seldom any considerable difficulty in obtaining large amounts of credit; and companies, it matters not of whom composed, which are reported to have some L.10,000, L.20,000, or L.50,000 of paid-up capital, will be sure to obtain loans to a much greater extent and with still greater readiness. In their case we have a kind of authorized guarantee for the possession of wealth. And this, it will be said, precludes all room for distrust; so that, unless we had access to very peculiar sources of information, it might be not a little dangerous to question the solidity of such an association; though the whole thing may be a snare and a delusion. The assurance, whether official or otherwise, that a certain amount of capital has been paid up, is really not worth a farthing. But the chances are, that it will, notwithstanding, serve its purpose with the million. It will make that appear to them to be gold which may not even be copper, and enable parties without a shilling to borrow large sums, and to trade or speculate on the means of others. In such cases the public is helpless. There is nothing on which it can rely; and when the imposture is discovered by the bursting of the bubble, no one is to be responsible for anything.

However it may be accounted for, there is nothing that is so lavishly and inconsiderately bestowed as credit. Frequently, indeed, it is rather thrust upon than given to individuals and firms. And it would be ludicrous to suppose that this is a case in which we can place any dependence on the caution of the public. The only real security is in

Partnership.

the discretion, good sense, and, more than all, in the unlimited liability of the partners. They know, or may know, what they are worth, and what they are about, which no one else can know. And in the vast majority of cases they farther know that they will be bankrupts and beggars unless they act prudently and circumspectly. Hence our late legislation is precisely the reverse of what it ought to have been. Instead of diminishing, we should have increased the responsibility of partners, by abstaining from all interference with their indefinite liability, and giving additional stringency to the bankruptcy laws.

That increased caution on the part of the public which it is said will be a result of the new system is really, therefore, no better than moonshine. It can have no practical influence. The only security which in such matters is worth a pinch of snuff consists in the responsibility of partners. It is not to those who deal with this or that house, but to the houses themselves—to the guarantees under which they have been placed—that we must look for protection against foolhardiness and fraud.

It may therefore be reasonably concluded, that in ordinary businesses,—that is, in all businesses for carrying on branches of agriculture, manufacture, or trade,—partnerships with limited liabilities can be neither more nor less than unmixed nuisances. If honestly conducted, they must fail in their competition with private parties; and if otherwise, they will only add to the means, which were already sufficiently extensive, of wasting capital and fleecing the public.

In the scheme laid down by Providence for the government of the world there is no shifting or narrowing of responsibilities, every man being personally answerable for all his actions. But the advocates of limited liability proclaim in their superior wisdom that the scheme of Providence may be advantageously modified, and that debts and obligations may be contracted which the debtors, though they have the means, shall not be bound to discharge. Borrow, say they, as much as you please, and pay as little as you like,—the less, it would seem, the better! And can it be doubted that the adventurous, the needy, the unprincipled, and the desperate, will be eager to avail themselves of such extraordinary privileges? The reckless speculation, and the consequent bankruptcy and ruin, that have on former occasions overspread the kingdom have been trifling compared with the revulsions which may be anticipated, should the new system be allowed to spread its roots and scatter its seeds on all sides. Even the soberest individuals may be tempted to embark in hazardous projects; for, by limiting the risk, they in great measure secure themselve against loss by failure, at the same time that they reap all the advantages of success. Were Parliament to set about devising means for the encouragement of speculation, over-trading, and swindling, what better could it do than to carry out the non-liability system?

Penalties in the 19th and 20th Vict., cap. 47, no security against fraud.

But we shall perhaps be told that these results, though apparently probable, cannot happen, inasmuch as Parliament has provided, by the Joint-stock Companies Act, the 19th and 20th Vict., chap. 47, sect. 14, that in the event of the directors of a company declaring and paying a dividend when the company is known by them to be insolvent, they are to repay the same out of their own pockets.[1] Perhaps the reader may be inclined to think that those who are disposed to trust to a security of this sort are rather easily satisfied. A body of directors who would, under any circumstances, declare a dividend when they knew that the concern over which they presided was bankrupt, will not be kept in the right path by the threat now referred to. The declaration of dividends when there is nothing to divide is not the way in which dishonest directors would be most likely to defraud their constituents and the public. They would make loans to each other, or if that be prohibited or apt to excite suspicions, they may do the same thing indirectly by the intervention of third parties. The capital and credit of the institution may be perverted, abused, and dissipated in a thousand ways before the circumstance becomes known to the public. And when the courts of law begin to inquire into the matter, they may probably find that the directors, like those of the Eastern Bank of London, have gone to enjoy themselves and repair their exhausted energies on the classic shores of the Mediterranean.

It is the merest delusion to suppose that anything, save the unlimited liability of the shareholders, can be made to afford even the semblance of an efficient check over the conduct of directors. And they no doubt may, and frequently do, fail to exercise that degree of *surveillance* over them which is as necessary for their own security as for that of the public. But if so, the fault is theirs, and there is no ground or reason why they should be permitted to escape from its consequences. The public have neither right nor power to interfere in the matter. Directors are the servants of shareholders, and they must answer, and, if needful, suffer, for their proceedings.

Increase of liability without making it unlimited.

Some who are friendly to the principle of limited liability, but who are at the same time aware of the abuses to which it cannot fail to lead if the liability be limited to the mere amount of the shares, say that they would not object to its increase. It has, in consequence, been proposed to fix the liability at double or treble the amount of the shares; so that when a limited company failed, the subscribed capital of which had been fully paid up, the partners would not, as is now the case, be relieved of all responsibility, but would be obliged to make a further payment, if that were required, equal to the amount of their shares, or to double that amount, as might be decided upon. And this would undoubtedly be a very great improvement upon the existing system; for, while it would raise the character of the partners in limited associations, and make them more careful in regard to those they might choose for directors, and more disposed to watch their proceedings, it would make them contribute to the entire or partial relief of those whom they might otherwise have involved in total ruin. If, therefore, the system is to be continued, we should strongly recommend that the liability of the partners should be raised to at least double the amount of their shares. This would add to its solidity, and divest it of some of its worst features.

But, after all, this is only paltering with or mitigating an evil which should be cut up by the roots. Every sound principle is outraged when a man who has the means of paying his just debts does not pay them. Whether they are contracted by himself directly, or in company with others, is of no importance. He is in either case bound to pay them; and to pass laws to protect him in declining to pay them is to give a legislative sanction to dishonesty and villany.

The prohibition of limited liability not an improper interference with the freedom of industry.

It is alleged, however, that these representations are fallacious; that it is a manifest encroachment on the great principle of the freedom of industry to hinder individuals from engaging in partnerships under such conditions as they may choose to lay down; that in the event of these conditions being publicly declared, and everybody made aware

[1] This is the statement in the body of the act; but in the "Regulations for the Management of Companies" attached to it we are told that "no dividend shall be payable, except out of the profits arising from the business of the company." We of course do not presume to decide whether this or the other statement be the more correct; but their contradictory nature affords a curious illustration of the slovenly, slipshod style in which the most important statutes are often compiled.

of what they are, they cannot be justly objected to; for as it is optional to deal or not deal with the association, those who dislike the conditions upon which it is established may keep aloof from it. But sophistry of this sort is too transparent to deceive any one, and might, in truth, be employed to excuse almost any sort of jugglery or delusion. The question is not whether limited liability be consistent with this or that abstract principle, but what are its practical results—what its probable influence over that public well-being, to promote which either is or should be the object of all legislation? It is with its operation in this respect, and with it only, that we have to deal. Publicans and carriers have made frequent attempts to limit or reduce their heavy responsibilities to those who make use of their services. But the great principle of public utility stood in the way of their claims; and they have not yet succeeded, and it is to be hoped never will succeed, in effecting their object; though ten times more may be said in favour of their exemption from indefinite liability than can be said in favour of the exemption of those engaged in ordinary businesses. If, indeed, there be one principle which more than another conduces to the public advantage, and may be said to constitute the foundation of all dealings between man and man, it is the obligation to discharge one's debts and obligations. And when such is the case, it is the bounden duty of government strictly to enforce the rule of unlimited liability, unless in cases, if such there be, when it can be clearly made out that the public interests will be better promoted by its relaxation or suspension. If a case of this sort be satisfactorily established, then undoubtedly the rule referred to should be waived in as far as it is concerned. But we entirely deny that, when tried by this test, it either has been or can be shown that partnerships *en commandite* are publicly advantageous. On the contrary, we have seen that they are in the last degree injurious, and that it is not possible they should be extensively introduced without giving an immense stimulus to fraud and reckless speculation.

In dealing with ordinary firms or associations, people trust, or believe they may trust, to the reputation for skill and integrity, and to the presumed wealth, of one or more of the partners. Such presumptions are not, indeed, always to be depended upon. In these, as in other matters, people may be misled by appearances, and may place an unmerited degree of confidence in earnest though insincere professions and promises. But how deceptive soever, the presumptions or indications referred to afford not merely the best, but the only guarantees that can really be had for upright conduct. Most people engaged in business, as hitherto carried on, are impressed with the well-founded conviction that their interests will be best promoted by their preserving an unblemished reputation; and when they act under the heaviest responsibility, the chances are ten to one that they will behave discreetly and honourably. But we have no such guarantees for the conduct of the partners of a society *en commandite*. Character is in their case of little, or rather of no consequence. Instead of being responsible, they are all, or may be all, but irresponsible. A, who is worth L.50,000 or L.100,000, has not more, perhaps, than some L.1000 or L.2000 vested in the society. Whether he lose or gain by such investment is a matter about which he probably cares very little. Most likely he has joined the association that he might engage, without fear or apprehension, in the boldest speculations. But whether this be or be not his object, it is an insult to common sense to suppose that associations of this description will be as carefully and skilfully conducted as those in which the partners are indefinitely liable for their proceedings.

It has been attempted to apologize for the non-liability system by referring to the usury laws, which permit loans to be made at any rate of interest and under a great variety of conditions. That, however, has evidently no real bearing on the matter. If A lend B a sum at 5, 10, or 15 per cent., it is the affair of the parties, and of none else. They enter into the transaction with a full knowledge of the circumstances, and believe it will be for their mutual advantage. There is, however, no limitation of risk either on the one side or the other. The business in which the loan is to be employed may not succeed, and the borrower may become bankrupt; but if so, his entire effects will be liable to the uttermost farthing for this and his other debts. He therefore has every motive to manage his business so that he may avert a catastrophe that would bring with it his inevitable ruin. But such would not be the case were B's liability limited; and it would be foolish to expect to have the conduct suited to one set of circumstances under a totally different set.

Influence of non-liability in the United States.

It would be the easiest thing imaginable, were it at all necessary, to corroborate the previous statements by illustrations drawn from the United States, where the principle of limited liability has been long established. But these must be familiar to almost all our readers. Everybody knows that, notwithstanding the peculiarly favourable circumstances under which the Americans are placed, from their free institutions, their enterprising character, the lowness of their public burdens, and the boundless extent of their fertile and unoccupied lands, bankruptcy is ten times more prevalent among them than in England. The revulsions by which we are sometimes visited, though sufficiently severe, are gentle in the extreme compared with those that periodically devastate the United States. In various instances, one of which is of very recent occurrence, every banking company in the Union has stopped payment, while great numbers have been totally destroyed. And it is the same with associations of all sorts. A spirit of over-trading, or a determination, at all hazards, to "go a-head," is universally prevalent, and bears there, as here, its legitimate harvest of bankruptcy and disaster. So much so, indeed, is this the case, and such and so violent are the convulsions referred to, that it is no exaggeration to affirm that monied fortunes and personal property are more secure in Austria and Russia than in the United States. The national character has suffered through this miserable system. Those repudiations which have so justly damaged the credit of the Americans originated in their attempting to limit their responsibilities in their public as well as in their private capacity. And it could hardly, indeed, be expected that people who may contract debts to their neighbours which they are not bound to pay should be disposed to make an exception in the case of their foreign creditors.

Limited liability injurious to the poorer as well as to the richer classes.

We sometimes hear the rather unwarrantable assertion, that, unless their liability be limited, neither the poorer nor the richer classes are generally disposed to engage in extensive partnerships! But if it really had the effect of tempting the poorer classes to engage in them, that alone would be a very sufficient reason why all associations with limited liability should be suppressed. The condition of these classes will never be improved by withdrawing their attention from the businesses to which they have been bred, and in which they are engaged, to fix it on joint-stock adventures. The spirit of gambling and speculation is already quite enough diffused, without seeking to spread its baneful influence among the lower classes. Nothing should be done which it is possible to avoid to divert their attention from the pursuits of sober persevering industry. Their surplus earnings may be far more beneficially invested in savings-banks, in loans, and in contributions to friendly societies, than in joint-stock adventures.

And while, on the one hand, it would be very wrong to tempt by immunities of any sort the labouring classes to

engage in such schemes, it is, on the other, quite superfluous in the case of their richer brethren. They are already much too prone to embark in them. Even in those businesses, the hazard of which is extreme, there is no good reason for exempting those by whom they are carried on from the fullest responsibility. If the demand for gunpowder were doubled, the supply would very shortly be increased in an equal degree. Wherever there is extra risk it is compensated by extra profits; and, practically, it is not found that the cost of gunpowder, or of any like article, is in any degree increased from capitalists being disinclined to face the hazard of its production.

Cautious men are content with moderate profits, and encounter only moderate risks; while those who are sanguine and adventurous, whether they be rich or poor, eagerly grasp at the highest profits, and to realize them do not hesitate to run the greatest hazards. Now, there is nothing surely to object to or amend in this. And yet the whole doctrine of limited responsibility proceeds on the contrary assumption—on the principle, if we may so call it, that profit and risk shall be divorced from each other; that speculators may undertake adventures, having, on the one hand, the chance of making unlimited profits if they turn out well, and on the other, of escaping, though they may ruin others, with a comparatively trifling loss if they turn out ill. In that peculiar class of cases in which it would seem at the first blush of the matter that limited responsibility would be least objectionable, it will be found to be most pernicious; for it will give an unnatural stimulus to what certainly does not require it, that is, to hazardous enterprises and desperate adventures.

On the whole, nothing but mischief can be legitimately anticipated from the establishment of partnerships with limited liability, or *en commandite*. It was not by the aid of the principles which they involve, by shirking responsibility, and evading the risks inseparable from all undertakings, that we have attained to our pre-eminence in character, in wealth, and in manufacturing and commercial industry. But are we well assured that the adoption of a contrary system will not mark the æra of our decline?

Application of limited liability to banking.

We have already seen that the limited liability system was not applied in the outset to the business of banking. But this exemption has been of short continuance, a law having been passed in the course of the present year (1858) authorizing banking companies, not issuing notes, to be established with limited liability. It was successfully alleged in defence of this measure that there should be no exception to the general rule; and that Parliament having introduced the system of limited liability into other businesses, was bound, in consistency, to extend it to banking. But if this sort of reasoning is to have any influence in such matters, it would not justify merely, but require, that the system should be extended to all companies, however small the number of partners, and even to all individuals. Why is a privilege to be conceded to ten or twelve persons, and denied to six, to four, or to one? Where, may we ask, is the justice of such a proceeding? Why should not Mr A. be permitted to limit his liability; to declare, *à priori*, that whatever debts he may contract, he shall be liable only to the extent of some L.500 or L.1000; and that it is to this "fund," and not to his estates, his factories, or his consols, that his creditors have exclusively to look? But everybody knows, or ought to know, that there is something more than mere logical etiquette to be attended to in public affairs. When a law has been enacted which affects certain businesses or certain individuals, the question, whether it should be extended to others, depends in no degree on hypothetical notions about the symmetry of legislation, but on the fact whether it is a beneficial law, and on its being fitted to promote the interests of those to whom it is proposed to extend its operation. When the cook has ascertained that a particular sauce is good for the goose, she may then, but not till then, think of applying it to the gander. But limited liability is not a sauce which is suitable for anything. It has not a single good quality to recommend it; and instead of being extended, the sphere of its operation should be contracted as much as possible. In so far, however, as banks are concerned, we incline to think that its extension to them will not have much influence either one way or other; for we cannot believe it possible, were an ordinary bank to limit its liability, that half-a-dozen individuals would be found to entrust their money to its keeping. If they did, they would well deserve to meet the fate which would be all but certain to await them—that is, to lose their entire deposits. If it attempted, as it would probably do, to allure loans by the offer of a comparatively high rate of interest, that would make its ruin more certain and immediate: and is a bait that would be swallowed by those only whose ignorance was even greater than their voracity. We therefore have little doubt that the device of limited liability will be rejected by all banking companies that have any pretensions to character, or that have any wish to possess any portion of the public confidence. It is not by vicious and inapplicable measures of this sort that joint-stock banking will be improved. What is wanted in it is a return to the old law, which enabled the creditors of insolvent banks to seek redress by execution against such stockholders as they pleased to prosecute; to evince a determination to make all directors who act either dishonestly or with gross carelessness liable for the consequences; and to facilitate the proceedings in bankruptcy. This is all that is required to be done in respect of these matters in as far as banks are concerned. And a return to the old system of unlimited liability, except in special routine cases, which may be left to the decision of the Board of Trade, with the like leave to proceed against individuals, and the publication of their names, would obviate the principal objections to the present law in as far as it affects joint-stock companies. (J. R. M.)

PASCAL, Blaise,[1] one of the brightest names in the annals, not only of France, but of the human race, was born at Clermont in Auvergne, in the year 1623. He was not forty when he died. But the achievements which he crowded into his brief span of life, and which have made his name famous to all generations, may well make the world say with Corneille, "A peine a-t' il vécu; quel nom il a laissé?" From the earliest childhood Pascal exhibited most prococious proofs of inventive genius, especially in the department of mathematics. If we may believe a universally-received tradition, he had been purposely kept in ignorance of geometry, lest his propensity in that direction should interfere with the prosecution of other branches of knowledge. But in vain: his self-prompted genius, so it is said, discovered for itself the elementary truths of the forbidden science; and at twelve years of age he was surprised by his father in the act of demonstrating on the pavement of an old hall where he used to play, and with the

---

[1] This biographical sketch is chiefly taken from the essay on the Life, Genius, and Writings of Pascal, inserted in the *Edinburgh Review* for January 1847. Some few additional paragraphs have been inserted, and the matter in general has been distributed differently, as well as abridged. For a fuller discussion of several important questions than would be possible in the limits of an article like the present, the reader is referred to the essay above mentioned.

help of a rude diagram, traced by a piece of charcoal, a proposition which corresponded to the thirty-second of the first book of Euclid. At the age of sixteen he composed a little tractate on the conic sections, which provoked the incredulity and admiration of Descartes. At nineteen, he invented his celebrated arithmetical machine; at the age of six-and-twenty, he had composed the greater part of his mathematical works, and made those brilliant experiments in hydrostatics and pneumatics which have associated his name with those of Torricelli and Boyle, and stamped him as one of the first philosophers of his age.

Strange to say, he then suddenly renounced the splendid career to which his genius so unequivocally invited him, and abandoned himself to totally different studies. In part this was attributable to the strong religious impulse given to his character at this period,—rendered deeper no doubt by early experience in the school of affliction; for from the age of eighteen he was a perpetual sufferer, and in 1647, when only in his twenty-fourth year, was visited by a slight attack of paralysis. His ill health seems mainly to have been occasioned by his devotion to study; his mind, in fact, consumed his body. The impulse, however, which finally drove him from the world, and turned him into a religious recluse, seems to have been aided by incidents which occurred a few years later. It is said that a hopeless attachment (so M. Faugère plausibly conjectures) to the sister of his accomplished friend and patron the Duc de Roannes, but which Pascal, from timidity, never avowed to the object of it, increased his constitutional melancholy; but however this may be, a far deeper effect was produced by an escape from a frightful death in the year 1654. He was in a coach and four with some friends, and, in crossing the Seine over a bridge, part of the parapet of which was thrown down, the leaders took fright and leaped into the water; their weight as they fell happily broke the traces, and left the carriage free. But Pascal's nervous system received a shock which it seems never to have recovered; and he was often haunted with the thought that on the left side of him—that on which the danger threatened on this occasion—there yawned a deep chasm; nor could he, it is said, sit at ease unless fortified on that side by the sensation of some solid obstacle, though, strange to say, an empty chair would answer the purpose.

So complete was his abandonment of science that he never returned to it but on one memorable occasion, and then only for a short time,—namely, when he solved the remarkable problems relating to the Cycloid. The accounts which have been transmitted to us by his sister of the manner in which these investigations were suggested and completed—accounts which are authenticated by a letter of his own to Fermat—strongly impress us with the vigour and brilliancy of his genius. We are assured that after long abandonment of the mathematics, his attention was directed to the curve in question by a casual train of thought suggested in one of the many nights which pain made sleepless. His inventive mind rapidly pursued the subject till he reached the brilliant results recorded in his own writings; and in the brief space of eight days these difficult investigations were completed. Partly in compliance with the fashion of the age, and partly from the solicitation of his friend the Duc de Roannes, he concealed for a time the results at which he had arrived, and offered the problems for solution to all the mathematicians of Europe, with a first and second prize to successful candidates. If no solution were offered in three months, Pascal promised to publish his own. Several were forwarded, but as none, in the estimation of the judges, completely fulfilled the conditions of the challenge, Pascal redeemed his pledge, under the name of Amos Dettonville, an anagram of Louis de Montalte, the famous pseudonym under which the *Provincial Letters* had appeared. This was in 1658–9, when he was thirty-six years of age. With this brief exception, then, and which occurs quite as a parenthesis in his history, Pascal practically abandoned science from the age of twenty-six; yet he did not at once become a religious recluse. For some years he lived a cheerful, sometimes even a gay, though never a dissipated life, in Paris, in the centre of literary and polite society, loved and admired by a wide circle of friends, and especially by the Duc de Roannes. At length, however, under the influence of the causes before specified, his indifference to the world—perhaps we might say his disgust for it—so far increased that he sighed for solitude. This he sought and found at Port-Royal, already endeared to him as the home of his sister Jacqueline.

Here he produced his immortal *Provincial Letters;* and, when death cut short his brief career, was meditating an extensive work on the fundamental principles of religion, especially on the existence of God and the evidences of Christianity. For its completion he asked ten years of health and leisure! An outline of the work had been sometimes (and on one occasion somewhat fully) given to his friends in conversation, but no part of it was ever completed. Nothing was found after his death but detached *Thoughts* (interspersed with some on other subjects) on the principal topics appropriate to such a work. They were the stones of which the building was to have consisted, many of them unhewn, and some few such as the builder, had he lived, would no doubt have laid aside. The form in which the *Thoughts* were put together comported but too well with their fragmentary character. It appears that Pascal did not even use a common-place book; but when, after profound meditation, any thought struck him as worth recording, he hastily noted it on any scrap of paper that came to hand, often on the backs of old letters; these he strung together on a file, or tied up in bundles, and left them till better health and untroubled leisure should permit him to evoke a new creation out of this chaos. It is a wonder, therefore, that the *Pensées* of Pascal have come down to us at all. Never, surely, was so precious a freight committed to so crazy a bark. But we shall return to this subject when we come to criticize the writings of Pascal, for the literary history of the *Pensées* is not a little curious. The latter years of his life were spent in almost incessant suffering, not a little increased by the maceration and ascetic rigour to which he subjected a body but little adapted originally to sustain such severe discipline. After lingering in a long decay, through the clouds of which, however, his genius shone with undiminished radiance, even to its setting, he died at Port-Royal in 1662, at the early age of thirty-nine.

We now proceed to make a few observations on the genius and character of this great man. His was one of the rare minds, apparently adapted almost in equal measure to the successful pursuit of the most diverse departments of philosophy and science, of mathematics and physics, of metaphysics and criticism. Many have transcended him in *knowledge;* for Pascal followed the predominant law of all very inventive minds,—he was fonder of thought than of books, of meditation than of acquisition. Perhaps, also, the character of Pascal's genius was less excursive than that of some other men. But in inventiveness few have been his equals; few even in mathematics, while in moral science, the science of man, we know of nothing out of Bacon and Shakspeare that will bear comparison in depth, subtlety, and comprehensiveness with some of the *Thoughts* of Pascal. But, in another characteristic of true genius, and which, for want of another name, we must call *felicity*, scarcely any one can, in the full import of the term, be compared with him. Endowed with originality the most active and various, all that he did was with grace. Full of depth, subtlety, brilliancy, both his thoughts, and the man-

ner in which he expresses them, are also full of beauty. His just image is that of the youthful athlete of Greece, in whom was seen the perfection of physical beauty and physical strength,—in whom every muscle was developed within the just limits calculated to secure a symmetrical development of all, the largest possible amount of power and flexibility in union.

In all the manifestations of Pascal's mind this rare felicity is exuberantly displayed: in the happy methods by which he lighted on truth and pursued scientific discovery; in the selection and arrangement of topics in all his compositions; in the peculiar delicacy of his wit, so strongly contrasted with all the ordinary exhibitions of that quality with which his age was familiar; and, above all, in that indescribable elegance of expression which uniformly characterizes his finished efforts, and often his most negligent utterances, and which even time can do nothing to impair.

In his scientific writings, the traces of this felicity may be discerned almost equally in the *matter* and the *form*. In relation to the first, there is probably a little illusion practised upon us. In reading his uniformly elegant and perspicuous exposition of his own scientific discoveries, we are apt to underrate the toil and intellectual struggles by which he achieved them. We know that they were, and must have been, attended with much of both,—nay, that his shattered health was the penalty of the intensity of his studies. Still, it is hardly possible to read his expositions without having the impression that his discoveries resembled a species of inspiration, and that his mind followed out the first germinant thought to its ultimate consequences with more ease and rapidity than is usually the case. One can scarcely imagine it necessary for him to have undergone the frightful toils of Kepler, had he been led into the same track of discoveries; and, in fact, whatever illusion his ease and elegance of manner may produce, we know that, comparatively speaking, his achievements were rapidly completed. It was so with the problems on the cycloid; it was so with his discoveries in pneumatics and hydrostatics. In fact, though his *Traité de l'Equilibre des Liqueurs*, and the one *De la Pesanteur de l'Air*, were not composed till 1653, they seem to have been only another form of the treatise he promised in his *Nouvelles Expériences Touchant le Vide*, published in 1647, and of which that tract was avowedly an abridgment. Indeed, as already said, Pascal had nearly quitted these investigations before the completion of his twenty-sixth year.

There was no scientific subject which Pascal touched in which the felicity of his genius, the promptitude and brilliancy of his mind, did not shine forth. We see these qualities eminently displayed in his *Traité du Triangle Arithmétique*, in the invention and construction of his arithmetical machine, in the mode of solving the problems respecting the cycloid,—in which, while employing Cavalieri's Method of Indivisibles, he proposes to remove the principal objection which had been made to it, by conceptions which bring him within a step of the Fluxions of Newton and the Calculus of Leibnitz. The same qualities of mind are eminently displayed in the manner in which he establishes the hydrostatic paradox, and generally in the experiments detailed in the *Nouvelles Expériences*, and the other connected pieces,—most of all in the celebrated *crucial* experiment on the Puy-de-Dôme, by which he decided the cause of the suspension of the mercury in the barometrical tube. As there are few things recorded in the history of science more happily ingenious than the conception of this experiment, so never was there anything more pleasantly *naïve* than the manner in which he proposes it in his letter to M. Perier. "You doubtless see," says he, "that this experiment is decisive of the question; and that if it happen that the mercury shall stand lower at the top than at the bottom of the mountain (as I have many reasons for thinking, although all those who have meditated on this subject are of a contrary opinion), it will necessarily follow that the weight and pressure of the air are the sole cause of this suspension of the mercury, and not the *horror of a vacuum;* since it is very certain that there is much more air to press at the base than on the summit of the mountain; while, on the other hand, we surely cannot say that nature abhors a vacuum more at the bottom of a mountain than on the top of it."[1]

The usual felicity of his style is seen throughout his philosophical as well as his other works. They possess the highest merit which can belong to scientific composition. It is true that, in his purely *mathematical* writings, partly from the defective notation of his age, itself a result of the want of that higher calculus, the invention of which was reserved for Newton and Leibnitz, he is often compelled to adopt a more prolix style of demonstration than would have been subsequently necessary; but even here, and still more in all the fragments which relate to natural philosophy, his style is in striking contrast with the clumsy expression of the generality of contemporary writers. His Fragments abound in that perspicuous elegance which the French denominate by the expressive word *netteté*. The arrangement of thought and turn of expression are alike beautiful. Probably no one ever knew so well when to stay his hand.

But it is, of course, in his writings on moral and critical subjects that this felicity may be chiefly expected to appear; and here we may well say, in the eloquent language of M. Faugère, it is a "style grand sans exagération, partout rempli d'emotion et contenu; vif sans turbulence, personnel sans pédanterie et sans amour propre, superbe et modeste, tout ensemble;" or, as he elsewhere expresses it, "tellement identifié avec l'âme de l'écrivain qu'il n'est que la pensée elle même, parée de sa chaste nudité comme une statue antique." By the confession of the first French critics, the *Lettres Provinciales* did more than any other composition to fix the French language. On this point the suffrages of all the most competent judges—of Voltaire and Bossuet, D'Alembert and Condorcet—are unanimous. "Not a single word occurs," says the first, "partaking of that vicissitude to which living languages are so subject. Here, then, we may fix the epoch when our language may be said to have assumed a settled form." "The French language," says D'Alembert, "was very far from being formed, as we may judge by the greater part of the works published at that time, and of which it is impossible to endure the reading. In the *Provincial Letters* there is not a single word that has become obsolete; and that book, though written above a century ago, seems as if it had been written but yesterday." And as these Letters were the first models of French prose, so they still remain the objects of unqualified admiration. The writings of Pascal have indeed a paradoxical destiny,—flourishing in immortal youth, all that time can do is to superadd to the charms of perpetual beauty the veneration which belongs to age. His style cannot grow old.

When we reflect on the condition of the language when he appeared, this is truly wonderful. It was but partially reclaimed from barbarism; it was still an imperfect instrument of genius. He had no adequate models,—he

[1] Descartes claimed the suggestion of this brilliant experiment. But it is certain that Pascal, who was the very soul of honour, repeatedly declares that he had determined to make it from the very time he had verified Torricelli's, and only waited the opportunity of performing it. On the other hand, Descartes was jealous of the discoveries of others, and, as Leibnitz truly observes, slow to give them all the praise and admiration which were their due.

was to create them for others. Now, to seize a language in its rude state, and compel it, in spite of its hardness and intractability, to become a malleable material of thought, is the exclusive prerogative of the highest species of minds; nothing but the intense fire of genius can fuse these heterogeneous elements, and mould them into forms of beauty. As a proof, we have the fact that none but the highest genius has ever been equal to this task. Genius of less than the first order will often make improvements in the existing state of a language, and give it a perceptible impulse; but only the most creative and plastic power can at once mould a rude language into forms which cannot become obsolete,—forms which remain in perpetuity a part of the current literature, amidst all the changes of time and the caprices of fashion. Thus it required a Luther to mould the harsh German into the language of his still unrivalled translation of the Scriptures, in which, and in his vernacular compositions, he first fairly reclaimed his native language from its wild state, brought it under the yoke, and subjected it to the purposes of literature. Pascal was in a similar manner the creator of the French.

The severely pure and simple taste which reigns in Pascal's style seems, when we reflect on those faults which more or less infected universal letters, little less than a miraculous felicity. One wonders by what privilege it was that he freed himself from the contagion of universal example, and rose so superior to his age. Taste was yet almost unfelt: each writer affected extravagance of some kind or other: strained metaphor, quaint conceits, far-fetched turns of thought, unnatural constructions,—these were the vices of the day; not so much perhaps in France as in England, but to a great extent in both. From all these blemishes Pascal's style is perfectly free; he anticipated all criticism, and became a law to himself. Some of his observations, however, show that his taste was no mere instinct; they indicate how deeply he had revolved the true principles of composition. His thoughts *Sur l'Eloquence et le Style* are well worth the perusal of every writer and speaker. In one of them he profoundly says, "The very same sense is materially affected by the words that convey it. The sense receives its dignity from the words, rather than imparts it to them." In another he says, "All the false beauties that we condemn in Cicero have their admirers in crowds." And in a third he admirably depicts the prevailing vice of strained antitheses; "Those," says he, "who frame antitheses by forcing the sense are like men who make false windows for the sake of symmetry. Their rule is not to speak justly, but to make just figures." The time spent on his own compositions shows that even such felicity as his could not dispense with that toil which is an essential condition of all perfect writing,—indeed of all human excellence,—and affords one other proof of the extreme shallowness of that theory which would have us believe that, to attain success, genius alone is all-sufficient. He is said, when engaged on his *Lettres Provinciales,* to have sometimes employed twenty days upon a single letter.

Another circumstance which, as already intimated, indicates Pascal's felicity of genius, is the peculiar delicacy and refinement of his *wit.* We say its *delicacy* and *refinement;* for the mere conjunction of great wit with great aptitudes for either philosophy or poetry cannot be considered as a felicity peculiar to Pascal. It is the *character* of that wit. The conjunction of distinguished wit, in one or other of its many forms, with elevated genius, is far too common to be regarded as a peculiarity of Pascal's mind. Paradoxical as the statement may at first sight appear to those who have been accustomed to consider wisdom and wit as dwelling apart, it may be doubted whether there is any one attribute so common to the highest order of mind, whether scientific or imaginative, as wit of some kind. Plato, Bacon, and Shakspeare may be cited as examples.

The wit of Pascal appears even now exquisitely chaste and natural—attired in a truly Attic simplicity of form and expression. In one quality—that of irony—nothing appears to us to approach it, except what we find in the pages of Plato, between whom and Pascal (different and even opposite as they were) it is easy to trace a resemblance in other points besides the character of their wit. Both possessed surpassing acuteness and subtlety of genius in the department of abstract science; both delighted in exploring the depths of man's moral nature; both gazed enamoured on the ideal forms of moral sublimity and loveliness; both were characterized by eminent beauty of intellect; and both were absolute masters of the art of representing thought, each with exquisite refinement of taste, and all the graces of language. The Greek, indeed, possessed a far more opulent imagination, and often indulged in a more gorgeous style than the Frenchman; or rather Plato may be said to have been a master of all kinds of style. But his dramatic powers, in none of his dialogues, can be greater than those which Pascal has displayed in his *Provincial Letters.*

The moral aspects of Pascal's character are as inviting as those of his intellect: here, too, he was truly great. Some infirmities indeed he had, for he was no more than man. He is nevertheless one of the very few who as passionately pursue the acquisition of moral excellence as the quest after speculative truth; who practically, as well as theoretically, believe that the highest form of humanity is not intellect, but goodness. Usually it is far otherwise; there is no sort of proportion between the diligence and assiduity which men are ordinarily willing to expend on their intellectual and their moral culture. Nor is it less than an indication of something wrong about human nature, a symptom of spiritual disease, that of those three distinct orders of greatness which Pascal has so exquisitely discriminated in his *Pensées*—Power, Intellect, and Goodness—the admiration inspired by the two first should be so much greater than that inspired by the last.

Few men have ever dwelt on the ideal of moral perfection, or sought to realize its image in themselves, with more ardour than Pascal; not always, indeed (as regards the *mode*), with as much wisdom as ardour. Yet upon all the great features of his moral character one dwells with the serenest delight. Much as he is to be admired, he is yet more to be loved. His humility and simplicity, conspicuous as his genius and acquisitions, were those of a very child. The favourite of science, often crowned, as an old Greek might have said of some distinguished young hero at Olympia, with the fairest laurels of the successful mathematician and the unrivalled polemic,—making discoveries even in his youth which would have intoxicated many men to madness,—neither pride nor vanity found admission to his heart. Philosophy and science produced on him only their proper effect; and taught him, not how much he knew, but how little,—not merely what he had attained, but of how much more he was ignorant. His perfect love of truth was beautifully blended with the gentlest charity, and his contempt of fraud and sophistry never made him forget, while indignantly exposing them, the courtesies of the gentleman and the moderation of the Christian; and thus the severest raillery that probably ever fell from human lips flows on in a stream undiscoloured by one particle of malevolence, and unruffled by one expression of coarseness and bitterness. The transparency and integrity of his character not only shone conspicuous in all the transactions of his life, but seem even now to beam upon us as from an open, ingenuous countenance, in the inimitable frankness and clearness of his style. It is impossible to read the passages in his philosophical writings, in which he notices or refutes the calumnies to which he had

been exposed, and by which it was sometimes sought to defraud him of the honour of the discoveries he had made, in one instance even to cover him with the infamy of appropriating discoveries which had been made by others, without being convinced of the perfect candour and uprightness of his nature.[1] His generosity and benevolence were unbounded; so much so, indeed, as to become almost vices by excess, passing far beyond that mean in which the Stagyrite fixes the limits of all virtue. He absolutely beggared himself by his prodigal benefactions: he did what few do, mortgaged even his expectancies to charity. To all which we may add, that he bore the prolonged and excruciating sufferings of his latter years with a patience and fortitude which astonished all who witnessed them.

The failings of Pascal (for to these we must advert) were partly the result of that system of faith in which he had been educated; and which, though he did so much to expose many of the worst enormities which had attached themselves to it, still exercised considerable influence over him. It is lamentable to see such a mind as his surrendering itself to some of the most grievous extravagances of asceticism. Yet the fact cannot be denied; nor is it improbable that his life—brief, perhaps, at the longest, considering his intense study and his feeble constitution—was made more brief by these pernicious practices. We are told not only that he lived on the plainest fare, and performed the most menial offices for himself,—not only that he practised the severest abstinence and the most rigid devotions,—but that he wore beneath his clothes a girdle of iron, with sharp points affixed to it; and that whenever he found his mind disposed to wander from religious subjects, or take delight in things around him, he struck the girdle with his elbow, and forced the sharp points of iron into his side. We even see but too clearly that his views of life to a considerable extent became perverted. He cherished mistrust even of its blessings, and acted, though he meant it not, as if the very gifts of God were to be received with suspicion as the smiling tempters to ruin—the secret enemies of our well-being. He often expresses himself as though he thought, not only that suffering is necessary to the moral discipline of man, but that nothing but suffering is at present safe for him. "I can approve," he says in one place, "only of those who seek in tears for happiness." "Disease," he declares in another place, "is the natural state of Christians." It is evident that the gracious Master in whose school we all are, and whose various dispensations of goodness and severity are dictated by a wisdom greater than our own, does not think so: if he did, health would be the exception, and disease the rule.

Pascal was obviously misled, by these sentiments, into the self-imposed ascetic severities which aggravated all the sufferings of his later years. But it is at our peril that we interfere with the discipline which is provided for us. He who acts as if God had mistaken the proportions in which joy and sorrow, prosperity and adversity, should be allotted to us,—who seeks, by hair shirts, prolonged abstinence, and self-imposed penance, to render more perfect the discipline of suffering,—only enfeebles instead of invigorating his piety, and resembles one of those hypochondriacal patients—the plague and torment of physicians—who, having sought advice, and being supposed to follow it, are found not only taking their physician's well-judged prescriptions, but secretly dosing themselves in the intervals with some quackish nostrum. Thus did Pascal; and it is impossible not to see that the experiment was attended in his case with very pernicious effects.

It is indeed pitiable to read that, during his last days, his perverted notions induced him to refrain from the natural expressions of fondness and gratitude towards his sisters and attendants, lest the affection with which they regarded him should become inordinate,—lest they should transfer to an earthly creature the affection due only to the Supreme. Something, indeed, like an attempted justification of such conduct occurs in his *Pensées*—"Il est injuste qu'on s'attache à moi, quoiqu'on le fasse avec plaisir et volontairement. Je tromperais ceux à qui j'en ferais naître le désir; car je ne suis la fin de personne, et n'ai pas de quoi les satisfaire. Ne suis-je pas prêt à mourir? Et ainsi l'objet de leur attachment mourra donc. Comme je serais coupable de faire croire une fausseté, quoique je la persuadasse doucement et qu'on la crût avec plaisir, et qu'en cela on me fit plaisir; de même je suis coupable de me faire aimer." Madame Perier has cited this passage in the life of her brother as accounting for his apparent coldness to herself.[2]

It is wonderful that a mind so powerful should have been misled by a pernicious asceticism to adopt such maxims; it is still more wonderful that a heart so fond should have been able to act upon them. To restrain, even in his dying hours, expressions of tenderness towards those whom he so loved, and who so loved him; to simulate a coldness which his feelings belied; to repress the sensibilities of a grateful and confiding nature; to inflict a pang, by affected indifference, on hearts as fond as his own; here was indeed a proof of the truth upon which he so passionately meditated, the greatness and the misery of man,—of his strength and his weakness: weakness, in supposing that such perversion of all nature could ever be a dictate of duty; strength, in performing, without wincing, a task so hard. The American Indian, bearing unmoved the torture of his enemies, exhibits not, we may rest assured, greater fortitude than Pascal, when, with such a heart as his, he received in silence the last ministrations of his devoted friends, and even declined, with cold and averted eye, the assiduities of their zealous love. That same melancholy temperament which, united with a pernicious asceticism, made him turn his gaze even from innocent pleasure, and suspect a serpent lurking in every form of it, also gave to his *representations* of the depravity of our nature an undue intensity and Rembrandt-like depth of colouring. His mode of expression is often such that, were it not for what we otherwise know of his character, it might be mistaken for an indication of misanthropy. With this vice, accordingly, Voltaire does not hesitate to tax him. "Ce fameux écrivain, misanthrope sublime." Nothing can be more unjust. As to the *substance* of what Pascal has said of human frailty and infirmity, most of it is at once verified by the appeal to individual consciousness; and as to the *manner*, we are not to forget that he everywhere dwells as much upon the greatness as upon the misery of man. "It is the ruined archangel," says Hallam, with equal justness and beauty, "that Pascal delights to paint." It is equally evident that he is habitually inspired by a desire to lead man to truth and happiness; nor is there anything more affecting than the passage with which he closes one of his expostulations with Infidelity, and which M. Cousin finely characterizes as "une citation glorieuse à Pascal." "This argument," you say, "delights me. If this argument

---

[1] See more particularly his letters to Father Noel, M. Le Pailleur, and M. De Ribeyre.

[2] The passage of Madame Perier is deeply affecting. "Meanwhile, as I was wholly a stranger to his sentiments on this point, I was quite surprised and discouraged at the rebuffs he would give me upon certain occasions. I told my sister of it, and not without complaining that my brother was unkind. and did not love me; and that it looked to me as if I put him in pain, even at the very moment I was studying to please him, and striving to perform the most affectionate offices for him in his illness." (Madame Perier's *Memoirs of Pascal*)

pleases you, and appears strong, know that it proceeds from one who, both before and after it, fell on his knees before that infinite and invisible Being to whom he has subjected his whole soul, to pray that He would also subject *you* to Himself, for your good and for His glory; and that thus omnipotence might give efficacy to his feebleness."

In addition to this, it must be said that, in his most bitter reflections, this truly humble man is thinking as much of himself as of others, and regards Blaise Pascal as but a type of the race whose degeneracy he mourns. His most bitter sarcasms often terminate with a special application to the writer. Thus he says, "Vanity is so rooted in the heart of man, that a common soldier or scullion will boast of himself, and will have his admirers. It is the same with the philosophers. Those who write would fain have the fame of writing well; and those who read it, would have the glory of having read it; *and I, who am writing, probably feel the same desire, and not less those who shall read it.*"

It is true, indeed, that some of his reflections are as caustic and bitter as those of Rochefoucauld himself. For example:—"Curiosity is but vanity. Often we wish to know more, only that we may talk of it. People would never traverse the sea if they were never to speak of it, for the mere pleasure of seeing, without the hope of ever telling what they have seen." And again:—"Man is so constituted that, by merely telling him he is a fool, he will at length believe it; and if he tells himself so, he will constrain himself to believe it. For man holds an internal intercourse with himself which ought to be well regulated, since even here 'evil communications corrupt good manners.'"—"I lay it down as a fact, that if all men knew what they say of one another, there would not be four friends in the world. This appears by the quarrels which are sometimes caused by indiscreet reports."

Still, as it is the motive which gives complexion to all our moral actions, so Pascal's bitter wisdom, or even his unjust satire, is something very different from misanthropy. With what noble eloquence—with what deep sympathy with humanity—does he rebuke the levity of those infidels who tell us, as if it were matter of triumph, that we are the inhabitants of "a fatherless and forsaken world," and who talk as if their vaunted demonstration of the vanity of our immortal hopes gave them a peculiar title to our gratitude and admiration! "What advantage is it to us to hear a man saying that he has thrown off the yoke; that he does not think there is any God who watches over his actions; that he considers himself as the sole judge of his conduct, and that he is accountable to none but himself? Does he imagine that we shall hereafter repose special confidence in him, and expect from him consolation, advice, succour, in the exigencies of life? Do such men imagine it is any matter of delight to us to hear that they hold that our soul is but a little vapour or smoke, and that they can tell us this in an assured and self-sufficient tone of voice? Is this, then, a thing to say with gaiety? Is it not rather a thing to be said with tears, as the saddest thing in the world?"

We now proceed to make a few observations on the principal writings of Pascal. The one on which his fame, as a great thinker, chiefly rests, fragmentary as it is, is the *Pensées*. We have alluded to the literary history of this work as highly curious. The thoughts were written, as already said, on any scraps of paper that came to hand; these were strung on a file, and left till health and leisure should enable the author to develop and arrange them.

Health and leisure never came. But it was not this only which has rendered the work so fragmentary. Many of the thoughts are themselves only half developed; others, as given us in the literal copy of M. Faugère's admirable edition, break off in the middle of a sentence, even of a word. Some casual interruption—frequently, no doubt, some paroxysm of pain, to which the great author in his latter years was incessantly subject—broke the thread of thought, and left the web imperfect for ever.

On the imperfect sentences and half-written words, which are now given in the volumes of M. Faugère, we look with something like the feelings with which we pore on some half-defaced inscription on an ancient monument,—with a strange commixture of curiosity and veneration; and, whilst we wonder what the unfinished sentences may mean, mourn over the malicious accident which has perhaps converted what might have been aphorisms of profoundest importance into a series of incoherent ciphers. One of the last things, assuredly, which we should think of doing with such fragments would be to attempt to alter them in any way; least of all, to supplement them, and to divine and publish Pascal's meaning. There have been learned men who have given us supplements to the lost pieces of some ancient historians; erudite Freinsheimiuses who hand us a huge bale of indifferent Latin, and beg us only to think it Livy's lost *Decades*. But what man would venture to supplement Pascal? Only such, it may be supposed, as would feel no scruple in scouring an antique medal; or a successor to those monks who obliterated manuscript pieces of Cicero that they might inscribe them with some edifying legend. But more noted people were scarcely more scrupulous in the case of Pascal. His friends decided that the fragments which he had left behind him, imperfect as they were, were far too valuable to be consigned to oblivion; and, so far, all the world will agree with them. If, further, they had selected whatever appeared in any degree coherent, and printed these, *verbatim et literatim*, in the best order they could devise, none would have censured, and all would have thanked them. But they did much more than this, or rather they did both much more and much less. They deemed it not sufficient to give Pascal's remains with the statement that they were but fragments; that many of the thoughts were very imperfectly developed; that none of them had the advantag of the author's revision,—apologies with which the world would have been satisfied; but they ventured upon mutilations and alterations of a most unwarrantable description. In innumerable instances they changed words and phrases; in many others they left out whole paragraphs, and put a sentence or two of their own in the place of them; they supplemented what they deemed imperfect by an exordium or conclusion, without any indication as to what were the respective ventures in this rare species of literary copartnery. It must have been odd to see this committee of critics sitting in judgment on Pascal's style, and deliberating with what alterations, additions, and expurgations it would be safe to permit the author of the *Provincial Letters* to appear in public. Arnauld, Nicole, and the Duc de Roannes were certainly no ordinary men; but they were no more capable of divining the thoughts which Pascal had not expressed, or of improving the style where he had expressed them, than of completing a sketch of Raphael.

It appears that, large as was the editorial discretion assumed, they had contemplated an enterprise still more audacious,—nothing less than that of completing the work which Pascal had projected, partly out of the materials which he had left, and partly from what their own ingenuity might supply. It even appears that they had actually commenced this heterogeneous structure; and an amusing account has been left by M. Perier of the progress the builders of this Babel had made, and the reasons for abandoning the design. "At last," says he, "it was resolved to reject the plan, because it was felt to be almost impossible thoroughly to enter into the thoughts and plan of the author, and, above all, of an author who was no more; and because it would not have been the work of M. Pascal, but a work altogether different—*un ouvrage tout différent.*" Very different indeed!

If this naïve expression had been intended for irony, it would have been almost worthy of Pascal himself.

Subsequent editors took similar liberties, if not so flagrant. While the original editors left out many passages from fear of the Jesuits, Condorcet, in his edition, omitted many of the most devout sentiments and expressions, under the influence of a very different feeling. Infidelity, as well as superstition, has its bigots, who would be well pleased to have their *index expurgatorius* also.

It had been long felt that no trustworthy edition of Pascal's *Thoughts* had been published—that nobody knew precisely what was his, and what was not. M. Cousin, in his valuable *Rapport*, demonstrated the necessity of an entirely new edition, founded upon a diligent collation of the original manuscripts; and this task M. Faugère performed with incredible industry. We must refer the reader to his interesting Introduction for proof of this statement. There the editor has given the details of his labours. Suffice it here to say, that every accessible source of information was carefully ransacked; every fragment of manuscript, whether in Pascal's own hand, or in that of members of his family, was diligently examined; and every page offers indications of minute attention, even to the most trivial verbal differences. Speaking of the autograph manuscript preserved in the Royal Library at Paris,—a folio into which the original loose leaves are pasted, or, when written on both sides, carefully *let into* the page ("*encadrès*"),—he says, "We have read, or rather studied, this manuscript page by page, line by line, syllable by syllable, from the beginning to the end, and, with the exception of some words which are illegible, it has passed entire into the present edition." As the public, in the former editions, did not exactly know what was Pascal's and what was not, M. Faugère has been compelled to do what, under other circumstances, would have been undesirable, and, indeed, hardly just; what, indeed, any author of reputation would vehemently protest against in his own case. He has been obliged to give every fragment, however imperfect, *verbatim;* and the extracts, as we have already said, often terminate in the middle of a sentence, sometimes even of a word. M. Vinet justly observes in relation to this feature of M. Faugère's labours, that Pascal himself would hardly have been satisfied with "either his old editors or the new." At the same time, it must be confessed that, apart from this circumstance, it is deeply interesting to contemplate the first rude forms of profound or brilliant thoughts as they presented themselves to the ardent mind of Pascal. As M. Vinet says, "we are taken into the great sculptor's studio, and behold him at work chisel in hand."

It is impossible to determine, from the undeveloped character of these *Thoughts*, the precise form of the work Pascal contemplated; all we are told is, that it was to have treated of the primary truths of all religion, and of the evidences of Christianity. It is clear that about half the *Thoughts* which relate to theology at all have reference to the former, and form by far the profoundest portion.

In Pascal's day, however, both classes of subjects might have been naturally included in one work. The great deistical controversies of Europe had not yet commenced, and there had been little reason to discriminate very nicely the limits of the two investigations. Pascal himself could hardly have anticipated the diversified forms which the subject of the evidences of Christianity alone would assume; so diversified, indeed, that they are probably insusceptible, from their variety, of being fully exhibited by one mind, or consequently in one volume. The evidences of Christianity almost form a science of themselves.

Fragmentary as the *Pensées* are, it is easy to see, both from their general tenor and from the character of the author's mind, where the strength of such a work would be. His proofs of the truths of natural religion would have been drawn from within rather than from without; and his proofs of the truth of Christianity from its internal rather than external evidences—including in this term "internal" not only the adaptation of the doctrines revealed, to man's moral nature, but whatsoever indications the fabric of Scripture itself may afford of the divinity of its origin.—It is evident that he had revolved all these topics profoundly. None had explored more diligently the abyss of man's moral nature, or mused more deeply upon the "greatness and misery of man," or on the "contrarieties" which characterize him, or on the remedies for his infirmities and corruptions. And there are few, even since his time, who seem to have appreciated more fully the evidences of Christianity arising from indications of truth in the genius, structure, and style of the Scriptures; or from the difficulties, not to say impossibilities, of supposing *such* a fiction as Christianity the probable product of any human artifice, much less of such an age, country, and (above all) such men as the problem limits us to. In one passage he gives expression to a thought very similar to that which suggested the *Horæ Paulinæ*. He says, "The style of the gospel is admirable in many respects, and, amongst others, in this, that there is not a single invective against the murderers and enemies of Jesus Christ. . . . . If the modesty of the evangelical historians had been affected, and, in common with so many other traits of so beautiful a character, had been affected only that it might be observed; then, if they had not ventured to advert to it themselves, they would not have failed to get their friends to remark it to their advantage. But as they acted in this way without affectation, and from a principle altogether disinterested, they never provided any one to make such a criticism. *And, in my judgment, there are many points of this kind which have never been noticed hitherto;* and this testifies to the simplicity with which the thing was done."[1]

He has also, with characteristic comprehensiveness, condensed into a single paragraph the substance of the celebrated volume of *Bampton Lectures* on the contrasts between Mohammedanism and Christianity. "Mahomet founded his system on slaughter; Jesus Christ by exposing his disciples to death: Mahomet by forbidding to read; the apostles by commanding it. In a word, so opposite is the plan of one from that of the other, that if Mahomet took the way to succeed according to human calculation, Jesus Christ certainly took the way to fail; and instead of arguing that, since Mahomet succeeded, Jesus Christ might also succeed, we ought rather to say, that since Mahomet succeeded, it is impossible but that Jesus Christ should fail"

On the subject of the external evidences we doubt whether he would have been equally successful, partly because the spirit of accurate historic investigation had not yet been developed, and partly from the character of his own mind. On the subject of miracles, too, he scarcely seems to have worked his conceptions clear; and in relation to that of prophecy, he was evidently often inclined to lay undue stress on analogies between events recorded in the Old Testament and others recorded in the New, where Scripture itself is silent as to any connection between them; —analogies in some cases as fanciful as any of those in which the fathers saw so many types and prefigurations of undeveloped truths.

From certain passages in the *Pensées*, a vehement charge of scepticism has been preferred by M. Cousin, from which, says that writer, Pascal sought refuge in a voluntarily blind credulity. "Le fond même de l'âme de Pascal est un scepticisme universel, contre lequel il ne trouve d'asîle que dans une foi *volontairement aveugle.*"

[1] Tom. ii., p. 370.

These are certainly charges which, without the gravest and most decisive proof, ought not to be preferred against any man, much less against one possessing so clear and powerful an intellect as Pascal. It is, in fact, the most degrading picture which can be presented of any mind; for what weakness can be more pitiable, or what inconsistency more gross, than that of a man who, by a mere act of will—if indeed such a condition of mind be conceivable—surrenders himself to the belief of the most stupendous doctrines, while he at the same time acknowledges that he has no proof whatever of their certainty?

It appears to us that M. Cousin has forgotten that Pascal by no means denies that there is sufficient evidence of the many great principles to which scepticism objects; he only maintains that we do not arrive at them by *demonstration*. He has powerfully vindicated the certainty of those intuitive principles which are not ascertained by reasoning, but are presupposed in every exercise of reasoning. Let us hear him: "The only strong point," says he, "of the dogmatists is, that we cannot, consistently with honesty and sincerity, doubt our own intuitive principles. . . . . . We know the truth, not only by reasoning, but by feeling, and by a vivid and luminous power of direct comprehension; and it is by this last faculty that we discern first principles. It is vain for reasoning, which has no share in discovering these principles, to attempt subverting them. . . . . . The Pyrrhonists who attempt this must try in vain. . . . . . The knowledge of first principles—as the ideas of space, time, motion, number, matter—is as unequivocally certain as any that reasoning imparts."

But let us hear him still more expressly on the subject of Pyrrhonism: "Here, then, is open war proclaimed among men. Each must take a side; must necessarily range himself with the Pyrrhonists or the dogmatists—for he who would think to remain neuter is a Pyrrhonist *par excellence*. He who is not against them is for them. What, then, must a person do in this alternative? Shall he doubt of everything? Shall he doubt that he is awake, or that he is pinched or burned? Shall he doubt that he doubts? Shall he doubt that he is? We cannot get so far as this; and I hold it to be a fact, that there never has been an absolute and perfect Pyrrhonist." M. Cousin must suppose Pascal to have made an exception in favour of himself, if it be indeed true that he was an universal sceptic. It appears to us that M. Cousin has not sufficiently reflected that, in those cases in which conclusions truly involve processes of reasoning, Pascal does not deny that the preponderance of proof rests with the truths he believes, though he denies the demonstrative nature of that proof; and he applies this with perfect fairness to the evidences of Christianity as well as to the truths of natural theology. "There is light enough," says he, "for those whose sincere wish is to see, and darkness enough to confound those of an opposite disposition." Of Christianity he says, "It is impossible to see all the proofs of this religion combined in one view without feeling that they have a force which no reasonable man can withstand."

It is not without reason that M. Faugère says, in reference to the charge of scepticism urged against Pascal, "Faith and reason may equally claim him. If they sometimes appear to clash in his mind, it is because he wanted time, not only to finish the work on which he was engaged, but even to complete that internal revision (son œuvre intérieure) which is a kind of second creation of genius; and to unite into one harmonious whole the diverse elements of his thoughts. Amongst the inedited fragments of Pascal we find these remarkable lines:—'Il faut avoir ces trois qualités; Pyrrhonien, géomètre, Chrétien soumis; et elles s'accordent et se temperent en doutant où il faut, en assurant où il faut, en se soummettant où il faut.' These bold words comprise the entire history of Pascal, and express in brief the state of his mind." But it is impossible in the limits of this article to enter with the requisite fullness into the question of Pascal's imputed scepticism. The subject will be found fully treated in the essay of which this article is an abridgment; in M. Faugère's admirable Introduction to his edition of the *Pensées;* and in some very acute papers of M. Vinet, first collected and published in 1848, under the title *Etudes de Blaise Pascal;* especially in those *Sur le Pyrrhonisme de Pascal*, and *Du Livre de M. Cousin sur les Pensées*.

If the *Pensées* are the most profound, the *Lettres Provinciales* are the most brilliant of Pascal's works, and among the very few which, though turning on local and transient controversy, are so instinct with genius, so beautiful in thought and style, as to command the attention of all time.

Nothing could be apter for the purpose—that of throwing into strong light the monstrous errors of the system he opposed—than the machinery the author has selected. The affected ignorance and *naïveté* of M. Montalte, seeking information respecting the theological disputes of the age, and especially the doctrines of the Jesuits; the frankness of the worthy Jesuit father, of whom he asks instruction, and who, in the boundless admiration of his order, and the hope of making a convert, details without hesitation, or rather with triumph, the admirable contrivances by which their casuists had inverted every principle of morals and eluded all the obligations of Christianity; the ironical compliments of the supposed novice, intermingled with objections and slightly-expressed doubts,—all delivered with an air of modest ingenuousness which humbly covets further light; the acute simplicity with which he involves the worthy father in the most perplexing dilemmas; the expressions of unsophisticated astonishment, which but prompt his stolid guide eagerly to make good every assertion by a proper array of authorities,—a device which, as Pascal has used it, converts what would have been in other hands only a dull catalogue of citations into a source of perpetual amusement; the droll consequences which, with infinite affectation of simplicity, he draws from the Jesuit's doctrines; the logical exigencies into which the latter is thrown in the attempt to obviate them;—all these things, managed as only Pascal could have managed them, render the book as amusing as any novel. The form of letters enables him at the same time to intersperse, amidst the conversations they record, the most eloquent and glowing invectives against the doctrines he exposes. Voltaire's well-known panegyric does not exceed the truth, that Molière's best comedies do not excel them in wit, nor the compositions of Bossuet in sublimity. "This work," says D'Alembert, "is so much the more admirable, as Pascal, in composing it, seems to have *theologized* two things which seem not made for the theology of that time—language and pleasantry."

The success of the work is well known. By his inimitable pleasantry Pascal succeeded in making even the dullest matters of scholastic theology and Jesuitical casuistry as attractive to the people as a comedy; and by his little volume did more to render the formidable society the contempt of Europe than was ever done by all its other enemies put together. The Jesuits had nothing for it but to inveigh against the letters as "the immortal liars" (*les mênteurs immortelles*).[1]

Of the scientific writings of Pascal we have already spoken. (H. R.)

[1] To the charge of having garbled citations and tampered with evidence, in order to produce an unfair impression against the society (practices utterly abhorrent to all Pascal's habits of mind and dispositions of heart), he replies, with the characteristic boldness and

Pascal I. (Pope) succeeded Stephen IV. in the pontifical chair in 817, and died in 824.

Pascal II. (Pope), whose real name was *Ranieri*, was a monk of the order of Cluni, and succeeded Urban II. in 1099. An inveterate struggle with the occupants of the imperial throne, regarding investitures, extended over the whole of his pontificate. He began the contest in 1102 by renewing the decrees of his predecessors on that subject, and by excommunicating the Emperor Henry IV. He then encouraged the son of that monarch to raise the standard of revolt, and to supplant his father in the throne. Under the new emperor, Henry V., the controversy only assumed a more serious aspect. The emperor refused to give up his right of investiture to the Pope. The Pope threatened to withhold the ceremony of coronation from the emperor. In 1110 the emperor advanced into Italy at the head of a large army, seized upon the person of the Pope, and consigned him to bondage. For more than two months the Pope continued obstinate, and was only induced by the entreaties of his friends to crown the emperor, and yield the point of dispute. Yet the controversy thus settled was soon started again by the synods and councils of the church. They recalled the concession that had been forcibly extracted by the emperor, and renewed their claim to the right of investiture. In this manner they brought the two great potentates once more into the field against each other. Henry V. led an army towards Rome in 1116, and Pascal retreated to Benevento. The former in course of time retired from the city; and the latter, returning during the absence of his adversary, was actively engaged in preparing war when he was cut off by disease in 1118.

PASCO, or Cerro di Pasco, a town of Peru, capital of the department of Junin, stands in an irregular hollow in the elevated plain of Bonbon, 140 miles N.E. of Lima. It is meanly and irregularly built on uneven ground, the houses being for the most part low and wretched, and generally thatched. The ground on which it is built abounds in silver ore, and is almost honeycombed by the mines, many of which open in the interior of the houses. These silver mines occupy a space about 15 miles broad, from E. to W.; but it is only the most valuable of them that are now worked. Coal is also found in the vicinity. As the surrounding country is very barren, most of the provisions have to be brought to Pasco from a distance. This town is the highest permanently-inhabited spot in America, and probably also in the whole world. Its elevation is stated at 14,280 feet above the level of the sea. The population varies at different periods from 7000 to 18,000, according to the season of the year and the state of the mines.

PASCUARO, or Patzcuaro, a town of Mexico, state of Mechoacan, stands on the S.E. shore of the Lake of Pascuaro, 30 miles S.W. of Valladolid. In the neighbourhood are copper mines; and at some distance the best sugar plantations in the state. Pop. 6000.

PAS-DE-CALAIS, a department of France, lying between 50. and 51. N. Lat., 1. 35. and 3. 10. E. Long. It is bounded on the N. by the Strait of Dover, N.E. and E. by the department of Nord, S. by that of Somme, and W. by the English Channel; length, from N.W. to S.E., about 86 miles; average breadth, 33 miles; area, 2561 square miles. The country is traversed from N.W. to S.E. by a low chain of hills, from which the ground slopes gradually down on either side. The highest elevation of these hills does not exceed 327 feet; and the two slopes are scarcely to be distinguished from each other. These heights form the watershed of the rivers of the department —the Lys, the Scarpe, the Sensée, and the Aa, flowing down the N.E. slope,—the first three into the Escaut, and the last into the sea; while the Authie, the Canche, the Liane, and the Slack traverse the S.W. slope, and fall into the English Channel. The valleys of these rivers are separated by small spurs diverging from the main ridge of hills. Most of the streams are navigable for some distance, either naturally or by means of canals. Those on the north flow sluggishly through an almost flat region; and during the whole of the winter they form extensive marshes, which deposit a large quantity of alluvial soil, and increase the fertility of the country. The only promontory on the coast is Cape Grinez, between Calais and Boulogne, where the range of hills terminates in a series of chalk cliffs similar to those of Dover, on the opposite side of the Channel, and extending several miles on each side of the cape. The rest of the coast is in general low, and bordered by sandy and barren downs, having an average breadth of about two miles, and an entire area of 44,000 acres, and presenting a very bleak aspect. Along the coast-line, which is about 80 miles in length, the only good harbours are those of Calais and Boulogne. These are formed by artificial piers, and are capable of receiving large vessels; while the others can only be approached by fishing-boats. The constant accumulation of sand has destroyed several harbours that formerly existed here; and even those that still exist are in some danger of being likewise filled up.

In geological structure, the country for the most part belongs to the chalk formation. Iron and coal are found in small quantities, and several mines are wrought. Marble, limestone, quartz, rock-crystal, and other minerals, are also obtained. There are several Artesian wells in the department. These were first sunk here upwards of a century ago, and derived their name from the old province of Artois, to which this country then belonged. Richness, rather than picturesque beauty, is the prevailing aspect of the country; tracts of well-cultivated ground alternate with extensive meadows and pasturages. The country is marshy in many places; and towards the north, the low and flat ground near the coast has, as in Holland, to be defended by dykes from the incursions of the sea. The soil is very fertile, especially for corn; the farms are large, and agriculture is in an advanced state. In its variable climate, Pas-de-Calais resembles the south-western parts of England. The winters are long and rainy, and the climate in general cold, damp, and in some places not very healthy. Corn, pulse, potatoes, beet-root, hops, flax, and hemp are the principal crops raised; and a small part of the country is occupied by woods and orchards. The live stock reared here are generally of inferior breeds; but there are estimated to be in the department 80,000 horses, 180,000 horned cattle, 300,000 sheep, 7000 goats, 140,000 pigs, &c. The sea near the coast abounds in fish; and hence affords employment to a large number of the inhabitants. Manufacturing industry is actively and extensively carried on. It is cal-

frankness of his nature,—"I was asked if I repented of having written *Les Provinciales?* I reply that, far from having repented, if I had to write them now, I would write yet more strongly. . . . I was asked why I had employed a pleasant, jocose, and diverting style. I reply that, if I had written in a dogmatical style, it would have been only the learned who would have read, and they would have had no necessity to do it, being at least as well acquainted with the subject as myself; thus I thought it a duty to write so as to be comprehended by women and men of the world, that they might know the danger of those maxims and propositions which were then universally propagated, and of which they permitted themselves to be so easily persuaded. I was asked, lastly, if I had myself read all the books I have cited. I answer, No; for in that case it would have been necessary to have passed my life in reading very bad books; but I had read through the whole of Escobar twice, and, for the others, I caused them to be read by my friends. But I have never used a single passage without having myself read it in the book cited, or without having examined the subject on which it is adduced, or without having read both what precedes and what follows it, in order that I might not run the risk of quoting what was, in fact, an objection, for a reply to it, which would have been censurable and unjust."

culated that there are 700 manufactories, employing 25,000 hands, and producing annually goods to the value of L.1,920,000. The most important of the articles manufactured are,—beet-root sugar, soap, oils, cotton and woollen fabrics, linen, hosiery, and lace. Paper-mills, foundries, glass-works, potteries, tanneries, distilleries, and breweries are also in operation. The chief articles of export are,—corn, flour, sugar, oils, marble, building-stone, timber, and manufactured articles. There is a considerable coasting trade in corn and other rural produce; and the foreign commerce is chiefly carried on with England. Communication is kept up by steamers between the ports of this department and London, Dover, and Folkestone; and there is a submarine telegraph cable between Dover and Calais. The means of internal communication are furnished by three railways, extending over 88 miles, besides numerous roads, rivers, and canals. Pas-de-Calais contains a school of medicine at Arras, an academy, four colleges, a normal school, and 1220 elementary schools. It forms the diocese of Arras; and contains 6 primary courts and 4 courts of commerce. The capital is Arras; and the department is divided into arrondissements as follows:—

	Cantons.	Communes.	Pop. (1856).
Arras	10	211	169,123
Bethune	8	142	139,844
Saint-Omer	7	118	109,624
Saint-Pol	6	193	79,928
Boulogne	6	100	138,557
Montreuil	6	139	75,770
Total	43	903	712,846

PASEWALK, a town of Prussia, in the government of Stettin, on the Ucker, 27 miles W. by N. of Stettin. It is surrounded by walls; and has a court of law, churches, hospitals, and several breweries. The town is ancient, and once belonged to the Hanseatic League. Some trade is still carried on. Pop. 7217.

PASIGRAPHY (from πᾶς, *all*, and γράφω, *I write*), the imaginary art of writing so as to be universally understood by all nations of the earth. The idea of establishing such a language is deemed by many extremely fanciful, whilst the practicability of it is as strenuously contended for by others. Hints respecting such an universal language are to be met with in the writings of many eminent philosophers; but the attempt has signally failed, even in the hands of Leibnitz, Kircher, Becher, and Wilkins. Kant is of opinion, however, that such a pasigraphy falls within the limits of possibility; nay, he even prognosticates that it will certainly be established at some future period.

PASIPHAË. See MINOS.

PASKIEWITCH, IVAN FREDOROVITCH, Field-Marshal, Prince of Warsaw, Viceroy of Poland, and General-in-Chief of the Russian army, was born at Pultowa on the 12th May 1782, and was appointed at an early age aide-de-camp to the Emperor Paul. The first part of his career was one continued series of arduous campaigns and hot engagements. He began service in the terrible field of Austerlitz in 1805. Then he served from 1807 to 1812 in the army which acted against Turkey. No sooner was that expedition ended than the war with France involved him in the very thick of the most desperate of modern struggles. He fought at the battles of Dachkofka, Soultanofka, Smolensk, and Moskwa, in 1812; at the battles of Kulm, Dresden, and Leipsic, in 1813; and at the battle of Arcis-sur-Aube, in 1814. Out of that long course of deadly strife fortune brought Paskiewitch with safety and honour. She was reserving him for more successful achievements. Appointed to the command of the army of the Caucasus, he won a diamond-mounted sword by his victory at Elizavetopol in 1826, the surname of Erivansky by his storming of Erivan in 1827, and the dignity of field-marshal by his capture of Erzeroum in 1829. Entrusted in 1831 with the suppression of the revolt in Poland, he dispersed the Poles, carried their capital, and was rewarded with the titles of Prince of Warsaw and Viceroy of Poland. Sent also in 1849 to assist Austria in crushing the Hungarians, he was soon able to write home to the emperor in these words: "Hungary is at your feet." Success, however, deserted Paskiewitch at last. He was repulsed by the Turks at Silistria in 1854, and received a contusion at the same time which compelled him to retire from service, and eventually caused his death on the 29th January 1856.

PASQUIN, a mutilated statue at Rome, in a corner of the palace of the Ursini. It took its name from a cobbler of that city called *Pasquino*, famous for his sneers and gibes, and who diverted himself by telling facetious and satirical stories to those who frequented his stall, as well as by cracking his jokes upon all passers-by. The witty sayings of the cobbler came to be called *pasquinate* (hence *pasquinade*), a term subsequently applied by the Romans to all kinds of humorous epigrams and satirical lampoons. These lampoons, which attacked persons in high station, were frequently fixed by night at or near the mutilated statue alluded to, which, from that circumstance, came to be called *Pasquino*, after the defunct cobbler.

PASS, or PASSADE. See FENCING.

PASSAGE, a town of Ireland, county of Cork, on the W. side of Cork harbour, about 5 miles S.S.E. of the town of Cork. It has an Established, a Methodist, and a Roman Catholic church, and several schools. The place is much frequented as a watering-place; and has many handsome villas in the neighbourhood. There is a good harbour; and vessels that are too large to ascend to Cork unload their cargoes here. Passage has also dockyards, and is connected with Cork by a railway. Pop. 2857.

PASSAMAQUODDY BAY, an inlet of the Atlantic Ocean, on the borders of New Brunswick and the state of Maine. It extends into the land for the distance of 12 miles, and is about 6 miles broad at its mouth. It affords an excellent harbour for the largest vessels, and is never obstructed by ice. It contains several islands; and the waters abound in fish of various kinds.

PASSANT. See HERALDRY.

PASSAU, a town of Bavaria, circle of Lower Bavaria, stands at the confluence of the Danube and the Inn, 91 miles E.N.E. of Munich. Its position at the junction of these broad streams, and shut in by lofty and steep mountains, is extremely grand and picturesque, although the buildings are for the most part not good. Passau proper stands between the right bank of the Danube and the left of the Inn, but it has several suburbs beyond: Innstadt, on the right bank of the Inn; Anger and Ilzstadt, on the left of the Danube,—the former above and the latter below the Ilz, which here joins that river from the north, opposite to the Inn. The Inn and the Danube are crossed here by wooden bridges; that over the latter resting on seven granite piers. The town and its suburbs are defended by citadels and fortifications, the strongest of which is the castle of Oberhause, on the left bank of the Ilz. Passau is in fact one of the most important strongholds on the Danube. Among the public buildings in the town, one of the most remarkable is the cathedral of St Stephen, an edifice originally built in the Gothic style, but which having been, with the exception of the choir, entirely destroyed by fire, was rebuilt in the Italian style. It contains many interesting monuments. In the Cathedral Square (*Domplatz*), which is the finest in Passau, stands a large bronze statue of King Maximilian Joseph. Besides the cathedral, there are in the town seven churches, some of which are fine buildings. The royal palace, formerly the residence of the bishops, and the post-office, in which the treaty of Passau was signed in 1552, are also worthy of notice. The town contains a public library, theatre, town-

hall, several schools and hospitals, an infirmary, and a lunatic asylum. The principal manufactures of the place are iron, copper, porcelain, pottery, tobacco, beer, leather, and paper. An active trade is carried on, both up and down the Danube. Passau is the capital of a bishopric which was formerly an independent state, but was secularized in 1803, and incorporated with Bavaria in 1809. The most important historical event that took place here was the treaty of 1552 between Maurice of Saxony and Ferdinand, King of the Romans, on behalf of Charles V., by which the religious freedom of the Protestants was secured. Pop. 12,000.

PASSERI, GIOVANNI BATTISTA, one of the greatest authorities on Italian art, was born at Rome about 1610. The circumstances of his career were peculiarly fitted to qualify him for writing on the fine arts. He practised composition both in prose and verse, and acquired the ease and skill of a professional *littérateur*. He cultivated, at Frescati, the friendship of Domenichino, and caught from the lips of that great artist a knowledge and appreciation of the great principles of art. He was also himself a painter of no mean standing, as his picture of the "Crucifixion between two Saints," in the church of San Giovanni della Malva at Rome still testifies. Accordingly, at his death in 1679, Passeri left behind him in manuscript a collection of lives of painters, sculptors, and architects, which has been considered one of the most authentic of art histories. In general its facts are accurate, its criticisms just, and its theories profound. It was first published by an anonymous editor, supposed to be Bottari, in 1772, and presented a biographical account of Italian art from 1641 to 1673 inclusive.

PASSERONI, GIAN CARLO, an Italian satirical poet, was born in the county of Nizza in 1713, and entered into holy orders. His career presents a rare instance of a good-natured contempt for the gifts of fortune. He was still young when he resigned the office of chaplain to the papal nuncio at Cologne, and retired to a humble cellar in Milan to enjoy solitude and practise austerity. A cock was his only companion, and a thread-bare suit and a few mean articles of furniture were his only riches. His door was closed against all donations, and all offers of place and position. He sat down at his humble table to write his *Il Cicerone*, a satirical poem which railed at fortune and society in easy and unaffected language, and in a strain of pleasant and decorous banter. The fame which this work gained for him did not affect his humility. A pension which the Cisalpine Republic bestowed on him did not alter his abstemious habits. He continued to cultivate frugality in his lonely cellar till he died in 1802, at the age of eighty-nine. Besides his *Il Cicerone*, which was published in 6 vols., Milan, 1768, Passeroni wrote *Translations of Several Greek Epigrams*, Milan, 1786–94; and *Æsopian Fables*, in 6 vols., Milan, 1786.

PASSIGNANO, the surname which Domenico Cresti, an eminent Italian painter, derived from his native place. He was born, according to some, in 1560, and according to others, about 1557. His studies were prosecuted at Venice under Naldini and Frederigo Zuccaro. He became a thorough-going admirer of the Venetian school, and learned to imitate Paul Veronese in the richness of his architecture and drapery. The brightest part of his professional career was spent at Rome. He painted the "Crucifixion of St Peter" for the church of St Peter's, and the "Entombing of Christ" for the Borghese palace. The closing years of his life were spent at Florence. He died there in 1638. The most distinguished of Passignano's pupils was Pietro Sorri of Siena.

PASSION-WEEK, the week immediately preceding Easter, and so called because in that week, according to some, happened our Saviour's passion and death. The Thursday of this week is called Maunday Thursday; the Friday, Good Friday; and the Saturday, the Great Sabbath.

PASSOVER (פֶּסַח; πάσχα, *a passing over, sparing, or protection*), a solemn Jewish festival having both a historical and a typical reference. As a commemorative institution, it was designed to preserve amongst the Hebrews a grateful sense of their redemption from Egyptian bondage, and of the protection granted to their first-born on the night when the destroying angel *passed over* the houses of the Hebrews, but slew all the first-born of the Egyptians (Exod. xii. 27); as a typical institute, its object was to shadow forth the great facts and consequences of the Christian Sacrifice (1 Cor. v. 7). The word *passover* has three general acceptations in Scripture:—1*st*, It denotes the yearly solemnity celebrated on the 14th day of Nisan or Abib, which was strictly the *Passover of the Lamb*, for on that day the Israelites were commanded to roast the paschal lamb, and eat it in their own houses; 2*d*, It signifies that yearly festivity, celebrated on the 15th of Nisan, which may be called the *Feast of the Passover* (Deut. xvi. 2; Num. xxviii. 16, 17); 3*d*, It denotes the whole solemnity, commencing on the 14th, and ending on the 21st day of Nisan (Luke xxii. 1), though in strictness of speech, the *Passover* and the *Feast of Unfermented Things* are distinct institutions. The Passover was to be kept on the eve of the 14th of the first month (Abib), in which, although unfermented things were enjoined to be eaten with the lamb, yet the feast of unleavened bread did not commence until the following morning. It continued seven days, of which the first and last only were sabbaths (Lev. xxiii. 5-8); the first probably in commemoration of the commencement of their march out of Egypt; the last of their passage through the Red Sea.

On the 10th of the month Abib, the master of a family separated a ram or a goat of a year old, without blemish (Exod. xii. 1–6; 1 Pet. i. 19), which was slain on the 14th day "between the two evenings," before the altar (Deut. xvi. 2, 5, 6). Originally the blood was sprinkled on the posts of the door (Exod. xii. 7), but afterwards the priests sprinkled the blood upon the bottom of the altar (comp. Deut. vi. 9; 1 Pet. i. 2; Heb. viii. 10; ix. 13, 14). The ram or kid was roasted in an oven, whole, with two spits forming a cross. It was next served up with a bitter salad, indicative of the bitterness of their bondage in Egypt, and eaten with unleavened or unfermented bread. Wine also to the quantity of four or five cups was drunk by each person. Considerable dispute has been raised as to whether the wine used on this occasion was fermented or unfermented,—was the ordinary wine, in short, or the pure juice of the grape. Those who hold it was unfermented appeal mainly to the expression "unfermented things," which is the true rendering of the word translated "unleavened bread." The rabbins would seem to have interpreted the command respecting ferment as extending to the *wine* as well as to the *bread* of the passover. The modern Jews, accordingly, generally use *raisin wine*, after the injunction of the rabbins. What of the flesh remained uneaten was to be consumed with fire, lest it should see corruption (comp. Exod. xii. 10; Ps. xvi. 10; Acts ii. 27). Not fewer than ten, nor more than twenty persons, were admitted to this sacred solemnity. At its first observance, the Hebrews ate the Passover with loins girt about, sandals on their feet, staves in their hands, and in haste, like travellers equipped and prepared for immediate departure (Exod. xii. 11); but subsequently the usual mode of reclining was adopted, in token of rest and security (John xiii. 23). The rabbins enumerate the following particulars as peculiar to its original observance, but which were afterwards modified:—1. The eating of it in their houses dispersed in Egypt; 2. The taking up of the paschal lamb from the tenth day; 3. The charge to

strike the blood on the door-posts; 4. The eating of it in haste (Bab. Talmud, *Pesachim*, c. 9; Maim. *Corban Pesach.*, c. 10, § 15). But the command not to break a bone of the offering was always observed (John xix. 36). The ceremonies practised at the eating of the paschal supper will be found fully detailed in the Mishna. (See Kitto's *Cyclopedia of Biblical Literature.*)

PASSPORT, a letter, license, or document of one sort or other, issued by competent authority, permitting the bearer to enter into and remain in a particular country, or portion thereof, for an indefinite or a specified time, and sometimes also for a specified purpose.

Every independent state has the right to exclude such individuals as it pleases from its territory; and it consequently has the right to require all strangers entering, or desiring to enter, its territories to bring with them properly authenticated documents showing what they are, and (if required) for what purpose they desire to visit the country. (See Marten, lib. iii., cap. 3; and a host of other authorities.) Passports have been introduced principally with the view of preventing persons hostile to the government or institutions of a country from crossing its frontier. And this obviously is a power which all governments would wish, were it in their power, to exercise and make effectual. But the widest experience has sufficiently proved that the facilities for travelling and for getting into extensive countries are now so great, that the regulations with respect to passports merely obstruct that free intercourse between the well-behaved and peaceable inhabitants of different nations that is so advantageous, without throwing any serious obstacle in the way of the transit of dangerous or suspicious characters. The latter have either little difficulty in obtaining passports under false pretences, or in making their way without them; and it is found that the countries in which the regulations as to passports are enforced with the greatest strictness are those in which suspicious characters are most common. On the whole, there can be little doubt that their abolition would be of great public advantage, and that it would not be productive, either in France or elsewhere, of any injurious consequences.

PASTO, a town of New Granada, in the province of Cauca, stands among the Andes, at an elevation of 8576 feet above the sea, 148 miles N.N.E. of Quito. In the vicinity is an active volcano. The town contains a fine church; and has some trade in wooden articles. Pop. 7000.

PASTORAL (Latin, *pastor*, a shepherd) is the name given to a species of poetry which is devoted to descriptions and delineations of country life, or to dramatic compositions in which the principal characters are shepherds or other rustics. (See ECLOGUE, BUCOLIC, and IDYLL.)

PASTORAL THEOLOGY is that department of theology which has to do with the practical duties of a clergyman as the teacher, counsellor, comforter, and guide of his spiritual flock.

PASTORAL LETTERS are those circulars addressed by a bishop (the *pastor* of his people) to his diocesans, for their religious instruction or guidance in matters of ecclesiastical discipline.

PATAGONIA, a large country of South America, occupying the southern extremity of that continent from the Rio Negro to the Strait of Magellan. It lies between S. Lat. 38. 50. and 53. 55., W. Long. 63. and 76., and is bounded on the N. by the Argentine Republic, E. by the Atlantic, S. by the Strait of Magellan, W. by the Pacific, and N.W. by Chili. Its length from N. to S. is 970 miles, its breadth varies from 200 to 420, and its area is about 300,000 square miles. The country is divided into two regions differing widely from each other in their general character. The one of these lies along the west coast, and is entirely mountainous; while the other, to the east, is in general low and flat. In the western region, the mountains all belong to the chain of the Andes, which is here much lower than in the more northerly parts of South America, for the average height of the range in Patagonia does not exceed 3000 feet; but even here there are some mountains upwards of 7000 feet above the sea. Southwards from the Gulf of Ancud, where the Chilian and Patagonian territories meet, the country along the shore of the Pacific presents an aspect quite different from that which is met with farther north. Instead of having a narrow strip of low land, with an almost unbroken coast extending between the mountains and the Pacific, as is generally the case on this coast, the Patagonian Andes rise abruptly out of the sea, which, frequently flowing into the deep defiles of the mountains, extends long and winding arms far into the land. Numerous high and rocky islands, rising abruptly out of the sea, line the coast. The chief of these are,—Chiloe, the Chonos Archipelago, Wellington Island, the Archipelago of Madre de Dios, Hanover Island, and Queen Adelaide's Archipelago. There is also a large peninsula, called Tres Montes, lying between the Chonos Archipelago and Wellington Island, joined to the mainland by a narrow isthmus. Near the southern extremity of Patagonia two remarkable inlets break the continuity of the Andes chain. The first of these divides itself into two branches,—Last Hope Inlet, extending to the N., and Ancon Sin Salida, or Obstruction Sound, to the S.; while the second, which is much larger, spreads itself out in two sheets of water—Otway Water and Skyring Water—connected by a narrow strait. Farther to the S., not only the mountain chain, but the entire mass of the land is divided by the Strait of Magellan, extending from the Pacific to the Atlantic, and separating Tierra del Fuego and the adjacent islands from Patagonia. All the mountains of Western Patagonia, as well as those on the islands, are thickly wooded on their western declivities, but entirely bare on the side that is exposed to the ocean. The whole of the region is subject to incessant winds and rains, the breezes being generally from the W., and bringing from the Pacific an immense quantity of moisture, which is condensed on the mountains, and deluges the country with almost incessant showers. The ground is thus kept constantly wet; and there are few days in the year when rain does not fall in summer, or snow and sleet in winter. The largest river in Western Patagonia is the San Tadio, a small stream which falls into the Pacific S. of the peninsula of Tres Montes. It is formed by two mountain torrents, and is navigable for about 11 miles. On the mainland opposite the island of Chiloe there are two volcanoes, the farthest S. of any that are known to have been active in modern times. These are Minchinmadiva, 8010 feet, and Corcovado, 7500 feet above the sea. The eastern part of Patagonia is in its surface and climate the very reverse in many respects of the western. The land is low and flat, rising gradually in terraces from the Atlantic to the Andes. The uniformity of the surface is, however, broken by the high lands of Espinosa, which occupy a large promontory between S. Lat. 47. and 48., and rise to the height of 4000 feet above the sea. In the southern portion of the country the soil consists of tertiary strata, covered over with shingle, and destitute of all vegetation, except here and there scattered tufts of grass and low bushes. Although numerous salt pools occur in this region, there is a great scarcity of fresh water. North of 45. S. Lat., the country is more undulating, and not so entirely destitute of vegetation as the southern portion; for in some places the valleys and low hills are covered with grass and stunted trees, and there are even parts where good pasturage and timber may be obtained. Eastern Patagonia is traversed by several rivers, which are much larger than those that water the western region. The Rio Negro, which forms the northern

Patagonia. boundary of Patagonia, rises in the Andes, flows first N.E., then E., and finally S.E., falling into the Atlantic. Its whole length is about 700 miles; and at a long distance from its mouth it has a breadth of 500 yards. Of the other rivers little is known except their mouths; the Chupat, the Camerones, the Desire River, the Santa Cruz, and the Gallegos, are the most important,—all falling into the Atlantic. The Santa Cruz is a river of considerable size, and is believed to flow through several lakes, one of which, Lake Capar, is 30 miles long and 10 or 12 broad. This river flows for a great part of its course in a deep valley, through an elevated plain which rises in some parts 1800, and in others between 2000 and 3000 feet above the sea. Along the banks there are in some places deep and extensive layers of lava. The eastern coast of Patagonia, from the entrance of Magellan's Strait as far northwards as 49. S. Lat., consists of cliffs of marly clay rising 200 or 300 feet perpendicularly from the sea, and somewhat resembling, when seen from a distance, the coast of Kent. North of this, as far as 45. S. Lat., the cliffs are somewhat higher, and their prevailing structure is porphyritic. Beyond this point the coast presents a different aspect, consisting of a shingly beach skirted by a reef of rocks. The largest gulfs of the eastern coast are those of San Matias, S. of the Rio Negro; and St George, N. of Cape Blanco. There are also several harbours along this coast, such as Port San Antonio, in 41. S. Lat.; Nuevo Golfo, in 43.; Port Desire, in 47. 5.; Port San Julian, in 49. 12.; Santa Cruz, in 50. 7.; and Gallegos, in 51. 38. The climate of Eastern Patagonia is as remarkable for dryness as that of the western region is for its constant showers. Captain Fitzroy, who explored the Patagonian coasts between the years 1826 and 1836, thus speaks of the climate of this country:—"One naturally asks why Eastern Patagonia should be condemned to perpetual sterility, while the western side of the same country, in the same parallel of latitude, is injured by too much rain? The prevailing westerly winds and the Andes are the causes. The winds bring much moisture from the Pacific, but they leave it all, condensed, on the west side of the mountains. After passing the cordillera, those same winds are very dry. Easterly winds are very rare upon the east coast; they are the only ones which carry rain to the almost deserts of Patagonia. Westward of the Andes, an east wind is dry and free from clouds. All this country is exposed to severe cold weather in winter, and to excessive heat in summer. Great and sudden changes of temperature take place, when, after very hot weather, cold winds rush northwards with the fury of a hurricane." The temperature of the country S. of the 45th parallel of latitude is in general extremely cold, although during the short summer great heat is experienced. The vegetable products of Patagonia are very scanty, the only portion where there is a luxuriant vegetation being the country near the Rio Negro, in which the same plants are found as in the adjacent parts of the Argentine Republic. Among the forests of the west several species of beech and many large and beautiful ferns occur. Animals are found in greater abundance than vegetables in most parts of Patagonia. Herds of guanacoes, amounting to several hundreds in number, roam about the country; and the puma, the wolf, the fox, the opossum, the cavia, the armadillo, the otter, and the seal, are also met with. There are an immense number of animals of the class Rodentia,—more, perhaps, than in any other part of the world. The horse is found in all parts of the country, being the invariable companion of the natives of Eastern Patagonia. The condor and the cassowary are the principal terrestrial birds; but the sea-fowl are very numerous, including several species of swans, ducks, and geese. Fish and other sea-animals are plentiful along the coasts.

The aboriginal natives of Patagonia are a tall and extremely robust race of men. Their bodies are bulky, and their head and features large, but their hands and feet are small. Their limbs are neither so muscular nor so large-boned as their height and apparent bulk would lead one to suppose; they are rounder and smoother than those of white men. Their colour is a rich reddish brown, rather darker than the hue of copper. The only attractive feature about their persons is their teeth, which are sound and white. Their cheek-bones are prominent, and so is their brow, which is broad but low. Their heads are furnished with a profusion of rough, lank, and coarse black hair, which is tied above the temples by a fillet of plaited or twisted sinews; and they wear no other covering upon this part of their body. The size of the Patagonians has been represented by some writers as quite gigantic; and, although the earlier voyagers have given somewhat exaggerated accounts of them, which have been improved by some subsequent authors, it seems to be the universal testimony of those who have visited the country in modern times, that they do considerably exceed the average stature of Europeans. Captain Byron, in the middle of last century, saw a number of men above 8 feet, and some as much as 9 feet in height. Captain Fitzroy thus speaks of the natives that he saw:—"Among two hundred or three hundred natives of Patagonia scarcely half a dozen men are seen whose height is under 5 feet 9 or 10 inches; the women are proportionably tall. I have nowhere seen an assemblage of men and women whose *average* height and *apparent* bulk equalled that of the Patagonians. Tall and athletic as are many of the South Sea islanders, there are also many among their number who are slight and of lower stature. The Patagonians seem to be high-shouldered, owing perhaps to their habit of folding their arms across the chest, in their mantles, and thus increasing their apparent height and bulk, because the mantles hang loosely, and almost touch the ground. Until actually measured, it is difficult to believe that they are not much taller than is the case."

Mr Bourne, an American seaman, who was for some time a captive in Patagonia in 1849–50, says that their average height is 6½ feet, while some nearly reach 7 feet. These accounts are so precise and satisfactory that the question as to the actual size of the Patagonians may be regarded as completely set at rest. Is it more improbable that there should be races of men *above* the European standard, than it is that there should be races whose height is *below* it? Yet we know beyond a doubt that the Esquimaux are so.

With the exception of the head, little hair grows upon their bodies; and from the face it is carefully removed by shells or pincers. They do not disfigure their naturally coarse features by piercing either nose or lip, but they bedaub their body with white, black, or red paint, forming grotesque figures, such as circles around their eyes or great marks across their faces. This ornamental body-painting is practised by all the different races of Patagonians from Cape Horn to Buenos Ayres. On their feet and legs they wear boots made of the skins of horses' hind legs. Spurs made of wood, but of iron if they can get it, balls (*bolas*), or stones, attached to a long leather thong, for the purpose of catching the guanaco or the ostrich by throwing the balls so as to wind round their legs, whilst a long tapering lance, and a knife, if it can be procured, complete their equipment. "Mounted upon horses of a middle size," says Captain Fitzroy, "under fifteen hands high, and rather well bred, the Patagonians seem to be carried no better than dragoons who ride eighteen stone upon horses able to carry ten; yet they go at full speed in chase of ostriches or guanacoes. When hunting or making long journeys they often change horses. The women are dressed and booted like the men, with the addition of a half

petticoat. They clean their hair, and plait it into two tails. Ornaments of brass, beads, bits of coloured glass, or such trifles, are prized by them. The huts of these wanderers are somewhat like gipsy tents. Poles are stuck in the ground, to which others are fixed. Over them are thrown the skins of animals, an irregular tilt-like hut being thus formed." It is to be observed that the inhabitants of Tierra del Fuego, and of the islands to the S. and S.W., wear little or no clothing. The Patagonians appear to possess nothing like towns, but lead a wandering and unsettled life, somewhat resembling that of the Tartars. The different parts of the country are inhabited by several distinct nations, the chief of which are the following:—The Moluche, or Warrior Indians, who inhabit the Andes and neighbouring regions immediately S. of the Rio Negro; the Puelche, or Eastern People, who wander about the N.E. of Patagonia; the Chulian Indians, who occupy the mountainous regions S. of 42. S. Lat.; the Te-huel-het, or Southern People, who inhabit the south-eastern extremity of the country; and the Fuegians, who people not only the island of Tierra del Fuego, but the western coast of the mainland, as far N. as the peninsula of Tres Montes. The last of these differs from the others in being of much lower stature. The various tribes into which they are divided are generally under the command of chiefs; and they subsist chiefly on the flesh of mares, guanacoes, emus, &c. Very few traces of any religious ceremonies have been observed among them. We are informed by Falconer, the Jesuit missionary, that after the dead have been interred twelve months, the graves are visited by the tribe for the purpose of collecting the bones, and conveying them to their family sepulchres, where they are set up, and adorned with all the beads and ornaments which the friends and family of the deceased are able to collect for the occasion. The ceremony is performed by certain women of the tribe, whose peculiar office it is to attend to these rites. In corroboration of the Jesuit's testimony, Captain King informs us, that near Port Desire he had seen the graves of the Indians upon the summits of hills, but without the bodies, which he supposes to have in all probability been removed by the Indians.

It seems highly probable that Magalhaens was the original discoverer of the southern coast of Patagonia and the northern coast of Tierra del Fuego, as well as of the strait which bears his name. Sir Francis Drake passed the strait in the year 1578; and being driven by storms to the S., discovered the western and south-western coast of Tierra del Fuego, and also Cape Horn; although the honour of the discovery of the latter has generally been ascribed to Jacob Le Maire, a Dutchman in the service of the states of Holland. In the year 1616 this navigator was the first who doubled that terminus of South America, and called it Cape Horn, after a village in Holland. Proceeding in a north-easterly direction, he crossed the strait which bears his name, and discovered Staten Island, which he so designated after the states of Holland. It is supposed that Davies, one of the companions of Cavendish in his voyage to the South Seas in 1592, was the first person who saw the Falkland Islands; but they were not, properly speaking, discovered till the year 1594, when Sir Richard Hawkins examined them, and called them in honour of his queen and himself, Hawkins' Maiden Land. The name, however, was subsequently changed to Falkland Islands by Strong, another English navigator. During the early part of the eighteenth century they were re-discovered by some French navigators; and hence the origin of the French name, Malouine Islands. To Captain Cook we are indebted for the first accurate account of the south-eastern coast of Tierra del Fuego, which he explored in 1774; and so little was known concerning it before this period that, when actually in sight of Cape Horn, he was unable to decide whether it was a detached island or a part of Tierra del Fuego. Amongst the other distinguished names connected with the discovery or investigation of this part of the South American continent, are those of Sarmiento (whose account of a voyage down the western coast, and through the Strait of Magalhaens, has never been surpassed), Sir John Narborough, Cordova, Byron, Willis, Carteret, Bougainville, Weddel, King, Stokes, and Fitzroy. It only remains to be noticed that, although repeated attempts had been made to form permanent settlements in Patagonia, or upon the neighbouring islands, particularly by the Spaniards, until recently none of these has been successful. In 1843, however, the government of Chili founded a settlement at Port Famine, on the Strait of Magellan, which was in 1850 transferred to Sandy Point, some distance to the N. This colony contained in 1853 about 20 houses, with a chapel and sacristy. The population was 150; and they had 10 horses, 18 goats, and a number of swine. Another settlement on the strait has recently been projected; and in 1854 an exploring expedition was sent thither with a view to that undertaking. The western part of Patagonia is claimed by Chili, and the eastern by the Argentine Republic. With regard to population, it must be quite obvious that no accurate idea can be formed. It has, however, been estimated at 120,000. By far the greater part of the country—that which stretches along the eastern side of the Andes, from their base to the Atlantic Ocean—is almost entirely unknown, with the exception of a very few places upon the coast. It is quite possible, therefore, that the inhabitants may be far more numerous in this region than is supposed; but the general sterility of the country holds out little prospect of any great commercial advantages to be gained by intercourse with them, except in the precious metals, which are doubtless to be found in the Patagonian Andes.

PATAK, Saros, a market-town of Hungary, county of Zemplin, on the right bank of the Bodrog, here crossed by a bridge, 14 miles S.W. of Zemplin. It contains a once famous but now ruined castle, a celebrated Protestant college, a Roman Catholic upper school, &c. Cloth is manufactured here; and wine is produced in the vicinity. Pop. 5480.

PATANI, a small kingdom on the eastern coast of the Malay Peninsula, subject to Siam. It is the most fertile portion of Malacca; rice and salt are obtained in large quantities; and these articles, as well as tin, are exported. The chief town, Patani, stands on the coast, N. Lat. 7., E. Long. 105. 35.; and was formerly much resorted to by vessels trading between India and China, though at present it is rarely visited. There is, however, some communication kept up between this place and Singapore. Patani is also the name of a cape on this coast, at the entrance of the Gulf of Siam.

PATAVINITY (*patavinitas*), properly the mode of speaking peculiar to the people of Patavium, is a term employed by literary critics, to denote generally any provincial idiom. The word takes its origin from the alleged provincialisms to be found in the writings of Livy, who was a native of Patavium, a provincial town belonging to the Roman empire. According to Quintilian (i. 5, § 56; viii. 1, § 3), Pallio censured the historian for this alleged defect, but it does not appear that any critic has ever pointed out precisely in what the patavinity of Livy really consists. It was perhaps of so subtle and delicate a nature that we are no longer in a position to detect it. Niebuhr simplifies the matter by altogether disbelieving Quintilian's story.

PATAVIUM. See Padua.

PATENTS: Letters Patent *for Inventions.* These are documents bearing the great seal of the United Kingdom, by which inventors obtain a monopoly in their inventions for a certain number of years; which monopoly is similar in principle to that conceded to authors and artists

under the name of copyright. There are persons who argue that no such privilege should be permitted; there are others who think that the most trifling exertions of the inventive faculties should be protected. The right course lies between these extremes. All civilized nations have considered it desirable to give inventors an exclusive right to their inventions for a limited period, not only as a matter of justice to individuals, but as a piece of sound policy tending to the advantage of the whole community. The monopoly is granted in the expectation that the inventor will derive some profit from it; and the hope of profit is known to be a great stimulus to invention. When an author writes a book, or an artist designs a picture, the law allows a right of property to those persons in their productions, and accompanies the recognition of this right with the power to repress infringements. If this were not so, very few persons would employ their time in writing books or creating works of art; and hardly any one will be bold enough to assert that the extinction of the race of authors and artists is to be desired. The same principle applies to inventors, who ought to have the works of their brain protected from piracy fully as much as the other classes of mental producers. By holding out to them the prospect of gain, they are induced, at a present loss of time and money, to attempt to discover improvements in the useful arts, in machinery, in manufacturing processes, &c.; and thus the interests of the community are advanced more rapidly than if such exertions had not been brought into play. Just as the rule of rewarding inventors is in theory, the practical application of it is attended with difficulty. To grant a very long term of exclusive possession would be detrimental to the public, since it would tend to stop the progress of improvement. A limited property must therefore be allowed; large enough to give the inventor an opportunity of reaping a fair reward, but not barring the way for an unreasonahle period. And when this compromise has been decided on, it will be seen how difficult it may be to determine beforehand what is the real merit of an invention, and apportion the time to that merit. Hence it has been found necessary to allot one fixed period for all kinds of inventions falling within the purview of the patent laws. This regulation appears to be open to the complaint, that the most worthless and the most meritorious inventions are placed on the same footing. But it may be replied, that in the result this is of little consequence, since meritorious inventions alone obtain the patronage of the public, those which are destitute of value being neglected. Besides, if the complaint were well founded, there is here no sound argument against the policy of privileges of this nature, seeing that it is impossible to weigh beforehand one invention against another in the scale of merit, or to obtain a true standard of comparison.

Leaving the discussion of general considerations, we will now give an outline of the law affecting patent privileges in the United Kingdom. In the old times, the reigning prince considered himself entitled, as part of his prerogative, to grant privileges, in the nature of monopolies, to any one who had acquired his favour. These grants became so numerous that they were oppressive and unjust to various classes of the commonwealth; and hence, in the reign of James I., a statute was wrung from that king which declared all monopolies that were grievous and inconvenient to the subjects of the realm to be void. There was, however, a special exception from this enactment of all letters patent and grants of privilege of the "sole working or making of any manner of new manufactures which others at the time of making such letters patent and grants should not use, so they be not contrary to law, nor mischievous to the state." Upon these words hangs the whole law of letters patent for inventions. Various statutes were afterwards passed (which it would be well to consolidate into one act), and the principal of these is the Patent Law Amendment Act of 1852. These statutes, however, do not materially alter the law; it is chiefly the practice of obtaining letters patent, and their form, that are affected. The positive law has to be gathered from the numerous decisions of the courts, for patent law is for the most part "judge-made law." Of that law, as it now stands, we proceed to give an outline.

The inventions for which patents are obtained are chiefly either vendible articles formed by chemical or mechanical operations, such as cloth, alloys, vulcanized india-rubber, &c.; or machinery and apparatus, or processes. It may be remarked here, that a scientific principle cannot form the subject of a valid patent unless its application to a practical and useful end and object is shown. An abstract notion, a philosophical idea, may be extremely valuable in the realm of science, but before it is allowed to form a sound basis for a patent, the world must be shown how to apply it so as to gain therefrom some immediate material advantage. With regard to processes, the language of the statute of James has been strained to bring them within the words "any manner of new manufactures," and judges on the bench have admitted that the exposition of the act has gone much beyond the letter. However, it is undoubted law that a process is patentable; and patents are accordingly obtained for processes every day.

The principal classes of patentable inventions seem to be these:—

1. New contrivances applied to new ends.
2. New contrivances applied to old ends.
3. New combinations of old parts, whether relating to material objects or processes.
4. New methods of applying a well-known object.

We have not space to enlarge upon these rough divisions, and will only remark, with regard to a patent for the new application of a well-known object, that there must be some display of ingenuity in making the application, otherwise the patent will be invalid on the ground that the subject-matter is destitute of novelty. For example, a machine already in use as an excavator on land cannot be separately patented as an excavator under water; nor can a machine employed in the finishing of cotton goods be afterwards patented as applied to the finishing of woollen fabrics. A small amount of invention is indeed sufficient to support a patent where the utility to be derived from the result is great. A small step in advance, a slight deviation from known processes, may have been apparently brought about by the exercise of little ingenuity; but if the improvement be manifest, either as saving time or labour, a patent in respect of it will stand. The mere omission of a step from some commonly practised process has been held sufficient to support a patent for a new method of manufacture; and how often do we see what appears to be a very trifling degree of novelty, attended with very advantageous consequences, sometimes resulting in the entire revolution of a manufacture, or in a lowering of price appreciable in every pound of an article extensively used by the public.

Whatever be the nature of the invention, it must possess the incidents of utility and novelty, else any patent obtained in respect of it will be invalid. The degree of utility need not, however, be great; it is sufficient if a jury can find some utility in it. As to novelty, this is the rock upon which most patents split; for if it can be shown that other persons have used the invention before the date of the patent, it will fall to the ground, although the patentee was an independent inventor deriving his ideas from no one else. The difficulty of steering clear of this rock will be apparent at once. Suppose A. in London patents an invention the result of his own ingenuity and patient study, and it afterwards appears that B., in some distant part of the kingdom, had been previously openly using the same thing in his workshop, A.'s patent is good for nothing. Thus, in one of the cases which

arose out of Heath's carburet of manganese patent, a patent celebrated in the law courts, it appeared that three firms had used a process in the manufacture of steel which was substantially the same as that forming the subject of the patent. They had used the process openly in the way of their trade previous to the date of the patent, although it had not become generally known. This prior use of the invention was held to deprive the patent of validity. It is therefore a very frequent subject of inquiry, whether an invention has been previously used to such an extent as to have been publicly used in the sense attached by the courts to this phrase; the more especially as, if the prior use of the invention by some other person has not been public and general, an act of Parliament (5 and 6 Will. IV., cap. 83) has given the patentee a remedy against the strict rule of law by means of a petition to the Privy Council. The inventor himself is not allowed to use his invention either in public or secretly, with a view to profit, before the date of the patent. Thus, if he manufactures an article by some new process, keeping the process an entire secret, but selling the produce, he cannot afterwards obtain a patent in respect of it. If he were allowed to do this, he might in many cases easily obtain a monopoly in his invention for a much longer period than that allowed by law. The rule, that an inventor's use of the invention invalidates a subsequent patent, does not, however, apply to cases where the use was only by way of experiment with a view to improve or test the invention. And it has been repeatedly decided that the previous experiments of other persons, if incomplete, or abandoned before the realization of the discovery, will not have the effect of vitiating a patent. Nor will such an effect be produced by the previous discovery of the subject-matter of a patent, if the discoverer keeps the secret to himself, the law holding that he is the "true and first inventor" referred to in the statute of James, who first obtains a patent.

When an invention is the joint production of more persons than one, they must all apply for and obtain a joint patent, for a patent is rendered invalid on showing that a material part of the invention was due to some one not named therein. The mere suggestion of a workman employed by an inventor to carry out his ideas will not, however, require that he should be joined, provided that the former adds nothing substantial to the invention, but merely works out in detail the principle discovered by his employer. In certain cases in which patents taken out by the celebrated Sir Richard Arkwright came to be inquired into, it was proved that the inventions were really made by persons in Arkwright's employment. Their value being perceived by him, he adopted them, and obtained the patents in question, but under these circumstances they were adjudged invalid.

If it can be shown that the invention in respect of which a patent has been obtained was previously described in a printed book in circulation in Great Britain, whether such book be in the English or a foreign language, the patent is also invalid; because a man has no right to obtain a monopoly in that which is already a part of the stock of public information; and it is not necessary to prove that the patentee was acquainted with the book, and derived his ideas from that source.

But persons are allowed to obtain patents for inventions imported from abroad, if such inventions are new within the realm, and if they acknowledge, on the face of their petitions, that the inventions are imported, not original. Such patents are now common. If the invention has been patented abroad, the law directs that the British patent shall expire at the same time as the foreign patent.

The attributes of novelty and utility being possessed in due degree by an invention, the chief remaining difficulty with which a patent has to contend resides in the specification, the instrument by which the inventor describes the nature of the invention, and the means by which it may be carried into effect. An inventor is bound, in return for the monopoly conceded to him, to instruct the public how to work the invention when the monopoly shall have expired, and to inform them in the meantime what it is they are shut out from using. The patentee may either file this instrument along with his petition for a patent, or he may reserve it until the end of six months from the date of the patent. In either case, he must make a full disclosure of his secret; he must not keep anything back either wilfully or accidentally; he must render everything plain and clear, showing no attempt to mislead, and leaving nothing ambiguous; he must distinguish what is old from what is new, and take care that he claims no more than he is entitled to; in short, the invention must be accurately and intelligibly described, properly limited, and communicated to the public in such a way that they may have a complete knowledge of that in which they are granting to him a temporary monopoly. Very many patents have been invalidated by inattention to these rules in framing the specification, — the most common fault being, that it claims too much; in other words, it claims something that is already public property, or another man's patented invention. And here we are brought back again to the question of novelty.

If a patentee discovers that his specification claims more than he is entitled to, he may put the matter right by filing a disclaimer, and excising the superfluous parts; but he will not be allowed to extend his claims in any degree. He may cut out anything, but he can insert nothing.

The term for which a patent is originally granted is fourteen years, but the Crown has power, under an act of Parliament (5 and 6 Will. IV., c. 83), and on the report of the Judicial Committee of the Privy Council, before which the proceedings to this end take place, to extend the time of a patent from its expiration for any additional time not longer than fourteen years. But an extension will only be granted on the patentee showing that he has not been adequately rewarded; and what is adequate reward depends on the special circumstances of each case.

Patent privileges, like most other rights, can be made the subject of sale. Partial interests can also be carved out of them by means of licenses, instruments which empower other persons to exercise the invention, either universally and for the full time of the patent (when they are tantamount to an assignment of the patentee's entire rights), or for a limited time, and within a limited district. By an exclusive license is meant one that restrains the patentee from granting other licenses to any one else. By means of a license a patentee may derive benefit from his patent without entering into trade, and without running the risks of a partnership.

A patentee's remedy for an infringement of his rights is by civil suit, there being no criminal proceeding in such a case. In prosecuting such suit, he subjects those rights to a searching examination, for the alleged infringer is at liberty to show that the invention is not new, that the patentee is not the true and first inventor, &c., as well as to prove that the alleged infringement is not really an infringement. But it may here be remarked, that a patentee is not bound down (unless he chooses so to be) to the precise mode of carrying the invention into effect described in the specification. If the principle is new, it is not to be expected that he can describe every mode of working it; he will sufficiently secure the principle by giving some illustrations of it; and no person will be permitted to adopt some mode of carrying the same principle into effect, on the ground that such mode has not been described by the patentee. On the other hand, when the principle is not new, a patentee can only secure the particular method which he

has invented, and other persons may safely use other methods of effecting the same object. Instances of this occur every day; and it is well known that scores of patents have been taken out for screw-propellers, steam-hammers, water-meters, &c., each of which is limited to the particular construction described, and cannot be extended farther. Again, where the invention patented consists of a combination of parts, some old and some new, the whole constituting a new machine or a new process, it is not open to the world to copy the new part and reject the rest. A man is not suffered to allege that the patent is for a combination, and that the combination not having been used, there has been no infringement.

The Crown has power to repeal any letters patent on good grounds being shown by means of a writ of *scire facias;* and this is issuable at the request of any subject. Want of novelty in the invention, the fact of the patentee not being the inventor, and the insufficiency of the specification, form good grounds for repealing a patent.

Patents are not now extended to the colonies, and such of our colonies as possess a legislature are gradually acquiring patent laws for themselves.

The patent business of the United Kingdom is carried on under the direction of commissioners appointed by the act of 1852, the chief of whom is the lord chancellor; and the whole of it is transacted at one office in London, instead of at many offices, as formerly. Previous to that act, a separate patent was issued for each of the three kingdoms, but now one patent is valid throughout the realm. The proceedings taken with a view to obtain a patent commence with the presentation of a petition, accompanied by a sketch of the invention and a declaration of its originality. Various steps are interposed before the patent is issued, in order to afford those who have grounds for opposing the grant an opportunity of doing so. Most patents are obtained through persons styled *patent agents*, who devote themselves to this branch of business. The act just referred to introduced various useful reforms in the proceedings for obtaining patents, but greater simplicity and a lessening of the expense are still desirable.

(For further information on the subject of this article, the reader is referred to Johnson's *Patentee's Manual*, second edition, 1858, as comprising an exposition of the law and practice within a moderate compass.) (J. Y. J.)

PATERA, a broad flat dish, or libation-saucer, among the Romans, deriving its name, according to Macrobius (*Sat.* v. 21), from its *open*, shallow form ("planum ac patens est"). The ordinary pateræ were made of common red earthenware, slightly ornamented; but the more valuable vessels of this class were composed for the most part of bronze, and every family of easy circumstances possessed one of silver. The original use of the patera seems to have been domestic, which gave origin, in all likelihood, to its employment at sacrifices. Numerous specimens of pateræ are to be seen in almost all collections of ancient fictile vases, and especially in the British Museum.

PATERCULUS, Caius Velleius, a Roman historian, was the son of a præfect of cavalry, and is conjectured to have been born in 19 B.C. He was descended from a Campanian family which had been distinguished during several generations for its devoted attachment to the Romans. One of his ancestors, Decius Magius, was the leader of the Roman party in Capua when the majority of the citizens were revolting to Hannibal. Another of his ancestors, Minatius Magius, fought zealously and bravely on the side of Rome in the Social War. His grandfather also, a retired captain of the artificers, was so chagrined when the infirmities of age would not permit him to follow his general, Claudius Nero, into banishment, that he run himself through with his own sword. From these old heroes Paterculus inherited a warlike zeal and energy. Succeeding his father in 4 A.D. as a præfect of cavalry in the army of Tiberius Cæsar in Germany, he soon gained preferment and honour. He obtained the quæstorship in 7 A.D., a share in the triumphal honours of his general in 12 A.D., and the prætorship in 14 A.D. His services and abilities seem also to have secured for him the friendship of the Emperor Tiberius, and of the emperor's rising favourite, Sejanus. It was, however, in the character of a historian that Paterculus won his brightest laurels. In 30 A.D. he sat down to write a historical compendium which should embrace not only the annals of his own country down to his own time, but also those of the rest of the civilized world. The cursory nature of such a work would not permit him to dwell long upon any particular scene, and whirled him along, as he said himself, "with the rapidity of a wheel or torrent." Yet, by omitting all incidents that were not absolutely essential, and by describing at length those events that formed the characteristics of the several ages, he succeeded in making his narrative at once comprehensive and interesting. The shortness of the time allotted for the task often hurried him into confused and slovenly sentences. Yet he narrated facts with great point and vigour, and made reflections that were strikingly original and appropriate. The work was finished the same year in which it had been begun; and was dedicated to M. Vinicius, the ruling consul. When and how Paterculus died have not been ascertained. It has been conjectured that he was involved in the ruin of Sejanus in 31 A.D., along with that minion's other friends. The work of Paterculus has come down to modern times under the title of a *Roman History*, and with some of its parts wanting. Beatus Rhenanus discovered the manuscript in the monastery of Murbach in Alsace, and printed it at Basle in 1520. The most valuable edition is that of Ruhnken, Leyden, 1779, reprinted by Frotscher, Leipsic, 1830–39. The edition of Orelli, Leipsic, 1835, contains some textual improvements. An English translation of Paterculus forms, in conjunction with translations of Sallust and Florus, a volume of Bohn's "Classical Library."

PATERNO, a town of Sicily, province of Catania, stands at the foot of Mount Ætna, 10 miles N.W. of Catania. It is a very ancient place; and contains numerous convents and churches. The surrounding country is fertile, producing corn, oil, wine, flax, hemp, and timber; in which articles an active trade is carried on. In the vicinity of the town are mineral springs and a salt mine. Paterno gives the title of Prince to one of the principal families of Sicily. Numerous vestiges of antiquity have been discovered here; among others, the remains of baths, a tomb, an aqueduct, and a ruined bridge. The town is supposed to occupy the site of the ancient Hybla Major. Pop. 10,700.

PATERSON, a town of the United States of North America, in the state of New Jersey, stands on the right bank of the Passaic River, 13 miles N. of Newark, and 17 N.W. of New York. The streets are straight and well paved, and the houses substantially built. There are about eighteen churches, belonging to various sects, and some of them are edifices of much elegance. There are also a court-house, jail, two banks, several schools, a philosophical society with a library, and a mechanics' institution. The manufactories of the place are extensive. There are about twenty cotton factories, several dyeing and printing establishments, two large manufactories of locomotives, besides paper-mills, fulling-mills, foundries, &c. Paterson is thus one of the principal manufacturing towns in the States; and in New Jersey it is second only to Newark. Immediately above the town the Passaic falls over a precipice 50 feet high. This forms, during the time of flood, a magnificent spectacle. A great part of the water is carried off by a canal into a basin, from which, by different channels, it is conveyed to the various mills of the town. Paterson is connected by railway with New York, and by canal with

the Atlantic. On the opposite side of the river, which is crossed by two bridges, stands the village of Manchester. Paterson was originally founded in 1791 by a company for the manufacture of cotton; and although it had to be abandoned soon afterwards, the original design was subsequently carried out. Pop. (1850) 11,338; (1853) about 13,000.

PATERSON, William, founder of the Bank of England, was born, according to tradition, at Skipmyre in Tinwald, Dumfriesshire, and, as his will testifies, in the spring of 1665. Little is definitely known respecting the early part of his career. He is said to have been originally destined for the Scottish Church, and received accordingly a suitable elementary education. While yet a lad, however, he was compelled, it is said, to flee to England for safety from the persecutions then raging in his native country against the outlawed Presbyterians, with whom he at that early age seems to have associated. He found refuge in the house of a maternal relative in Bristol, who, dying soon after, left young Paterson some trifling property. Having succeeded as a pedlar, as some would have it, he took up his residence in London in the capacity of a merchant. Traces of him are to be found about this time in the West Indies, some say in the character of a bucaneer, but more probably in the capacity of a merchant. Whether or not this occurred previous to his taking up his residence in the metropolis, does not definitely appear. At all events, during his residence abroad he acquired extensive information respecting Spanish America, which he found frequent occasion to turn to account, and especially in connection with the Darien expedition. Much of this information he could only have obtained through the bucaneers; yet there is sufficient reason to believe that he was in no way associated with the exploits of these naval marauders. On his return to England, Paterson seems to have projected schemes of trade more bold and original than any yet known among the trading companies of Britain. He is believed to have contributed largely to the pages of a pamphlet published ostensibly by his friend Sir Dalby Thomas in 1690, and entitled *An Historical Account of the Rise and Growth of the West India Colonies, and of the great advantage they are to England in respect of Trade.* The great ability and strict integrity of Paterson had by this time gained for him an eminent standing in society; and his monetary schemes seem to have been listened to by the wisest heads in the country. Among his attached friends he counted Fletcher of Saltoun and Baillie of Jerviswood, countrymen of his own; and he was in close alliance with such eminent men of business as Godfrey and Sir Theodore Jansen. His financial proposals in connection with the founding of the Bank of England met with strenuous opposition, however, from Lowndes, secretary to the Treasury. A tract entitled *A Brief Account of the Intended Bank of England*, London, 1694 (the year of its foundation), is supposed to have come from Paterson's pen. (For an account of the establishment of this bank, see Money, § iii.) Despite his eminent services in projecting the bank, a difference of opinion seems to have soon arisen between him and the directors, which induced him to resign his connection with it. It seems certain that, so far from participating in the foundation of the Bank of Scotland in 1695, he was decidedly opposed to it. The project of "a free commonwealth in Darien" had long occupied the thoughts of this enterprising trader. Even so far back as 1687 we find him advocating the scheme in the coffee-houses of Amsterdam. For at least ten years he had been pressing his plan upon the English minister and upon foreign states; when about 1695, at the request of certain of his countrymen, he visited Scotland, and in all probability drew up the Scottish act of that year constituting the Darien company. Accordingly "twelve hundred men sailed in five stout ships" on that ill-fated expedition from the harbour of Leith, on the 26th July 1698; but Paterson had no share in the management of it, and embarked with the fleet in the capacity of a private adventurer. What with the gross mismanagement of the council of seven, the opposition of the English government, and other unfavourable circumstances, this unfortunate colony came to utter ruin. (See Darien.) Paterson's conduct on his return to Scotland was admirable. He set vigorously to work to frame a new plan for the colony; and wrote in 1701 an interesting work, hitherto attributed to the notorious John Law, entitled *Proposals and Reasons for constituting a Council of Trade.* On his return to London in 1701, he met with a friendly reception from King William; but the death of that monarch, shortly afterwards, cast a temporary cloud over Paterson's future prospects. He had an important share in the union of the English and Scottish Parliaments, as able tracts from his pen still attest; he was unremitting in his endeavours to relieve the distress of his native country; he had a sharp controversy with John Law on paper-money; and was elected member of Parliament for Dumfries in 1708. At the treaty of Union, an indemnity in favour of Paterson was recommended to Queen Anne by the Scottish Parliament, in consideration of his losses in connection with the Darien company, and of his "carrying on other matters of a public nature, much to his country's service." George I. had ascended the throne, however, before this indemnity was gained. The remainder of his years were spent at Westminster, in the metropolis, in unavailing hostility to the ruinous schemes of his relative and old financial foe John Law. Paterson died in January 1719. (See *William Paterson, the Merchant Statesman, and Founder of the Bank of England, his Life and Trials*, by S. Bannister, Edinburgh, 1858. Paterson's biographer, who has industriously collected all available information regarding him, also advertises *The Writings of William Paterson, with a Biographical Introduction*, 2 vols. 8vo, 1858.)

PATHOLOGY (πάθος, *suffering* or *disease*, and λόγος, *a discourse*) is properly, and in its widest sense, the science of disease. It is usually divided by scientific men into *general* and *special* pathology. The former includes, first, the more general principles relative to the primary elements of disease, including the various phenomena and causes of those derangements to which the animal economy is subject; and, second, the general facts or principles relative to the more obvious analogies of disease, derived from a comparative view of particular diseases. The latter or special division of pathology comprehends the consideration of particular diseases as they occur in nature. The French divide pathology into *external* and *internal*, employing those terms in a sense synonymous with what English writers usually call the principles and practice of surgery and physic. From whatever point of view, however, we regard the derangements of the animal frame, the objects of investigation are precisely the same. There are, *first*, the morbid phenomena symptomatic of derangement; *second*, the morbific agents by which derangements of the economy are liable to be produced; *third*, the more immediate seats, and the peculiar nature of each, of those derangements to which the system is liable; and, *fourth*, the morbid changes discoverable after death, whether as cause or as effect of certain derangements of functions known to exist during life. In short, pathology has for its bases the observation of the circumstances that precede a disease, of its symptoms when present, and especially the examination of the body after death. (See Medicine, and Physiology.)

PATIBULUM. See Furca.

PATMOS, one of the group of islands in the Ægean Sea which were called the Sporades, was situated to the south of Samos. Ancient writers represent it to have been about 30 Roman miles in circumference, and to have had a sea-port town of the same name as itself. It is celebrated

as the place where the apostle John endured banishment, and where he wrote the Apocalypse. The credulous point out a cave in which he is said to have sat while the heavenly visions passed before the eye of his imagination.

PATNA, a town of British India, capital of a district of the same name, in the presidency of Bengal, stands on the right bank of the Ganges, 10 miles E. of Dinapore, 157 E. of Benares, and 377 N.W. of Calcutta. The city and suburbs extend along the river to the length of 9 miles, and inland for about 2 miles; but the city itself, which is of a rectangular form and surrounded with walls, is only about a mile and a half in length, by three-quarters of a mile in breadth. When viewed from the water, the appearance of Patna is very beautiful, as there are then seen many large and handsome houses with flat roofs and carved balustrades, numerous temples and mosques, Saracenic arches and ancient towers; while many *ghats*, or flights of stairs, lead down to the Ganges; and in the background a range of heights closes in the view. There is one principal thoroughfare extending parallel to the river, between two gates in the eastern and western walls. This street is wide, though neither straight nor regular; but the other streets and lanes are very narrow and crooked. The better class of houses are built of brick, and have flat roofs and balconies; but a great number consist of little better than mud, and are covered with tiles or thatch. There are numerous mosques in the city, but the majority of them are treated with so little reverence or care, that they are used as warehouses,—a fate from which even the principal mosque, though a handsome building, is not exempt. The chief place of Mohammedan worship is in the west suburb, where vast multitudes of Mussulmans frequently congregate. In the same suburb are the residences of the Europeans, for the most part along the river's bank, but they are neither many in number nor splendid in appearance. A penitentiary and house of correction have recently been erected within the city; and there is also a school where the English language and literature, history and mathematics, are taught. The eastern suburb contains the principal market-place and several granaries. The manufactures of Patna are neither extensive nor important; but the bazaars are well supplied with domestic and foreign goods; and some trade is carried on in rice, opium, wheat, indigo, saltpetre, sugar, &c. During the summer the heat is very great, as the sun's rays are reflected from a bare and sandy island opposite the town. Patna is a place of great antiquity. Its old Sanscrit name was *Pataliputra*, and it is supposed to be the place mentioned by Greek and Roman writers under the name of *Palimbothra*. It was visited by Megasthenes, who went as an ambassador from Seleucus Nicator to Sandracottus, and who afterwards wrote an account of India. It is said to have been then 80 stadia in length and 15 in breadth, and surrounded with a stockade and ditch. It seems to have been at this time the capital of an independent state, but subsequently it formed part of the kingdom of Kunnouj, which was in early times one of the most powerful nations of India. In 1194 A.D. this kingdom was conquered and annexed to the empire of Delhi, of which Patna, along with the rest of Bengal and Behar, thenceforward formed a part. Factories were established here at an early period by the British, and a trade was carried on in rice and opium. In 1763 disputes began to arise between Meer Cossim, the nawaub of Bengal and Behar, and the servants of the East India Company, about the transit-dues levied on native traders, from which the English claimed exemption. The nawaub for some time refused to accede to these demands; but finally he entirely abolished all the imposts both on British and native goods, a step which was not desired by the Company, and which must have greatly diminished his revenues. In revenge for this injury, he proceeded in various ways to annoy the British; and at length went so far as to seize some of their boats on the Ganges. On this, Mr Ellis, the chief of the factory at Patna, made an attack on the city, and took possession of it, although Meer Cossim soon afterwards recovered it, and forced the British to take refuge in the factory. For four months hostilities continued between the two parties, in the course of which the nawaub was several times defeated, until he became so exasperated at the loss of the city of Monghyr, that he ordered the murder in cold blood of 200 prisoners. The grave of these prisoners is marked by a column in the city. On the 6th of November in the same year Patna was taken by the British; and in May 1764 Meer Cossim's troops were totally defeated under the walls. Since that time the place has remained undisturbed in the hands of the British. Pop. stated at 284,132.

PATNA, a district of British India, deriving its name from the above town, is bounded on the N. by the districts of Sarun, Tirhoot, and Monghyr; E. by that of Monghyr; S. by those of Monghyr and Behar; and W. by that of Shahabad; and extends from N. Lat. 25. 3. to 25. 38., E. Long. 84. 45. to 86. 10. Length, from E. to W., 85 miles; breadth, 45; area, 1828 square miles. The Ganges flows along its northern frontier; and the Son, a tributary of that river, forms the western boundary for a considerable distance. The chief of the other rivers are the Poonpoon and the Lesser Poonpoon; but during the rainy seasons the whole country is intersected with streams. The soil is very fertile and well cultivated: rice, wheat, and barley are grown in abundance; and many groves and orchards diversify the aspect of the country. The climate is very hot in summer, but the winters are mild. The district is traversed by the East India Railway, and by several roads. Pop. 1,200,000.

PATRAS (anciently *Patræ*), a fortified town of Greece, capital of the monarchy of Achaia and Elis, stands on the E. side of the gulf of the same name, near the entrance of that of Corinth, 10 miles S.S.W. of Lepanto. It is built partly on a plain and partly on the slope of a hill, on the summit of which stands a castle. The principal streets are broad, straight, and regular; and many of the houses are large, well-built, and surrounded with gardens, but they are generally but of one storey high, on account of the frequency of earthquakes. The only important buildings besides the castle, which is very strong, are the barracks, military hospital, and churches. An active trade is carried on with the Ionian Islands, Italy, Marseilles, &c.; the chief exports being corn, wine, oil, currants, and other fruits; silk, cotton, wool, &c. The number of vessels that cleared from the port in 1854 was 439; tonnage, 34,616; value of cargoes, L.100,570: in 1855,—vessels, 609; tonnage, 53,684; value of cargoes, L.251,994. The number of vessels that entered in 1854 was 443; tonnage, 52,573; value of cargoes, L.64,002: in 1855,—vessels, 571; tonnage, 42,914; value of cargoes, L.123,828. The harbour is not safe, being exposed to a heavy sea; but there is a mole at some distance from the town, where vessels can lie close to the wharf. The ancient Patræ was founded by the Ionians; and on their expulsion from the Peloponnese, was occupied by the Achæans, from one of whom, called Patreus, it is said to have derived its name. In the Peloponnesian war Patræ embraced the side of the Athenians; and, on the advice of Alcibiades, the city and port were connected by walls. It afterwards was one of the cities of the Achæan League, but remained comparatively insignificant till the time of Augustus. That monarch, after the battle of Actium, made Patræ a Roman colony, and gave it the dominion over the neighbouring towns. In the time of Pausanias the town contained a theatre, music-hall, numerous temples, and other buildings. Patræ was a dukedom under the Byzantine empire, but was sold to the Venetians in 1408, and taken by the Turks in 1446, who, though the

Venetians recovered it for a short time in 1533, continued to hold it till the Greek revolution. The war which then took place considerably injured the prosperity of the town. The citadel was held for a long time by the Turks, who, after repeated assaults of the Greeks, at length capitulated in 1828. Since that period it has recovered much of its former prosperity, and is now the most important town in the Morea. Pop. 10,000.

PATRIARCH (πατήρ, *a father*, and ἄρχω, *I govern*) is a title applied to the heads of families in early history, and especially to the ancestors of the Israelites from Adam to Jacob, and to his twelve sons in particular. The name was kept up among the Jews after the dispersion; and Hillel the Babylonian is said to have been the first of the *Jewish patriarchs*. The principal business of this class seems to have been the instruction of the people.

The title of *Patriarch* was also assumed in the Christian church about the fourth century by the bishops of the principal cities of the Roman empire, such as Rome, Constantinople, Alexandria, and Antioch. The patriarchate of Constantinople swallowed up those of Antioch and Alexandria; and the Bishop of Constantinople assumed the title of "Universal Patriarch." The Bishop of Rome in turn bore the name of "Prince of the Patriarchs;" and the struggle which ensued between the two rival ecclesiastics led to the separation of the Eastern and Western Churches.

PATRICIANS (*patricii*, from *pater*, a father) was the name given among the Romans to the original *gentes*, of which the *populus Romanus* was composed, or to their descendants by blood or adoption. *Patricii* and *patres* were originally convertible terms, and have essentially the same meaning. During the period of Roman history extending from the building of the city to the formation of the *plebs* as a distinct order of citizenship, Niebuhr has satisfactorily shown that the patricians and the *populus Romanus* were in point of fact identical. The earlier inhabitants of the places occupied by the sovereign people were reduced to a state of servitude, and are known by the names *cliens* and *plebs*; but the conquering race were all regarded as patricians or burghers, from whom a select body of senators was chosen as their representatives. The amalgamation of the Latin, Sabine, and Etruscan tribes gradually gave rise to the distinction of *patres majorum gentium* and *patres minorum gentium*, the latter epithet being employed to designate those recently elevated to a rank of equality with the old privileged patrician class forming the *populus Romanus*. The one class was created by Romulus, the other by Tarquinius Priscus. During this period every Roman citizen was a patrician, and, in contrast with the client beneath him, an aristocrat.

The aristocracy was not certainly exclusive in those days, when every citizen could claim the honour; but in the succeeding period, dating from the creation of the plebeian order to the reign of Constantine, the patricians became a genuine aristocracy of birth. The sovereign people no longer consisted exclusively of the patricians, but of the populus (or patricians) and the plebs. In course of time, however, this distinction well nigh ceased; and the term *populus* came to denote the entire body of Roman citizens, including both patricians and plebeians. During the reign, again, of the Antonines, the patricians were not included under the populus, but formed an exclusive aristocratic class, which no power could degrade to the plebeian level, except the free-will of the patrician himself. The first centuries of this period witnessed a constant struggle for ascendancy between the patricians and plebeians. The former class strove to monopolize all the great offices, both civil and religious, of the nation. In this they generally succeeded; but the upshot of the contest was the establishment of the political equality of the two rival orders, and the consequent partition of the political and religious honours of the state.

From the reign of Constantine downwards, the patrician dignity ceased to be hereditary, and became an exclusively personal distinction, bestowed irrespectively on those individuals who had done the emperor or the empire good service. Old Roman families could claim no share, as such, in the new patrician dignity created at Constantinople. It elevated the individuals honoured with it to the highest rank in the state next to the consuls; and, unlike the old Roman order, the modern patricians were distinguished from the ordinary citizens by their dress and equipage. The honour was not hereditary, however, and was but warily bestowed by the emperors.

In this, as in other matters, the Popes, when they came to power, imitated the imperial right of temporal sovereigns in bestowing the patrician rank on persons deemed worthy of the distinction. In several European kingdoms also the sovereigns imitated the ancient custom of honouring certain distinguished subjects with the title of *patricius*. In certain parts of Italy, the term *patrician* is still applied to the hereditary nobility. (See Niebuhr's *History of Rome*, vol. ii.; Becker's *Handbuch der Rom. Alterth.*, vol. ii.; Ersch und Gruber's *Encyclopadie*, v. "Patricier;" Smith's *Dict. of Gr. and Rom. Antiquities*; and Adam's *Roman Antiquities*.)

PATRICK, St, the apostle and the second bishop of Ireland, is supposed to have been born on the 5th of April 373, of a good family, at Kirkpatrick, near Dumbarton in Scotland. During some inroad of certain exiles from Ireland he was taken prisoner, and carried into that kingdom. After serving there for six years, and making himself master of the Irish language, he effected his escape, and returned home. It was about two years afterwards that he formed the design of converting the Irish. Repairing to the Continent to qualify himself for this undertaking, he studied under his mother's uncle, St Martin, Bishop of Tours, who ordained him deacon, and under St German, Bishop of Auxerre, who ordained him priest. Pope Celestine then consecrated him bishop, changed his name into Patricius or Patrick, and gave him a commission to evangelize the Irish. The new apostle reached his destination in 432, and landing, as some suppose, at Wicklow, proceeded to convert and baptize the natives. After labouring seven years indefatigably in this great work, he returned to Britain, which he delivered from the heresies of Pelagius and Arius. He then visited the Isle of Man, which he converted in 440. His return to Ireland took place in 448; and in thirteen years more the conversion of the whole island was completed. The remainder of his career was spent in superintending the monasteries of Armagh and Saul, which he had founded. After having established schools and an academy, he closed his life, in the 120th year of his age, in 493, and was buried at Down (now Downpatrick), in the same grave with St Bridget and St Columba. The genuine Works of St Patrick were collected and printed by Sir James Ware, 1656. There are no fewer than seven lives of the Irish apostle published in Colgan's *Acta Triadis Thaumaturgæ*. (See also *Annals of the Kingdom of Ireland*, by the Four Masters, edited by O'Donovan, Dublin, 1851.)

PATRICK, *St*, *Order of*, an institution of knighthood, founded in Ireland by Geo. III. on February 5, 1783. "The most illustrious Order of St Patrick" consists of the sovereign, a grand master (viz., the lord-lieutenant for the time being), and twenty-two knights.

PATRICK, *Simon*, a learned English bishop, and author of a number of useful works in practical divinity, was born at Gainsborough in Lincolnshire in 1626. He entered Queen's College, Cambridge, in 1644; and after taking orders, he became successively chaplain to Sir Walter St John, and vicar of the church at Battersea in Surrey. He

was afterwards preferred to the rectory of St Paul's, Covent Garden, London, where he continued during the plague of 1665 amongst his parishioners. In 1668 he published his *Friendly Debate between a Conformist and a Nonconformist.* This was answered by the dissenters, whom he had much exasperated; but by his moderation and candour towards them afterwards, they were greatly reconciled to him; and he is said to have gained over many of them to the communion of the Established Church. He was made dean of Peterborough in 1678, bishop of Chichester in 1689, and bishop of Ely in 1691. In 1689 he was employed, with others of the new bishops, to settle the affairs of the church in Ireland. He died in 1707.

Bishop Patrick's sermons and devotional writings are very numerous. In this species of composition he was considered one of the happiest authors of his time; and his writings are still esteemed by pious Christians. His *Commentary on the Historical and Poetical Books of the Old Testament*, 14 vols. 4to and 8vo, London, 1695, &c., is the result of extensive reading, and, without being highly critical, continues to be one of the best in the language for practical purposes. He proceeded no farther than the Song of Solomon; and the commentaries of Lowth, Arnald, Whitby, and Lowman are generally added to complete the work. (See a new edition, with the text printed at large, in 4 vols. imp. 8vo, 1853.) His works have never been published in a collected form; but a complete list of them will be found in Darling's *Cyclopædia Bibliographica*, London, 1854. An autobiography of the bishop appeared at Oxford in 18mo, 1839.

PATROCLUS, a Grecian chief, was the son of Menœtius of Opus. His fame was chiefly owing to his intimate connection with Achilles. He was first the playmate of the rising hero at the court of Phthia. Then, actuated by pure motives of affection, he became his companion in arms at the siege of Troy. He slept in his tent at night, he fought at his side during the day, and when the great champion absented himself from the field in a fit of peevishness, the inseparable friend stayed at home to keep him company. Nor was this connection severed by the approach of death. Patroclus received his fatal wound from Hector in the armour of Achilles; his tomb was soon re-opened to receive the ashes of "great Thetis' son;" and the two are said to have met each other and renewed their friendship in the lower world.

PATROL, in war, a round or march made by the guards or watch in the night-time, to observe what passes in the streets, and to secure the peace and tranquillity of a city or camp. The patrol generally consists of a body of five or six men, detached from a body on guard, and commanded by a serjeant.

PATRON (*patronus*, from *pater*, a father) was an appellation given by the Romans to a master who had freed his slave. As soon as the relation of master and slave expired, that of patron and freedman (*libertus*) began. The connection, as the name implies, was something analogous to that of father and son. The Romans, in giving their slaves their freedom, did not despoil themselves of all rights and privileges in those manumitted; the law still subjected them to considerable services and duties towards their patrons, the neglect of which was very severely punished. The most important part, however, of the relation between the patronus and the libertus was the right of the former, in certain cases, to the whole or part of the property of his freedman at his death. The libertus was also regarded as the *cliens* of his patron. (See CLIENT.) *Patrona* was the name borne by a female who had a freedwoman (*liberta*); but the laws regulating their connection differed in some points from those affecting the *patronus* and *libertus*.

Any Roman citizen desirous of a protector might attach himself, as client, to any patron he chose. Patron was thus not necessarily limited to the relation of patron and freedman. The patron and client were mutually attached and mutually obliged to each other; and by this means, in consequence of reciprocal ties, all those seditions, jealousies, and animosities, which were sometimes the effect of a difference of rank, were prudently avoided. For it was the duty of the patron to advise his clients in points of law, to manage their suits, to take care of them as of his own children, and secure their peace and happiness. The clients were to assist their patrons with money on several occasions; to ransom them or their children when taken in war; to contribute to the portions of their daughters; and to defray, in part, the charges of their public employments. The patron and client were never to accuse each other, or take contrary sides; and if either of them was convicted of having violated this law, the crime was equal to that of treason, and any one was allowed to kill the offender with impunity. This patronage was a tie as effectual as any consanguinity or alliance, and had a wonderful effect towards maintaining union and concord amongst the people for the space of six hundred years, during which time we find few dissensions or jealousies between the patrons and their clients, even in the times of the republic, when the populace frequently mutinied against those who were most powerful in the city.

PATRON, in the Church of Rome, a saint whose name a person bears, or under whose protection he is placed, and whom he takes particular care to invoke; or a saint in whose name a church or order is founded.

PATRONYMIC (πατήρ, *a father*, and ὄνομα, *a name*) signifies properly a name taken from one's father, and is applied by grammarians to such names of men or women as are derived from those of parents or ancestors. Patronymics are derived from the father, as Pelides,—that is, Achilles, the son of Peleus; or from the mother, as Philyrides,—that is, Chiron, the son of Philyra; or from the grandfather on the father's side, as Æacides, or Achilles, the grandson of Æacus; or from the grandfather by the mother's side, as Atlantiades, Mercury, the grandson of Atlas; or, lastly, from the kings and founders of nations, as Romulidæ, the Romans, so called from their founder King Romulus. The terminations of Greek and Latin patronymics are chiefly four,—viz., *des*, of which we have already given examples; *as*, as Thaumantias,—that is, Iris, the daughter of Thaumas; *is*, as Atlantis,—that is, Electra, the daughter of Atlas; and *ne*, as Nerine, the daughter of Nereus. Of these terminations, *des* is masculine, and *as*, *is*, and *ne* are feminine; *des* and *ne* are of the first declension, *as* and *is* of the third. In Greek, and particularly in Sanscrit, patronymics are very numerous. There are very few patronymics in English, and those are chiefly of Celtic origin, as names formed by the addition of *Mac* or of *O'*. The termination *son* (as *John-son*) is also a frequent mode of forming patronymics in English names. English patronymics are, however, already fixed, and are no longer in process of formation.

PATTA, or PATA, a town of Africa, on an island off the E. coast, in S. Lat. 2. 8., E. Long. 41. It is separated from the mainland by a narrow channel, navigable only for boats; and seems to have been formerly a much more important place than at present. It is composed of scattered huts of an oblong form, built of stakes and reeds plastered over with mud. The Portuguese formerly built a castle here; but they were driven out by the natives, who subsequently became subjects of the Imam of Muscat. They wear long white garments and white embroidered turbans, and are armed with sabres and daggers. A considerable coasting trade is carried on. Pop. about 4000.

PATTI, a town of Sicily, province of Messina, on the northern coast of the island, 15 miles S.W. of Melazzo, and 33 W.S.W. of Messina. It is well built, with broad and regular streets; and contains a cathedral, the ruins of a fine

abbey, and a house of refuge. Earthenware is made here; and fishing is carried on. Pop. 6000.

PAU, a town of France, capital of the department of Lower Pyrenees, stands on a ridge of hills on the right bank of the Gave de Pau, 58 miles E.S.E. of Bayonne, and 468 S.W. of Paris. Its situation is very beautiful, as the river has its banks lined with trees, and is crossed by a picturesque bridge; while the view to the south is extremely fine, commanding the bold and serrated range of the Pyrenees, appearing in the distance between the gaps in the rounded and wooded hills that rise in front. The town is well and regularly built, having one principal street, several squares, and public walks. The Place Royale, near the centre, is planted with trees, and contains a statue of Henri IV.; the Place de la Comedie is also a fine square; but the most beautiful public place is the Parc, a natural terrace shaded with fine trees, which extends along the bank of the Gave de Pau. The most remarkable building in the town is the castle, a large irregular structure with five towers, standing at the west end, overlooking the river. This castle is interesting on accouut of its historical associations; for Henri IV. was born here, and his cradle, consisting of a large tortoise-shell, is still preserved. The castle was much injured during the first revolution, when it was used for barracks; but it was handsomely restored by Louis Philippe, and was for some time the residence of Abd-el-Kader. There are in Pau, Roman Catholic and Protestant churches, courts of law, a college, museum, public library, literary society, and market-house. The manufactures consist of handkerchiefs, table linen, carpets, rags, leather, and paper. A considerable trade is carried on in wine, chestnuts, hams, salt meat, cotton and woollen goods, &c. Pau is a favourite residence of the English, especially in winter, on account of the mildness and dryness of the climate. It is also much resorted to by the Parisians. Bernadotte, the King of Sweden, as well as Henri IV., was born here. Pop. (1856) 17,238.

PAUL, originally SAUL, an apostle of Jesus Christ, and author of several portions of the New Testament canon. Though a native of Tarsus, a city of Cilicia,[1] he was the son of Jewish parents belonging to the tribe of Benjamin.[2] From his father he inherited the rights of Roman citizenship,[3] which had probably been conferred upon some of his ancestors for some important services rendered to the commonwealth;[4] and it has been conjectured, though with no great probability, that the cloak and parchments which he so earnestly charged Timothy to bring with him to Rome were the Roman toga and the certificates of his citizenship, which he expected might be of use to him in his anticipated trial before the emperor. The name *Saul* (שׁאוּל), which he received at his birth, and which signifies "the longed-for, the desired," would seem to indicate that he was the first-born son of his parents, and that his birth was viewed by them as an answer to prayers; that he was not, however, their only child, is apparent from Acts xxiii. 16, where mention is made of his "sister's son." In the 16th chapter of the Epistle to the Romans he himself names six persons whom he styles his *συγγενεῖς*; but it has been questioned whether by that term he intends more than *fellow-countrymen*, though the probability is, he uses it in its proper sense of *relations*.[5] The name Saul (שׁאוּל) was afterwards dropt, and that of Paul (Παῦλος) constantly used both by himself and others. Much difference of opinion exists as to the relation of these names to each other, and the reason why the one was dropt and the other retained. Some think that, as Luke mentions the name *Paul* for the first time in connection with the apostle's interview with Sergius Paulus (Acts xiii. 9), the apostle assumed that name out of courtesy to the proconsul; an opinion which, though suggested by Jerome, and adopted by Bengel, Olshausen, Meyer, and Baumgarten, does not in itself seem very probable, and is hardly in keeping with the form of Luke's statement, "Saul, who is also Paul." Others with greater probability suppose that the apostle had originally a double name, the one Hebrew and the other Latin; and that when he came to labour chiefly among the Gentiles, he dropt the former and used only the latter. So Alting, Lightfoot, Hammond, Wolf, Basnage, Schrader, Winer, De Wette, and others. In the judgment of many distinguished scholars, however, the most probable conjecture is, that the name Paulus is only a softened form of the Hebrew, Shaool, to accommodate it to western organs, just as we find Jason for Jesus, Hierosolyma for Yerushalayim, Matthæus for Mattiyah, Alphæus for Chalpai, and many others; though it must be confessed that none of these is exactly parallel to the case before us.

His father being of the sect of the Pharisees, probably devoted him from his infancy to the service of religion; and with this view Paul seems to have received such education as appeared most calculated to fit him for the duties to which he was destined. At that time Tarsus was eminently distinguished for its cultivators of philosophy, and every other department in the circle of instruction (*σπουδὴ πρὸς τε φιλοσοφίαν καὶ τὴν ἄλλην ἐγκύκλιον ἄπασαν παιδειάν*);[6] but to what extent the future apostle of Christianity was indebted to the labours of such teachers for his early education no means are left us of judging. It is probable that his obligations were not very great; for as his ultimate destination was to the office of an expounder of the Jewish law and traditions, it does not appear likely that he would be sent by his parents to occupy himself with the literature and philosophy of those whom the Jews despised as outcasts, as well from the light as from the favour of heaven. At the same time it cannot be denied that his residence in a city where the study of the liberal sciences was so assiduously and successfully prosecuted as to place it upon a par with "Athens, Alexandria, or any other place that could be named in which schools and studies are to be found,"[7] must have had a considerable influence in refining his taste and liberalizing and expanding his views; and he would doubtless here also obtain a familiarity with Greek as a spoken language which could not but be of use to him in after-life. It was at Jerusalem, however, the centre of the Jewish world, that the most important part of his education was received. At an early age, in his twelfth or fourteenth year, as is supposed,[8] he was brought to this city, and placed under the instruction of Gamaliel, one of the most famous teachers of Jewish learning at that time.[9] Here he finished his education as a Pharisee, and at the same time, according to the custom of the Jews, acquired a mechanical art, that of a *σκηνοποιός*, which some render "a mechanist;"[10] others "a haircloth-maker;"[11] others "a maker of tapestry or carpeting;" and others, with most apparent propriety, as in our version, "a tentmaker, or a maker of tent-cloth."[12] By this he probably supported himself during

[4] The opinion, that the natives of Tarsus enjoyed the *jus civitatis* as a birthright, is not supported by evidence. The fact of that city's having been created by Augustus an *urbs libera* (Plin. v. 27) does not lead to any conclusion as to the possession by its natives of the right of Roman citizenship; and, from Acts xxi. 39, compared with xxii. 24, 27, it may be inferred, that as the chief captain knew Paul to be a native of Tarsus, and yet was ignorant of his Roman citizenship, these two were not necessarily conjoined.

the time he was engaged in the prosecution of his studies, as we know he was in the habit of doing at an after period whilst engaged as an apostle. How long he abode in Jerusalem at this time, or whether he returned to Tarsus at all before his conversion, are points on which no certain information can now be obtained. In the history of the early church, he is introduced to us for the first time[1] as "a young man,"[2] whose zeal for the religion of his fathers had prompted him to assume the character of an active persecutor of those who had forsaken that religion for the faith of Christ. On the occasion of the martyrdom of Stephen, he appears in the capacity of an abettor, and in some respects a sort of superintendent, of the act; and immediately after this he, as if rendered more ferocious by the blood he had assisted in shedding, kindled the flames of a relentless and unsparing persecution, in which all, without respect of age or of sex, who had professed the hated religion, were compelled to blaspheme the name of Jesus, or obliged to endure the utmost indignities and the most condign punishments.[3] It was whilst engaged in these cruel efforts of a dark and bigoted zeal that he was made to experience that extraordinary change of opinion and feeling which gave a new direction to all his energies, and led him to devote his life to the advancement of that cause which he at first deemed it serviceable to God to oppose and destroy. Having obtained from the rulers of his nation a commission to go to Damascus, in which city the Jews were very numerous, and where also the new religion had obtained a footing, for the purpose apparently of arresting such of the Christians as had fled to that city, and bringing them back bound to Jerusalem, he was himself arrested by a higher power, and made to feel his utter impotency when attempting to oppose the cause of Christ. Whilst crossing the plain to the south of Damascus, about noon-day, and at a short distance from that city, he was suddenly surrounded by a miraculous light from heaven, which had the effect of so paralyzing him, that he fell to the ground, whilst a voice addressed to him the thrilling question, "Saul, Saul, why persecutest thou *me?*" In answer to the inquiry which he made in return, the speaker said, "I am Jesus of Nazareth, whom thou persecutest; but arise and go into the city, and it shall be told thee what to do." Confounded, humbled, and agitated, he obeyed the heavenly vision; and as the brilliancy of the light had obscured his eye-sight, he was led by his astonished attendants into the city, where he remained in a state of deep dejection for three days and nights, during which he tasted neither meat nor drink. From this painful condition he was relieved by the visit of a man named Ananias, who, at the command of Christ, sought him out, welcomed him as a brother, and baptized him into the profession of Christianity.[4]

By the majority of Christians this narrative is accepted

---

[1] Acts vii. 58.

[2] Nothing decisive, however, can be drawn from this as to Paul's age at this period, for the word νεανίας is applied with much indefiniteness to persons of from twenty-four to upwards of thirty years of age. Perhaps his age was about thirty. He would hardly have been in the confidence of the Sanhedrim had he been younger.

[3] Acts viii. 1–3, xxvi. 10, 11.

[4] Acts ix 1-18. The conversion of such a man, at such a time, and by such means, furnishes one of the most complete proofs that have ever been given of the divine origin of our holy religion. That Saul, from being a zealous persecutor of the disciples of Christ, became all at once a disciple himself, is a fact which cannot be controverted without overturning the credit of all history. He must therefore have been converted in the miraculous manner in which he himself said he was, and of course the Christian religion be a Divine revelation; or he must have been either an impostor, an enthusiast, or a dupe to the fraud of others. There is not another alternative possible. The following is the substance of Lord Lyttleton's argument on this subject.

If he was an impostor, who declared what he knew to be false, he must have been induced to act that part by some motive. But the only conceivable motives for religious imposture are, the hopes of advancing one's temporal interest, credit, or power; or the prospect of gratifying some passion or appetite under the authority of the new religion. That none of these could be St Paul's motive for professing the faith of Christ crucified, is plain from the state of Judaism and Christianity at the period of his forsaking the former and embracing the latter faith Those whom he left were the disposers of wealth, of dignity, of power, in Judea; those to whom he went were indigent men, oppressed, destitute of all means of improving their fortunes. The certain consequence, therefore, of his taking the part of Christianity was the loss not only of all he possessed, but of all hopes of acquiring more; whereas, by continuing to persecute the Christians, he had hopes, rising almost to a certainty, of making his fortune by the favour of those who were at the head of the Jewish state, to whom nothing could so much recommend him as the zeal which he had shown in that persecution. As to credit or reputation, could the scholar of Gamaliel hope to gain either by becoming a teacher in a college of fisherman? Could he flatter himself that the doctrines which he taught would, either in or out of Judea, do him honour, when he knew that "they were to the Jews a stumbling-block, and to the Greeks foolishness?" Was it, then, the love of power that induced him to make this great change? Power! over whom? over a flock of sheep whom he himself had assisted to destroy, and whose very Shepherd had lately been murdered? Perhaps it was with the view of gratifying some licentious passion, under the authority of the new religion, that he commenced a teacher of that religion. This cannot be alleged, for his writings breathe nothing but the strictest morality, obedience to magistrates, order, and government, with the utmost abhorrence of all licentiousness, idleness, or loose behaviour, under the cloak of religion. We nowhere read in his works that saints are above moral ordinances; that dominion is founded in grace; that monarchy is despotism which ought to be abolished, that the fortunes of the rich ought to be divided amongst the poor; that there is no difference in moral actions; that any impulses of the mind are to direct us against the light of our reason and the laws of nature; or any of those wicked tenets by which the peace of society has been often disturbed, and the rules of morality often broken, by men pretending to act under the sanction of divine revelation. He makes no distinctions, like the impostor of Arabia, in favour of himself; nor does any part of his life, either before or after his conversion to Christianity, bear any mark of a libertine disposition. As amongst the Jews, so amongst the Christians, his conversation and manners were blameless. It has been sometimes objected to the other apostles, by those who were resolved not to credit their testimony, that having been deeply engaged with Jesus during his life, they were obliged, for the support of their own credit, and from having gone too far to return, to continue the same professions after his death: but this can by no means be said of St Paul. On the contrary, whatever force there may be in that way of reasoning, it all tends to convince us that St Paul must *naturally* have continued a Jew, and an enemy to Christ Jesus. If *they* were engaged on one side, *he* was as strongly engaged on the other. If shame withheld them from changing sides, much more ought it to have stopped him, who, from his superior education, must have been vastly more sensible to that kind of shame than the mean and illiterate fishermen of Galilee. The only other difference was, that *they*, by quitting their Master after his death, might have preserved themselves; whereas *he*, by quitting the Jews, and taking up the cross of Christ, certainly brought on his own destruction.

As St Paul was not an imposter, so it is plain he was not an enthusiast. Heat of temper, melancholy, ignorance, and vanity, are the ingredients of which enthusiasm is composed; but from all these, except the first, the apostle appears to have been wholly free. That he had great fervour of zeal, both when a Jew and when a Christian, in maintaining what he thought to be right, cannot be denied; but he was at all times so much master of his temper as, in matters of indifference, to "become all things to all men," with the most pliant condescension bending his notions and manners to theirs as far as his duty to God would permit; a conduct compatible neither with the stiffness of a bigot nor with the violent impulses of fanatical delusion. That he was not melancholy is plain from his conduct in embracing every method which prudence could suggest to escape danger and shun persecution, when he could do it without betraying the duty of his office or the honour of his God. A melancholy enthusiast courts persecution, and when he cannot obtain it, afflicts himself with absurd penances; but the holiness of St Paul consisted only in the simplicity of a godly life, and in the unwearied performance of his apostolical duties. That he was ignorant no man will allege who is not grossly ignorant himself; for he appears to have been master

as literally true, the scene being regarded as one of a miraculous kind, in which, by supernatural means, a manifestation of Jesus Christ was made to Paul. Opposed to this is the view of those who think that the whole passed in the mind of the apostle, and was the result either of a Divine operation exerted on him, or of the mere working of his own mind under deeply-excited feeling. Of those who take the latter view, some contend that the sudden light which shone around the apostle and his companions, and the sound which they heard and took to be a voice from heaven, are to be resolved into a sudden flash of lightning accompanied by thunder, which, by some pre-established harmony, conveniently took place just as the apostle's own reflections had reached the point of overwhelming him with shame and regret for his past conduct; whilst others regard all this as the mere drapery in which the story came to be dressed in the superstitious imaginations of the Christians. If the historical truth of the narrative is to be denied, the latter is undoubtedly the preferable hypothesis; for it seems very absurd to resort to the supposition of a natural phenomenon of which there is no mention, for the purpose of saving the historical character of the narrative in a minor point, whilst, as regards its principal matter, it is to be rejected as false. But if this story is a mere myth, how came Paul to tell it as a fact? Or how came so simple a matter as the conversion of a bigoted Jew to Christianity, an event of which the instances were of almost daily occurrence, to be invested in the minds of the Christians in this particular case with so much of supernatural "drapery?" It is evident that Paul himself believed the whole transaction to have happened as it is related by Luke; for, many years afterwards, we find him not only repeating the story, but affirming that his companions were witnesses of the outward phenomena of the scene (Acts xxii. 6–10). In this case there is evidently no alternative but to admit the whole as historical, or to reject the whole as a vain hallucination or an impudent falsehood.

The first three years after his conversion were spent by Paul in Arabia,[1] where he received, "by revelation from Christ," that doctrine in all its fulness which he afterwards preached, and where, in solitude and quiet, he was doubtless engaged in training himself for the work in which he was about to engage. On his return to Damascus, he openly appeared as a preacher of Christianity, a circumstance which the Jews felt to be so injurious to their cause, that they sought, by the aid of the governor, who was in all probability himself a Jew, to put him to death. Having, by the aid of his Christian brethren, escaped their malice, he betook himself to Jerusalem, where, after the fears of the brethren, who remembered his former enmity, but had not heard of his subsequent conversion to Christianity, had been removed by the testimony of his friend and companion Barnabas, he was gladly welcomed amongst them, and permitted to occupy that rank to which Christ had called him.[2] Whilst at Jerusalem on this occasion, he fell into a trance in the temple, and had a vision of Christ, who commanded him to go forth as the apostle of the Gentiles (Acts xxii. 17–21). It is probably to this that he alludes in 2 Cor. xii. 1–9, though there are difficulties in the way of this conclusion.[3] The enmity of the Jews again compelled him to change his residence. After being fifteen days in Jerusalem, he went to Cæsarea, and thence to his native city Tarsus, where he abode for several years.[4] In the meantime, Christianity, which had hitherto been preached only to the Jews, had received some adherents from amongst the Gentiles at Antioch; and this led to the mission of Barnabas from Jerusalem, for the purpose of instructing and regulating the church that had been formed there. Barnabas, after some time, finding the need of assistance and counsel, went to Tarsus, and returned with Paul to Antioch, where they abode for a year occupied in united efforts for the promulgation of Christianity. At the close of that period, they were sent to Jerusalem by the Christians at Antioch with the contributions which had been made by them on behalf of their brethren in Judea, who were suffering from the effects of a dearth.[5] This was Paul's *second* visit to Jerusalem since his conversion. After some months, they again returned to Antioch, accompanied by John Mark, the nephew of Barnabas. The cause of Christianity by this time had begun to flourish in that city, and several persons had been received into the church who were qualified to act as teachers to the rest. This rendered it the less necessary that Paul and Barnabas should remain any longer with them; and accordingly, shortly after their return, the church received a special command from heaven to set them apart to general missionary work. In obedience to this command, they were sent forth; and, accompanied by John Mark, who, however, soon deserted them and returned to Jerusalem, they visited Seleucia, Cyprus, Perga in Pamphylia, Antioch in Pisidia, Iconium, Lystra and Derbe, cities of Lycaonia. At Lystra, in consequence of Paul's curing a cripple, the people were on the point of offering him and his companion divine honours, under the impression that the gods had come down in the likeness of men, but were restrained by the vehement expostulations of those for whom these impious honours were designed; and in a few days after, they had so completely changed their minds, that, at the instigation of the Jews, they stoned Paul, and left him for dead. Retracing their steps, they returned by way of Attalia, a

not only of the Jewish learning, but also of the Greek philosophy, and to have been very conversant even with the Greek poets. That he was not credulous is plain from his having resisted the evidence of all the miracles performed on earth by Christ, as well as those that were afterwards worked by the apostles, to the fame of which, as he lived in Jerusalem, he could not possibly have been a stranger. And that he was as free from vanity as any man that ever lived may be gathered from all that we see in his writings or know of his life. He represents himself as the least of the apostles, and not meet to be called an apostle. He says that he is the chief of sinners; and he prefers, in the strongest terms, universal benevolence to faith, and prophecy, and miracles, and all the gifts and graces with which he could be endowed. Is this the language of vanity or enthusiasm? Did ever fanatic prefer virtue to his own religious opinions, to illuminations of the Spirit, and even to the merit of martyrdom.

Having thus shown that St Paul was neither an impostor nor an enthusiast, it remains only to be inquired whether he was deceived by the fraud of others; but this inquiry needs not be long, for who was to deceive him? A few illiterate fishermen of Galilee? It was *morally* impossible for such men to conceive the thought of turning the most enlightened of their opponents and the most cruel of their persecutors into an apostle, and to do this by a fraud in the very instant of his greatest fury against them and their Lord. But could they have been so extravagant as to conceive such a thought, it was *physically* impossible for them to execute it in the manner in which we find his conversion to have been effected. Could they produce a light in the air which at mid-day was brighter than the sun? Could they make Saul hear words from out of that light which were not heard by the rest of the company? Could they make him blind for three days after that vision, and then make scales fall off from his eyes, and restore him to sight by a word? Or could they make him, and those who travelled with him, believe that all these things had happened, if they had not happened? Most unquestionably no fraud was equal to all this.

Since, then, St Paul was neither an impostor, an enthusiast, nor deceived by the fraud of others, it follows that his conversion was miraculous, and that the Christian religion is a divine revelation.

St Paul. city of Pamphylia, by sea to Antioch, where they rehearsed to the church all that God had done by them. This formed the apostle Paul's *first* great missionary tour.[1]

After some time spent at Antioch, he and Barnabas again went up to Jerusalem, for the purpose of consulting the apostles and elders in regard to some dissensions which had occurred in the church at Antioch as to the obligation on Gentile converts of the Mosaic ceremonial. This gave occasion to the holding of a council at Jerusalem, at which, after much disputing, it was at length agreed unanimously, on the suggestion of the apostle James, that they should lay no stumbling-block in the way of their Gentile brethren, by requiring of them more than simply that they should abstain from meats offered to idols, from uncleanness, from things strangled, and from blood, whether pure or mixed with anything else. A letter to this effect was written to the church at Antioch in the name of the church at Jerusalem; and with this two of the members of this church, Judas and Silas or Silvanus, were appointed to accompany Paul and Barnabas to Antioch.[2] By these means the difference of opinion amongst the brethren was removed, and the church restored to peace. This led Paul to propose to Barnabas another missionary tour, to which that faithful fellow-labourer having consented, they were on the verge of departure, when an unhappy contention, arising out of a determination on the part of Barnabas to take with them his nephew John Mark, a step which Paul firmly resisted on the ground of Mark's former conduct in deserting them, produced a rupture between these two eminent individuals, and led to their prosecuting a separate course.[3] Whilst Barnabas, in company with his nephew, went to Cyprus, Paul, attended by Silas, went towards the east, and, passing through Syria and Cilicia, revisited the scenes of his former labours and sufferings in Lycaonia. At Lystra he found Timothy, a young man, a native of Derbe (Acts xx. 4), who had been probably converted to Christianity on the occasion of the apostle's former visit, and who was so highly commended by the Christians in that district that Paul selected him as the companion of his travels, having previously ordained him by the imposition of hands.[4] Accompanied by him and Silas, the apostle next passed through the region of Phrygia and Galatia, and avoiding Asia strictly so called, which he was forbidden by the Holy Spirit to enter, as well as Bithynia, they came by way of Mysia to Troas, a city and port on the borders of the Hellespont. Here he was directed by an apparition in a vision to go into Macedonia; and accordingly, with his companions, having crossed to Samothracia, and thence to Neapolis, a seaport of Thrace, he arrived in due course at Philippi. Here they remained for some time, and made many converts; amongst others, the jailor of the prison into which Paul and Silas had been thrust after having been scourged, in consequence of a charge which had been brought against them as disturbers of the peace of the city, by a set of imposters whose trade they had destroyed by expelling an evil spirit from a female slave who brought them much gain by her skill in soothsaying. From Philippi they passed through Amphipolis and Apollonia, cities of Macedonia, to Thessalonica, where, though they abode only a short time, they preached the gospel with great success. A tumult having arisen at the instigation of the Jews, the Christian converts, fearing for their safety, sent them by night to Berea, another city of Macedonia, about 40 miles west of Thessalonica, where they were favourably received by their Jewish brethren, until a party which had followed them from Thessalonica stirred up a persecution against them. This determined Paul to go to Athens, whilst Timothy and Silas, as less obnoxious to the Jews, remained at Berea. It does not appear to have been the apostle's intention in the first instance in visiting Athens to preach the gospel there, at least until Timothy and Silas, to whom he had sent a message on his arrival, requiring them to join him, should have arrived; but as he waited for them, the sight of a city like that of Athens, entirely given to idolatry, so stirred and excited his spirit that he could no longer refrain; and accordingly, in the synagogues he disputed with the Jews, and in the market-place with such as he met. This led to his coming into contact with certain Stoic and Epicurean philosophers, by whom he was contemptuously invited to unfold his new doctrines, and describe the strange deities of which they supposed him to be the votary; and for this purpose he was taken to the Areopagus, where, with admirable tact, he exposed the follies of their idolatry, and commended to them the worship of the one living and true God, in the midst of a large assemblage of people, on some of whom a favourable impression was produced by his address.[5] Having been joined by Timothy,[6] and in all probability by Silas also,[7] he sent the former again to Macedonia, and either retaining the latter in his company, or despatching him to some other quarter, he himself passed over to Corinth.[8] On the occasion of this his first visit to that city, he supported himself by his labours as a tent-maker, in company with a pious couple named Aquila and Priscilla, who had taken refuge in Corinth after having been expelled from Rome by an edict of Claudius Cæsar against the Jews; and at the same time he availed himself of every opportunity of urging the gospel of Christ upon the acceptance both of Jews and Greeks. Here he was rejoined by Silas and Timothy, with whom he continued a year and a half in active exertion for the advancement of Christianity. By the persevering enmity of his former opponents the Jews, he was again compelled to leave Corinth, and betake himself, along with Aquila and Priscilla, to Ephesus. Here he abode at this time only a few days, having been commissioned by a divine revelation to go up to Jerusalem in time for the approaching feast of the passover. By some this, the apostle's *fourth* visit to Jerusalem after his conversion, is made to synchronize with that mentioned by himself in Gal. ii. 1. In this case we must suppose that his former friendship with Barnabas had been re-established, as he mentions him and Titus as his companions on this journey. This opinion, however, is opposed by many, who think that the visit mentioned in the Epistle to the Galatians happened at an earlier period, and was the apostle's *third* visit. After a brief residence in Jerusalem on this occasion, he returned to Antioch; and so finished his second great apostolic tour.[9]

At Antioch he abode for some time, and then commenced another extensive tour, accompanied, as is supposed, by Titus. Passing through Phrygia and Galatia, where he revisited the churches he had formerly planted, he arrived at Ephesus. This city stood in the same relation to the region of Hither Asia in which Jerusalem stood to Palestine, Antioch to Syria, Corinth to Achaia, and Rome to the West; and accordingly the apostle made it his head-quarters for three years, during which time he was occupied in making converts in the city, and in paying short visits to the surrounding places, and to Crete and other islands of the adjoining archipelago. With so much success were his labours attended in Ephesus, that the revenues of those who were interested in the support of the idolatrous worship of the tutelar goddess of the city, Diana, began to be affected; and at the instigation of one of these, by name Demetrius, a silversmith, who carried on an extensive manufacture of miniature representations of the famous temple of Diana at

Ephesus, a popular tumult was excited against the apostle, which was with difficulty appeased by the calm and sagacious conduct of the γραμματεύς, town-clerk or chamberlain, who, along with others of the chief men in the place, seems to have been friendly towards Paul. It was not on this occasion only that the safety of the apostle was endangered by popular turbulence at Ephesus; he seems to have been frequently in peril of his life in that city from the fury of the mob; and it is to this, in all probability, he alludes when he says, that "after the manner of men he had fought with wild beasts at Ephesus" (1 Cor. xv. 32); a statement which some have taken literally, but which the majority of interpreters agree to regard as figurative: "depugnavit ad bestias Ephesi, illos scilicet bestias Asiaticæ pressuræ de qua in secunda ad eosdem (sc. Corinthios, ch. i. 8.)," &c. (Tertullian, *De Resurrect. Carnis*, 48.) Whether therefore this tumult had any effect in quickening the apostle's determination to leave Ephesus may be doubted, especially as it is clear that he had come to that determination before it happened.[1] By divine direction, he had resolved to go to Macedonia; and accordingly, shortly after the tumult, he departed from Ephesus, and went by way of Troas to Philippi. There he seems to have remained a considerable while; for, during his residence at Philippi as his head-quarters, he preached the gospel in all the surrounding districts, even as far as to Illyricum, on the eastern shore of the Adriatic.[2] Leaving Philippi he paid a second visit to Corinth, where he abode three months, and then returned to Philippi, having been frustrated in his intention of proceeding through Syria to Jerusalem by the malice of the Jews. From Philippi he sailed for Troas, where he abode seven days; thence he journeyed on foot to Assos; and thence he proceeded by sea to Miletus, having visited several of the intermediate places. At Miletus he had an affecting interview with the elders of the church at Ephesus, to whom, in the prospect of seeing them no more, he gave a solemn and impressive charge, and bade them farewell. From Miletus he sailed for Syria, and, after visiting several intermediate ports, landed at Tyre, where he remained seven days. Thence he journeyed, by way of Ptolemais and Cæsarea, to Jerusalem, which he visited on this occasion for the *fifth* time since his conversion.[3]

At Jerusalem he recounted to the whole church the events connected with the progress of Christianity of which he had been witness, and, apparently to quiet the scruples of some Jewish converts, who thought he had too lax and incorrect a view of the obligation of the Mosaic ritual, he united himself, at the suggestion of the apostle James, to four persons who had taken upon them the vows of Nazarites, and, entering with them into the temple, signified to the priest that he would pay the cost of the sacrifices which were necessary to absolve them and him from the vow. Whatever effect this compliance had on the minds of his scrupulous brethren, it procured for him no mitigation of the hatred with which he was regarded by the unconverted Jews. On the contrary, so eager was their zeal against him, that, before his vow was accomplished, they seized him in the temple, and would have put him to death had not Lysias, commander of the Roman cohort in the citadel adjoining the temple, brought soldiers to his rescue. By his permission, and under his protection, Paul addressed to the infuriated mob an apology for himself, in which he set forth the main circumstances of his life from the beginning up to the period when he opened his commission to the Gentiles. At first he was listened to with attention, but as soon as he spoke of placing the Gentiles on a par with the Jews, they interrupted him with execrations, and shouted "away with such a fellow from the earth, for it is not fit that he should live."[4] The Roman commander, seeing these demonstrations of popular resentment, and being ignorant of what Paul had been saying, from the address having been uttered in the Hebrew tongue, imagined that he must be some execrable criminal, and gave orders that he should be brought into the fort, in order that he might by scourging compel him to confess his crime. From this indignity Paul saved himself by asserting his privileges as a Roman citizen, to bind or scourge whom was strictly forbidden by law. Next day the chief captain brought him before the Sanhedrim, for the purpose of hearing what it was that was urged against him; and here Paul again entered into a defence of his conduct, in the course of which he professed his attachment to the doctrine of a corporal resurrection, and thereby stirred up a fierce controversy between the two parties composing the Sanhedrim, the Pharisees and the Sadducees, the former of whom maintained, whilst the latter denied, this doctrine. So angry and vehement did this discussion become, that the chief captain, fearing for the safety of his prisoner, whom, as a Roman citizen, he was bound to protect, commanded his soldiers to go down and remove him from amongst the combatants into the fort. Upon the day following about forty of the Jews entered into a solemn engagement neither to eat nor drink until they had killed Paul, and for this purpose proposed to the chief priests to invite him to a conference, in the hope that they might have an opportunity of assaulting him on his way from the fort. This scheme was rendered abortive by intelligence of it having been conveyed to Lysias by Paul's sister's son, who, along with his mother, seems to have been an early convert to Christianity.[5] Matters assuming this desperate aspect, Lysias determined to bring the whole under the consideration of the procurator; and accordingly, placing Paul under the protection of a sufficient escort, he sent him to Cæsarea, with a letter to Felix, explaining the reasons of this step. After five days, Felix held a court, at which Paul and his accusers were brought together, and both parties heard at full length. The defence of the apostle was triumphant; but Felix, unwilling to offend the Jews, remanded him, under the pretence of obtaining farther information from Lysias. Some days afterwards, he summoned him again to his tribunal, in order that he and his wife Drusilla, who was a daughter of Herod Agrippa, might hear him "concerning the faith in Christ;" on which occasion, the apostle, with all that fearless zeal and faithfulness by which he was distinguished, expostulated so forcibly with the procurator in regard to those vices for which he was notorious, that Felix trembled, and hastily dismissed him from his presence. Shortly after this, Felix was removed from his office, and was succeeded by Porcius Festus, before whom the Jews again brought their charges against Paul. When both parties came to be heard, Paul perceived so evident a disposition in the new governor to favour the Jews, that he felt constrained to avail himself of the privilege which, as a Roman citizen, he possessed, of removing his cause from the province to the metropolis, by appealing to the emperor. This led to his being sent to Rome, but not before he had been again heard by Festus, attended by King Agrippa and his wife Bernice, by whom he was adjudged to have done nothing worthy of death or of bonds, so that he might have been set at liberty had he not appealed unto Cæsar. His voyage to Rome was long and disastrous.[6] After coasting along Syria as far as Sidon, they struck across to Myra, a port of Lysia, having passed under Cyprus; thence they sailed slowly towards Cnidus, and thence, in consequence of the wind being contrary,

to Crete, where they with difficulty put into a port on the southern side of that island, called the "The Fair Haven," near the city of Lasea. The season being now far advanced, Paul advised the centurion to proceed no farther; but the place not being suitable for wintering in, and the weather promising favourably, his advice was disregarded, and they again set sail, intending to reach Phœnice, a port in the same island, and there to winter. Scarcely, however, had they ventured to sea when the apostle's prediction was verified; for a boisterous wind arose and drove them at its mercy across the Mediterranean. In this state they continued for fourteen days, at the close of which they were shipwrecked on the coast of Malta, but without any loss of life. Here the apostle and his company remained for three months, during which time he was actively employed in instructing the inhabitants, and performing many miracles for their benefit. On the approach of spring, they availed themselves of a ship of Alexandria that had wintered in the island, and set sail for Syracuse, where they remained three days; thence they crossed to Rhegium; and thence along the coast to Puteoli, from which place he journeyed by land to the imperial city. Here he was delivered by the centurion, in whose charge he had come from Cæsarea, to the captain of the guard, who, with great lenity, permitted him to dwell in his own hired house, under the charge of a soldier.[1]

The sacred historian closes his narrative by informing us that Paul continued in this state of easy imprisonment for "two years, receiving all that came to him, preaching the kingdom of God, and teaching those things which concern the Lord Jesus Christ, with all confidence, no man forbidding him." Of the subsequent events of the apostle's life, consequently, we have much less direct and certain information; and from this has arisen much diversity of opinion on the subject. By many it is supposed that this his first imprisonment at Rome was his last, and that he perished in the persecution which Nero excited against the Christians by representing them as the agents in the burning of the city; whilst others contend that he was set at liberty before that event, and that he set out on another great missionary tour to the West, in the course of which he preached the gospel throughout Spain, and, according to some, in Britain also;[2] revisited Ephesus and other places in Lesser Asia, passed over to Crete, returned to Ephesus, passed through Troas into Macedonia, thence to Nicopolis in Epirus, Dalmatia in Illyricum, and back again to Asia, when he was apprehended and conveyed to Rome the second time, where he suffered martyrdom. By some who hold this latter opinion the order of places visited is completely reversed, and Paul is supposed to have commenced his tour in Asia, and ended it in Spain, whilst others omit Spain from the itinerary altogether. It would require a much larger space than this article can be permitted to occupy to enter into any examination of the arguments and evidence on both sides of this question. Suffice it to remark, that, whilst the whole subject is involved in much uncertainty, and whilst little more than probable conjecture can be furnished for the details of either hypothesis, the preponderance seems to be in favour of the latter. Our readers will probably be satisfied of this by a reference to what has been written on it by Greswell and Neander; the former of whom contends for it with all the zeal of an advocate, whilst the latter admits it with all the deliberation of a cautious and impartial judge.[3]

In the above sketch of the principal events of the apostle's life no attempt has been made to assign to each its proper date. This has resulted from the great perplexity in which this part of the subject is involved, and the consequent inexpediency of adopting any particular chronology without assigning the reasons on which it is founded; a course which would have extended this article greatly beyond its proper bounds. We have deemed it preferable, therefore, to present, in the first instance, the leading facts in the history of Paul in the order of their occurrence; and shall now furnish a table of the dates assigned to the more important of these in those systems of chronology which are most deserving of notice, leaving it with our readers to consult the works in which they are unfolded for the arguments by which they are respectively supported.

During the brief intervals of comparative ease which the apostle enjoyed amid his arduous and almost incessant exertions as a preacher of Christianity, he wrote several treatises, more or less elaborate, both of a doctrinal and a practical nature, in the shape of epistles to different churches. Of these, thirteen, avowedly of his composition, and one that is with great probability ascribed to him (the Epistle to the Hebrews),[10] have come down to us; and there is reason to believe that in these we have the whole of those compositions which, as an apostle of Jesus Christ, he gave to the church. It is supposed, indeed, by many distinguished biblical critics, that there is evidence, in the first of his extant epistles to the Corinthians, of his having written one to that church antecedently to either of these; but the basis of evidence on which this rests is at best very slender, and the support which it lends to what is raised on it very doubtful.[11] In what order these epistles were written, and what date is to be assigned to each, are points on which much discussion has been expended. The following lists present the results of the investigations of Greswell, Neander, and Alford:—

Neander regards the Epistle to the Hebrews as of uncertain authorship, but deems it probable that it was written about the period of the apostle's martyrdom, by "some apostolic man of the Pauline school."[2]

In perusing the history and the writings of St Paul, it is impossible not to be struck with the amazing energy of thought and action by which he was characterized. The conception of *power* is impressed upon the mind by every view of his history, and the study of every page of his writings. The ease with which he threw off the prejudices of Judaism, notwithstanding the deep hold which these had taken of his mind; the rapidity with which he expanded his thoughts to embrace the vast conceptions unfolded by the free offers and unbounded claims of Christianity, so different from the narrow sectarianism of his former religion; the accuracy with which he received into his mind, almost instantaneously, and in all their multiplicity, the mutual bearings and relations of the old economy and the new; the dauntless intrepidity with which, from the very commencement of his Christian profession, he entered into discussion with the advocates of Judaism, and vanquished them with their own weapons; the unflinching perseverance with which, in spite of danger, suffering, contumely, persecution from enemies, ingratitude and desertion from friends, he prosecuted his arduous and exhausting labours; the unwearying assiduity with which he watched over the churches of which he had the care, and the promptitude and accuracy with which he adopted and executed measures for their advantage, widely scattered and variously circumstanced though they were; the resistless force of his arguments, the persuasiveness of his appeals, the keenness of his irony; all conspire to show that he possessed in a high degree those capacities for command by which men are fitted to be the leaders and directors of their fellows in enterprises of importance to the interests of the race. But it was not by attributes of strength and power alone that the mind of Paul was characterized. The sternness of these was relieved and softened by others of a more amiable and gentle cast. A vein of tenderness and sensibility flowed through his soul, which, whilst it made him the more susceptible of suffering from ingratitude or persecution, rendered him at the same time gentle and compassionate to the feelings of others. With all his freedom from Jewish prejudices, he never lost his reverence for the country and institutions of his fathers; and with all his zeal for rectitude, and all his firmness in rebuking error, he never forgot what was due to the imperfections of his brethren, or deemed that truth could be made attractive if divorced from charity. Removed alike from the extremes of fanaticism on the one hand and apathy on the other, his whole life was a noble instance of the consecration, on sound and elevated principles, of the highest powers and the most indefatigable energies to a work in which he had no personal interest apart from that of his fellow-Christians, and from the honour which was to accrue from his exertions to that Master whom it was his high ambition to serve in life, and his animating expectation to join at death. Apart altogether from his character as an apostle of Christ, his labours in the cause of human amelioration entitle him to veneration as one of the greatest benefactors of the species; whilst in his peculiar capacity as one of the founders of the Christian church, and an inspired expositor of divine truth, he stands without a rival in his claims upon our gratitude and reverence. His history is a standing evidence of the truth of our religion; to his labours we are indebted mainly for the rapid extension of Christianity both in the East and in the West; and in his writings are contained those treasures of heavenly doctrine which it has been the chosen occupation of some of the greatest minds of subsequent ages to explore and to unfold. With these irresistible claims, the more his life, character, and writings are studied, the deeper will be the veneration in which he will be held, and the more sincere will be the gratitude of every pious mind to the Author of all good for having in so remarkable a manner supplied the church with a teacher so eminently qualified to advance its best interests, and establish, to the end of time, the faith, efficiency, and blessedness of its members.

(See, besides the works referred to in this article, the splendid work of Conybeare and Howson, *Life and Epistles of St Paul*, with maps, plates, &c., 2 vols. 4to, London, 1850–52, third edition, 2 vols. 8vo, 1858; Lewin's *Life and Epistles of St Paul*, 2 vols. 8vo, London, 1851; Schrader, *Der Apostel Paulus*, 5 vols., Leipz., 1829–36; Hemsen, *Der Ap. Paulus*, &c., Gott. 1850; Baur, *Paulus der Ap. Jesu Christi*, Stuttg. 1845.) (W. L. A.)

PAUL *of Samosata*, a celebrated heresiarch of the third century, was raised to the see of Antioch in 260 A.D. His conduct in this high position was marked by an unblushing attempt to secularize the duties and doctrines of religion. No sooner had he put on the episcopal robe than he started on an eager race for the pleasures and honours of this world. His pastoral authority was exercised to supply food for his avarice. His sacerdotal character was employed to screen his sensual indulgence. He trampled on the laws of the

[2] *Geschichte*, p. 433, Eng. trans., vol. i., p. 347; see also Delitzsch, *Commentar zum Br. an die Hebräer*, p. 701.

church by accepting the secular appointment of *ducenarius procurator.* He desecrated his holy office by cringing for the favour of Zenobia, the unprincipled queen of Palmyra. In his council-chamber he sat upon a lofty throne, and assumed the airs of a civil dignitary. In public he rode with all the pomp and retinue of a prince, and pretended to be constantly reading petitions and dictating mandates. In the pulpit he ranted like an actor, and paused at intervals to invite the plaudits of his congregation. Nor did the worldly-minded bishop hesitate to extend his sacrilegious innovations to the most sacred doctrines of the Christian creed. The Divine Being, he taught, was not a Trinity but a Unity. The Logos and the Holy Ghost were not persons of the Godhead, but were parts of the Deity, in the same manner as reason and spirit are parts of man. The Logos did not become incarnate in the person of Christ. It descended to earth, communicated its influence to the man Jesus, and then re-ascended to heaven. Jesus accordingly was not God. He only attained to an extraordinary degree of wisdom and virtue, which might entitle him, in a certain sense, to be called Divine. The flagrant practices, and especially the erroneous doctrines, of Paul of Samosata, at length awoke the opposition of the church. An inveterate conflict took place. His opponents held a council in 264 or 265, condemned his opinions, and allowed him to hold his see only on the faith of a promise that he would retract his heresy. But no sooner had the assembly dispersed than he broke his promise, and began to teach his old dogmas. His opponents returned to the charge, convoked another council in 269, and deposed him from his bishopric. But backed by the influence of Zenobia, he set this sentence at defiance, and retained his benefice in the face of the whole church for no less than three years. At length, however, in 272, the overthrow of his royal patroness by the Emperor Aurelian brought about his downfall. The settlement of the controversy was referred by the conqueror to the bishops of Italy; they sustained the decision of the council of 269; and Paul of Samosata, expelled from his see, disappeared into obscurity. There were a few sectaries, who called themselves, after the name of this heresiarch, *Paulianists.* They never became numerous, and in the fifth century they had fallen out of notice. (Neander's *Church History*, and Gibbon's *Decline and Fall of the Roman Empire.*)

PAUL *the Deacon* (also surnamed, after his father, *Warnefridus*), an eminent historian of the middle ages, was born about 740 at Cividale (*Forum Julii*), and completed his education at the court of Rachis, King of the Lombards. Although he commenced life as a humble deacon of the church at Aquileia, his learning and accomplishments soon set him upon a career of distinction. He became notary or secretary to Desiderius, the last Lombard monarch. His withdrawal into a cloister, on the overthrow of that prince in 774 by Charlemagne, did not consign his merits to oblivion. In no long time the victorious sovereign had summoned him to take up his abode at the court of France. He was there employed to teach Greek to the clergymen who had been selected to conduct the emperor's daughter Rotrude to Constantinople to be wedded by the son of the Empress Irene. Yet, in spite of these high honours, his last days were spent in obscurity in his native country. He died in the monastery of Monte Casino about 799. Paul the Deacon left behind him several works. His great work, since it is the only authority on its subject, is the *De Gestis Longobardorum.* It has often been printed, and it is contained in Muratori's *Rerum Italicarum Scriptores.* His other works are *Gesta Episcoporum Metensium, a Life of St Gregory the Great,* several Latin Hymns and Poems, and a collection of Homilies for all the Sundays and holidays in the year. He also appended to the History of Eutropius a continuation of the narrative down to the reign of Justinian, which has been continued in turn by another writer, and which is now known under the name of *Historia Miscella.*

PAUL I., *Pope*, succeeded Stephen II. in 757, and died in 767.

PAUL II., *Pope*, whose original name was Pietro Barbo, succeeded Pius II. in 1464. An attempt to raise a crusade against the Turks, a persecution of the Hussites, the excommunication of Podiebrad, King of Bohemia, and the dispersion of an academy which had been instituted for the study of classical antiquities, were the most notable acts of his pontificate. He died in 1471.

PAUL III., *Pope*, whose real name was Alessandro Farnese, succeeded Clement VII. in 1534. His rule was characterized by zeal and vigour. He excommunicated Henry VIII. of England, established the Inquisition at Naples, sanctioned the new order of the Jesuits, and condemned the system of doctrine called the "Interim," which the Emperor Charles V. had ordered to be drawn up. By him also was the general council convoked which had for its object the healing of the schisms in the church, and which continued to sit long after his death in 1549.

PAUL IV., *Pope*, who was originally called Gian Pietro Caraffa, was raised to the pontificate after Marcellus II. in 1555, at the age of eighty. He had became notable while archbishop of Theate or Chieti for his attempt to revive the sinking strength of Popery by introducing among the clergy the discipline and simplicity of primitive times. It now became his object to carry out the same plan on a much larger scale. Bent upon reforming not only the ecclesiastics but the Roman Catholic community at large, he obliged bishops to reside within their own dioceses, proscribed unprincipled publications, punished blasphemers, and even expelled his own nephews from Rome on account of their debaucheries. After a reign of four years, spent in this reformation, he died in 1559.

PAUL V., *Pope*, whose previous title was Camillo Borghese of Siena, succeeded Leo XI. in 1605, at the age of fifty-three. The most notable event in his pontificate was his dispute with the Venetian Senate. The occasion was the arraignment of two priests at Venice before the magistrate; and the subject was, whether in the Venetian territory religious edifices could be erected, property could be bequeathed to the church, and ecclesiastics could be accused of any civil crime, without being liable to the interference of the government. The pope asserted the affirmative: the Senate persisted in maintaining the negative. The Pope laid the territory under an interdict: the Senate expelled from their dominions all those who showed any respect to the interdict. Baronius and Bellarmine entered the field of literary controversy to support the see of Rome: the famous Father Paul appeared to defend the rights of Venice. His holiness at length employed the mediation of the King of France; but the senators did not give up the contest until they had triumphantly carried their point. Paul was more successful in his attempts to embellish Rome. He erected several spacious edifices, enlarged the Vatican and Quirinal palaces, constructed some of the most beautiful fountains, collected some of the finest specimens of painting and sculpture, and restored some of the richest pieces of the ancient architecture of the city. The death of Paul V. happened in 1621.

PAUL I., Czar of Russia, was the son of Peter III. and Catherine II., and was born in 1754. He succeeded to the throne in 1776, and was strangled in 1801. (See RUSSIA.)

PAUL, *Father.* See SARPI.

PAUL, ST, a town in the island of Réunion or Bourbon, stands on the W. coast, 19 miles S.W. of St Denis. It is shaded by acacias, and has a better harbour than that of St Denis. This was the earliest settlement made by the

French on the island. Pop. about 10,000; of the arrondissement, 16,262.

PAUL, *St*, an island in the Indian Ocean, S. Lat. 38. 44., E. Long. 77. 38., about 9 miles long, by 5 broad. It seems to be of volcanic origin; for it contains hot springs, and an old crater, now filled with water and abounding in fish. The island is covered with a stunted vegetation, and has good anchorage at the E. side.

PAUL DE LOANDA. See LOANDA.

PAULICIANS, THE, were an ancient religious sect which sprung up in Armenia in the seventh century. Their founder was one Constantine, an inhabitant of the village of Mananalis, in the neighbourhood of Samosata. This individual happening to receive a copy of the New Testament as a present, began to search the gospel record, and to extract from it a set of opinions peculiar to himself. He then preached his new doctrines with success in his native district, in Pontus, and in Galatia. A numerous band of followers gathered round him, who, forming themselves into a distinct sect, adopted a systematic creed. A certain part of their creed was merely a revival of some of the most flagrant errors of the early Christians. Thus they held, with the Gnostics, that the Old Testament was not canonical, and that the Creator of the world and the God of heaven were two distinct beings. They also held, with the Valentinians, that Christ's body was not a material body formed in the womb of the Virgin Mary, but an ethereal body brought along with him from heaven. Yet the greater part of their doctrine was a direct protest and a thorough-going polemic against the growing superstitions of the church. According to them, the holy cross was a piece of common or perhaps rotten wood; the wonder-working relics were a heap of offensive dust; the consecrated priesthood was a Jewish institution; the efficacious sacraments were mere symbols, the one denoting the baptism of the Spirit, and the other denoting the feeding upon the word of Christ; Mary, the mother of God, and the immaculate Virgin, was a frail mortal woman, and the parent of several mortal children; and even the great St Peter, the first bishop of Rome, was an unworthy apostle, whose two epistles ought to be expunged from the pages of the New Testament. This severely simple code of doctrine was accompanied by a severely simple rule of practice. It became the aim of the new sect to realize, even in the minutest accessories, the condition of the primitive church under St Paul. They listened to the precepts of the great apostle of the Gentiles as if he were speaking to them with a living voice, and they called themselves *Paulicians*, as if he were their founder and sole teacher. Their pastors were surnamed after the apostle's fellow-labourers, and their pastorates were named after the apostle's congregations. The sharp reproof which the Paulicians thus gave to both the creed and government of the church soon roused a vindictive persecution. For one hundred and fifty years each successive emperor, whether an image-worshipper or an iconoclast, deemed it either his duty or his interest to endeavour to suppress the harmless Armenian sect. Their teachers were martyred, their faith was assailed both by argument and force, and they were proscribed in all the provinces of the empire. The Empress Theodora brought the persecution to a climax, and provoked the persecuted to retaliate. Aiming at the total extirpation of the Paulicians, she beheaded, hung, drowned, and burned no less than one hundred thousand. The remnant, finding a refuge and a home in that part of Armenia which belonged to the Saracens, formed a league with the khalif for the purpose of inflicting retribution upon their common enemy. One of their number, Carbeas, a valiant soldier, was appointed to organize an expedition. At the head of an army composed of his fellow-sectaries and of Moslems, he invaded the provinces of the empire, and defeated the Emperor Paul under the walls of Samosata. Still more victorious was his successor Chrysocheir. Sweeping before him all opposition, he overran the whole of Asia, and pillaged Nice and Nicomedia, Ancyra and Ephesus. In vain did the Emperor Basil, the Macedonian, try both arms and negotiation. It was not until Chrysocheir had been surprised and slain that the invaders were driven back into their own district, and forced to defend their independence among the mountains. The Paulicians, however, were destined to be placed in a scene of more prosperous activity. About the middle of the eighth century, the Emperor Constantine Copronymus transplanted a large body of them from Armenia to Thrace; in the tenth century the Emperor John Zimisces increased the colony by a fresh number of emigrants; and in a short time they had obtained a firm footing in Philippopolis, and other cities in that part of the empire. As they grew in power and importance, they grew also in proselytizing zeal. Travelling westward as far as Germany and France, their missionaries made many converts, and fostered that spirit of opposition to the corruptions of the church which ultimately issued in the Reformation. (Gibbon's *Decline and Fall*, Mosheim's *Ecclesiastical History*, and Neander's *History of the Church.*)

PAULINUS, MEROPIUS PONTIUS ANICIUS, Bishop of Nola, was born in Bourdeaux, or its neighbourhood, about 353. The career of the future ecclesiastic began amid bright prospects of worldly preferment. His parents left him a munificent fortune; his opening taste for letters was fostered by the tuition of the poet Ausonius; he was raised to the rank of *consul suffectus;* and he won the hand of a wealthy and accomplished lady named Therasia. Yet the latter part of his life was characterized by an abandonment of all earthly cares and honours. In the course of a few years, his conversion to the truth of the gospel led him to distribute part of his possessions among the poor. Then a domestic affliction which he suffered while residing in Spain tended to increase this spirit of religious devotion. Becoming a presbyter in 393, he removed immediately to Campania to devote his remaining days to the duties of piety. He first spent nearly fifteen years in monk-like seclusion, practising acts of charity and self-mortification, and writing sacred poetry and theological treatises. At length, in 409, he entered upon the duties of the see of Nola, a post which he held till his death in 431. The works of Paulinus which have come down to us are fifty epistles, thirty-two poems, and a brief tract entitled *Passio S. Genesii Arelatensis*. They were first printed in an imperfect state by Badius, 8vo, Paris, 1516. The standard edition is that of Le Brun Desmarettes, 4to, Paris, 1685.

PAULUS ÆGINETA. See ÆGINETA.

PAULUS ÆMILIUS. See ÆMILIUS, *Paulus*.

PAULUS, *Heinrich Eberhard Gottlob*, a learned German divine, was born at Leonberg in Wurtemberg in 1761. The chief part of his attention during his educational course was directed to theology. He studied the oriental languages and the other branches of a divinity course at Tübingen and Gottingen, and then proceeding to England, completed his education at London and Oxford. On his return to his native country, Paulus entered upon a distinguished professorial and literary career. In 1789 he was appointed to the chair of oriental languages at Jena; in 1804 he became professor of theology at Würzburg, and in 1811 he began to teach exegesis and philosophy at the university of Heidelberg. At the same time, his pen was busily employed in theological literature. Among other works, he published *Philologisch-kritischer Commentar über das Neue Testament*, in 2 vols., Lubeck, 1800–5; *Das Leben Jesu*, in 2 vols., Heidelberg, 1828; and *Exegetisches Handbuch über die drei ersten Evangelien*, in 3 vols., Heidelberg, 1830–33. The death of Dr Paulus took place at Heidelberg in 1851.

PAULUS, *Julius*, one of the most eminent of the Roman

Pausanias.

jurists, flourished in the third century. The only facts of his biography that are known with any degree of certainty are, that Elagabalus banished him; that Alexander Severus recalled him, and made him *præfectus prætorio;* that he was a contemporary of Ulpian and Papinian; and that he was a most voluminous writer on laws. All that we know regarding his qualities as an author is derived from 2083 excerpts in the *Digest* of Justinian. He was concise in style, subtle in thought, and comprehensive in judgment.

PAUSANIAS, a celebrated Greek general, was the son of Cleombrotus, and nephew of Leonidas. The first important event in his life was the distinguished part which he played in repelling the second Persian invasion in 479 B.C. In that year the task of leading the Spartan contingent northward to the scene of war in Bœotia was entrusted to him. The other Peloponnesian allies joined him at the Isthmus of Corinth; the Athenian troops fell in at Eleusis; and the command of the assembled forces was then conferred upon him. Crossing Mount Cithæron at the head of 110,000 men, he confronted an army of 350,000 Persians on the banks of the River Asopus. After delaying several days, and changing his position twice, he came to a general engagement with the enemy at Platæa. Of all his forces, the Spartans fought most bravely; and of all the Spartans, he himself achieved the greatest feats of valour. The Persians were completely routed; their camp was stormed; and all their remaining troops, with the exception of a few thousands that escaped, were remorselessly butchered. This brilliant exploit secured for Pausanias another high post of honour. Not long afterwards, by the unanimous voice of the Greeks, he was placed in command of a fleet, and charged with the task of following up his former successes, and driving the Persians completely out of Europe. Sailing first to Cyprus, he liberated the cities in that island. Then steering his course to the Propontis, he finished his enterprise by capturing Byzantium. Here ended the distinguished career of Pausanias: the rest of his life was nothing else than a course of the most infatuated folly. Intoxicated with military success, his brain began to be filled with the most extravagant ideas. The Spartan mode of life, he thought, would no longer suit him: it was necessary to surround himself with the luxury and splendour of a Persian satrap. These foolish aspirations soon resulted in a deliberate attempt to sell his country to the Persians for a fortune and the hand of the daughter of Darius. His recall to Sparta to answer for his conduct did not make him abandon this treacherous design. He continued to correspond with the King of Persia until the interception of one of his letters brought his guilt to light and himself to punishment. Having taken refuge in the temple of Minerva, the ephori unroofed that edifice, built up the door, and allowed him to die of cold and hunger. His demise took place at some date between 471 and 466 B.C. The Life of Pausanias has been written by Cornelius Nepos.

PAUSANIAS, a celebrated Greek antiquary, has been supposed, from a passage in his own work, to have been a native of Lydia. The exact period of his birth and death is unknown, but he was employed on a part of his book in the reign of Hadrian, who died A.D. 139, and was writing the *Antiquities of Elis*, A.D. 174, in the fourteenth year of the reign of M. Aurelius (v. 1, 1). He must thus have been contemporary with Aulus Gellius, Ptolemy the geographer, Fronto the philosopher, Apuleius, and Lucian, though his pursuits were not likely to bring him in contact with any of them. The work which he has left is entitled Τῆς Ἑλλάδος Περιήγησις (*The Itinerary of Greece*). It is divided into ten books, containing an account of the antiquities in each of the provinces of Greece, in the following order:—Attica, Megaris, Corinthia, Sicyonia, Phliasia, Argolis, Laconica, Messenia, Elis, Achæa, Arcadia, Bœotia, and Phocis. He must have examined minutely every part of these provinces; and it is observed by Sir John Hobhouse, in his *Journey through Albania*, "that the exact conformity of present appearances with the minute descriptions of the *Itinerary* is no less surprising than satisfactory." Nothing escaped his observation. Mountains, rivers, fountains, temples, statues, and pictures are all described. He evidently took every means in his power to be accurate in his descriptions, as he constantly refers, as a corroboration of his statements, to inscriptions on ancient monuments and works of art, and to gifts dedicated in the temples of the gods. Poets and historians also furnished him with materials to illustrate the antiquities of the places he visited. He is accused, however, like the Latin historian Livy, of credulity, and of narrating many stories which have no pretension to credibility. But, aware that such an accusation might be brought against him, he states (vi. 3, 4) that he thought himself bound to give these traditions of the Greeks, though there was no reason why he should believe them. In his style he is thought to have imitated Herodotus, but by no means successfully.

Pausias ‖ Pauw.

The Greek text of Pausanias was first published at Venice in 1516 by Aldus; but this edition, which is in folio, is very incorrect, having been printed from a bad manuscript. That of Leipsic, 1696, in folio, published by Kuhn, is accompanied by the Latin translation of Amaseo, which had appeared separately at Rome in 4to, 1547. The edition of Clavier, Paris, 1814–1821, in 6 vols. 8vo, is accompanied by a new French translation. The latest edition is that of Schubart and Walz, in 3 vols. 8vo, Leipsic, 1838–40. It is only necessary further to indicate the Italian translation of Bonaccinoli, Mantua, 1597, in 4to; and that which appeared at Rome, 1792–1793, in 5 vols. 4to; the English translation of Taylor, London, 1793–1794, in 3 vols. 8vo; and the German translation of E. Wiedasch, in 4 vols. 8vo, Munich, 1826–29.

PAUSIAS, a distinguished Greek painter, was a native of Sicyon, and flourished in the fourth century B.C. His training was received under very favourable circumstances. He learned his first lessons in art from his father Brietes; he was then subjected to the thorough educational system of Pamphilus; and at the same time he was the fellow-disciple of such artists as Melanthius and Apelles. Accordingly his professional career was marked by surpassing excellence. He brought the art of painting in encaustic with the *cestrum* to an unprecedented pitch of perfection. By him was introduced the custom of decorating the walls and ceilings of private apartments with historical representations. He was also remarkable for his successful imitations of nature, and for his skill in foreshortening, as the portrait of "Glycera the Flower-Girl," and the picture of the "Ox about to be Sacrificed," sufficiently testified.

PAUW, CORNELIUS DE, sometimes called *Nicolas*, a moral philosopher and historian, born at Amsterdam in 1739. He is better known as the uncle of the revolutionist Anacharsis Clootz than by the ancestors from whom he was descended; they are, however, reported by his nephew to have distinguished themselves in the revolutions of Holland in the sixteenth century. It appears, from the same authority, that his name was Cornelius, and not Nicolas, but that he was not related to Cornelius de Pauw, the critic and the rival of Dorville; and that it was upon the marriage of his sister to Clootz's father that he obtained, through the interest of his brother-in-law, a Catholic canonicate at Xanten, in the territory of Cleves. He was afterwards appointed reader to Frederic, King of Prussia, perhaps as an advocate of the new doctrines and principles which that sovereign was disposed to patronize; but he is said to have declined the offer of the place of an academician of Berlin, and a bishopric at Breslau. His attacks on the Jesuits, whom he accused of gross misrepresentation and exaggeration in their historical and geographical memoirs, rendered

him unpopular with the Catholic clergy, though his learning and talents commanded a certain portion of their respect. He was simple in his manners, and somewhat negligent of his appearance. The close of his life was embittered by a tedious and painful disease; and he died on the 7th of July 1799.

His principal publications are—1. *Recherches sur les Américains*, Berlin, 1770 and 1772, in 8vo; a work intended to show the "degraded state of the savage Americans," and forming a contrast to the speculations of some contemporary writers of celebrity: 2. *Défense des Recherches*, Berlin, 1771, 8vo. 3. *Recherches sur les Egyptiens et les Chinois*, Berlin, 1774, in two vols. 8vo, Philosophical Dissertations on the Egyptians and Chinese, translated by Captain J. Thomson, London, 1795, in two vols. 8vo. The investigation was undertaken, he observes, to show "that no two nations ever resembled each other less than the Egyptians and the Chinese;" and it must be admitted that he has sufficiently established his proposition. There is, indeed, one argument that he has employed which appears to be founded on a mistake of the Greek historians of Egypt, who have asserted that the Egyptians had long been in the use of alphabetical characters; and the want of any alphabet amongst the Chinese is stated by M. de Pauw as affording a marked distinction from the Egyptians. There is, however, scarcely a shadow of resemblance in the particular hieroglyphical characters employed by the two nations, although the general system of beginning with a representation of a visible object, and departing more and more, by degrees, from the fidelity of the delineation, must necessarily have been common to both. But it so happens that, out of about seventy Egyptian characters, which are compared by the Jesuits and Dr Morton with the Chinese in the *Philosophical Transactions* for 1769, there are about twenty of which the sense has been ascertained with tolerable accuracy by Dr Young; and of these there is only one that happens to have been rightly determined by the comparison with the Chinese, excepting two or three which are obviously mere pictures, as the moon and a bow. There is also amongst the old Chinese characters a figure of a chain, which agrees remarkably in its form with the Egyptian hieroglyphic employed as a copulative conjunction; but there is a still more striking coincidence which M. Jomard has noticed between the Egyptian and Chinese characters for a thousand, both of which he derives from the seed-vessel of the lotus, as containing a multitude of seeds; and if the older Chinese characters be found to preserve this resemblance as perfectly as they ought to do, it must be confessed that the suspicion of a common origin will be much strengthened by the argument. Both the Egyptians and the Chinese were condemned, M. de Pauw observes, "to an eternal mediocrity;" and the weight of this observation is certainly not diminished by anything that has been inferred from the study of the hieroglyphics of the Rosetta stone and other monuments.

There are several papers of M. de Pauw on antiquarian subjects in the Memoirs of the Society of Cassel, and in particular one on the Temple of Juno Lacinia, vol. i., 1780. *Recherches sur les Grecs* were published at Berlin, 1787, in two vols. 8vo; *Philosophical Dissertations on the Greeks*, translated by Thomson, London, 1793, in two vols. 8vo. This work is principally devoted to the Athenians, amongst whom their boasted liberty is shown to have been confined to a very small number of citizens, who tyrannized over the rest of the inhabitants of their country. The Lacedæmonians, the Ætolians, the Thessalians, and the Arcadians, are separately discussed, but considered as comparatively contemptible; the Lacedæmonians in particular, and their successors, the Mainotes, are treated with great severity, as a worthless race of dishonourable vagabonds. The athletic education of the Athenians is, however, highly applauded, from a visionary theory of the importance of the physical perfection of the body to the operations of the mind. An edition of the author's three principal works appeared at Paris, in 7 volumes octavo, 1795. (See Dorsch, *Chardon-Larochette*, and Clootz, *Magaz. Encycl.* 1799; An. V., vol. ii., Widdigen, *Westph. Nationalk.* 1801, p. 215; *N. Allg. T. Bibl.* lxxiv., p. 77; Denina, *Prusse Littéraire*, iii., *N. Dict. Hist.* ix., 8vo, Par. 1804; Chalmers's *Biographical Dictionary*, xxiii., 8vo, Lond. 1815.) (T. Y.)

PAVIA, a frontier city of Austrian Italy, capital of a province of the same name, stands on the left bank of the Ticino, about 2 miles above its confluence with the Po, and 19 S.S.W. of Milan. On the opposite side of the river stands the suburb of Borgo Ticino, connected with Pavia by a handsome covered bridge of eight arches. The ancient walls which surround the city, being about 3 miles in circuit, inclose a much larger area than is required for the present population; and thus the numerous unoccupied spaces and uninhabited or ruinous dwellings give to the town a somewhat desolate look. It is, however, in general well built, and contains many venerable and splendid edifices. The chief thoroughfare is the Strada Nuova or Corso, extending from the bridge over the Ticino through the middle of the town, and terminating at the other end in a handsome gate. Along this street are erected the chief buildings, consisting of palaces, colleges, and churches, intermingled with theatres, shops, and coffee-houses. The smaller streets branch off from this at right angles; some leading to squares lined with stately but often neglected palaces. Among the churches the chief place is occupied by the cathedral, a large but unfinished building, begun in 1488. It is surmounted by a dome, and contains some good pictures, though these cannot be well seen, from the darkness of the interior. In a side chapel is the tomb of St Augustine, adorned with 290 figures in all, and remarkable both for the beauty of the design and the delicacy of the workmanship. The church of San Michele is the oldest in Pavia, and perhaps in all Italy, having been built probably in the beginning of the seventh century, though the precise date is unknown. It is in the style adopted by the Lombards, and is richly ornamented both in the interior and exterior. A specimen of architecture more approaching the English-Gothic than that of most Italian churches is to be found in Santa Maria del Carmine, which is beautifully built of brick, and has several fine windows and doors in the west front. Another church built of brick is that of San Francesco, a fine specimen of the Italian-Gothic style. The celebrated San Pietro in Cielo d'Oro, which is alluded to by Dante, is now partly in ruins and partly used as a storehouse. It contains the tomb of the famous Boethius. Several of the churches which formerly existed at Pavia have been demolished; and although before the reign of Joseph II. there were numerous large and wealthy convents, few of these now remain. The citadel of Pavia, which was completed in 1469, consisted, when entire, of a square court with towers at the corners, and surrounded by a double cloister; but one side of it was destroyed in 1527, and it was still further injured by the French in 1796; although it still presents a fine appearance. The treasures of art and literature that it formerly contained were carried to France by Louis XII. in 1499; and the place is now used for barracks. The university of Pavia gives to the town no small portion of its celebrity. It is of great antiquity, having been founded, it is said, by Charlemagne in 774, and restored in 1361 by Galeazzo Visconti, to whom it owes many of its privileges. It contains 13 colleges, 3 of which support gratuitously about 120 students; and there are faculties of law, medicine, philosophy, and mathematics. There were in the session 1853–4, 35 professors and 21 assistants; and the number of students was 1423. This university has long been celebrated for its medical and surgical teaching; and among the distinguished men who have been connected with it are Spallanzani and Volta, who were both professors of natural history here. Attached to the university are a library of 50,000 volumes, a museum, and a botanic garden. The buildings are extensive and regular, composing five quadrangles; and there are four square towers from 200 to 250 feet high. Similar towers once adorned Pavia in such numbers that the town was called *Civitas Turrigera*. Besides the university, there is an ecclesiastical seminary, several superior and elementary schools, an institute of fine arts, &c. The charitable establishments include an hospital for foundlings, two for orphans, a reformatory institution, and others. About 5 miles from Pavia, on the road to Milan, stands the Certosa, a splendid Carthusian convent, with a fine Gothic church. No manufactures of any consequence are carried on at Pavia; but the trade, though confined to the produce of the adjacent country, is in these articles considerable. Ticinum, the ancient city which

occupied the site of Pavia, was never of much consequence under the Romans; but the Lombard kings, who gave it the name of *Papia*, made it their capital. It is chiefly notable in history for the battle fought in its vicinity in 1525 between Francis I. of France and the army of Charles V., under the viceroy Lannoy, when the former was defeated and taken captive. Pop. 25,750.

The province of Pavia, which has an area of 400 square miles, is one of the most fertile parts of Lombardy, lying entirely in the plain of the Po, containing good pasture-land, and producing corn, wine, fruit, and hemp. Pop. (1853) 173,879.

PAVILION. See Glossary to ARCHITECTURE.

PAVLOGRAD, a town of Russia, capital of a circle of the same name, in the government of Yekaterinoslav, on the Voltscha, an affluent of the Dnieper, 30 miles E.N.E. of Yekaterinoslav. It contains two churches, a school, a benevolent institution, and several manufactories. Pop. (1851) 6929.

PAWNBROKER. See BROKER.

PAWTUCKET, a town of the United States of North America, partly in Rhode Island and partly in Massachusetts, stands on both sides of the River Pawtucket, 4 miles N.N.E. of Providence. It contains eight or nine churches, a masonic temple, and a public hall; the last two being very fine buildings. The town is chiefly remarkable for its manufactories; and these are supplied with abundant water-power by the river, which, within a short distance, falls about 50 feet. The first cloth factory moved by water in America was established here in 1790. Machinery and cotton fabrics are now the goods principally produced, though boots and shoes, carriages, and cabinet-ware are also made. The trade is considerable; and during the year 1852, 141 vessels arrived here, with a tonnage of 12,798. Pawtucket is connected by railway with Boston and Providence. Pop. (1853) about 10,000.

PAXO. See IONIAN ISLANDS.

PAZ DE AYACUCHO, LA, a town of Bolivia, capital of a department of the same name, stands on both sides of the deep ravine Quebrada-de-Choquehapu, 12,195 feet above the level of the sea, but 620 below that of Lake Titicaca, from which it is not far distant; S. Lat. 16. 30., W. Long. 68. 30. The streets are irregular, and some of them very steep; but there is a very handsome public square. Nine elegant bridges cross the stream, which flows through the ravine, and which forms one of the sources of the Amazon. Of the 15 churches, the chief is the cathedral, a large and noble edifice. There is also a university, a school of law, college of sciences, school of mechanical arts, and other seminaries. A large proportion of the inhabitants are Indians, who live in mud huts, and retain their primitive language and mode of life. La Paz is the principal commercial town in Bolivia, European goods being brought hither from Peru, and exchanged for gold, bark, and other commodities of the country. It was founded in 1548, under the name of *Nuestra Señora de la Paz*, and soon became a place of much importance. Since 1605 it has been the seat of a bishopric. In 1825 the name was changed to that which it now bears, in honour of the victory of Ayacucho, which secured the freedom of the country. Pop. 42,000.

PAZ, *La*, a department of Bolivia, bounded on the N. and E. by that of Beni, S. by those of Cochobamba and Oruro, and W. by Peru, has an extent of 36,418 square miles. It comprises those valleys of the Cordilleras through which the head streams of the Rio Beni flow. Pop. 346,000.

PEA, the English name applied to the seed of several leguminous plants, but chiefly to those of the cultivated pea (*Pisum sativum*, Linn.), an annual plant, and a native of the south of Europe. It has been cultivated as a culinary vegetable from a very early period; but from the slight mention made of it by Pliny, it does not appear to have been valued so much by the Romans as by the Greeks, who prized it very highly, and cultivated it extensively. It is not known when the pea was first cultivated in Britain; but long after its introduction it was rare, and in the time of Elizabeth it was imported from Holland, probably in a ripe state. Dr Fuller, writing of peas at that time, said they were "fit dainties for ladies, they came so far and cost so dear." Either as a horticultural or as an agricultural product, the pea is a vegetable of great importance. The seeds in a green state are regarded as one of our most esteemed vegetables when boiled; and when ripe, are much used in forming a favourite and nutritious soup, acceptable to all classes. Those produced in fields are allowed to ripen, and are of great value in feeding swine; the haulm is also cut up with other kinds of fodder, and is much relished by cattle. The garden pea is often cultivated in fields near large towns, where the demand for it, as a green vegetable, is considerable; it is, however, a very distinct variety from the field pea.

Few vegetables have rewarded the care of the cultivator more than the garden pea, of which there are now at least fifty varieties, which have been produced by a careful hybridization of the following well-marked botanical varieties of the plant:—1. Var. α. *saccharatum*, having round distant seeds, with coriaceous pods, called Sugar Pea, and in France *petits-pois* and *pois-sucres*.—2. Var. β. *macrocarpum*, a strong-growing large kind, with flattened falcate-formed pods containing large and distant seeds. The most remarkable peculiarity of this variety is, that the legumes are destitute of the hard membrane with which others are lined, in consequence of which this sort is cooked and eaten in the pod. The French call it *pois-goulons*, *pois-sans-parchemin*, and *pois-mange-tout*.—3. Var. γ. *umbellatum*. The stipules in varieties α. and β. are entire and rounded, but in the present one they are quadrifid and acute. The peduncles are surmounted with a rather compact cluster of flowers; hence it is called in English Crown-Pea, and in French *pois-à-bouquet*. It has been suggested that this is a true species.—4. Var. δ. *quadratum*. The seeds are of moderate size, and so closely packed in the legume that they become square when full grown. The French call it *pois-carré*.—5. Var. ε. *humile*. A dwarf, weak-growing kind, with round seeds closely placed in the legume. The varieties raised from these are valued according to their hardiness and early bearing, the size and sweetness of the seeds, their abundant bearing, &c. They may be arranged in four groups: those which have *yellow* seeds round when ripe, and those which have square wrinkled seeds; those which have *green* seeds round when ripe, and those which have square and wrinkled ones. All the varieties of the true garden pea have white flowers; but the field pea has red and purple flowers, and the seed when ripe is of a yellowish-brown mottled colour. The pea, as an agricultural crop, is in favourable situations a very useful one, and is so soon off the ground that a crop of turnips can usually be realized after it. In England this crop is usually found most abundant in the midland counties. Large quantities of peas are also imported in a ripe state. These are of the round and yellow kind, and are used chiefly for making soup. The quantity imported in 1857 was, in quarters,—from Denmark, 21,763; Prussia, 8265; Hanse Towns, 4870; Holland, 2630; Morocco, 9000; United States, 6200; British North America, 36,000; other parts, 2000;—the total value of which was nearly L.200,000. (T. C. A.)

PEACE RIVER, in British North America, rises to the west of the eastern chain of the Rocky Mountains, within 300 yards of Frazer River, which takes an opposite course, and flows through the mountains and the plains beyond, first eastward, and then N.E. Near the foot of Lake Athabasca it joins the Slave River, which issues from this lake,

and flows northward to the Great Slave Lake. Its whole length is estimated at 800 miles; and it is navigable for boats even above the Rocky Mountains. The Peace River gives its name to an extensive division of the Hudson's Bay Company's territory.

PEARCE, ZACHARY, D.D., Bishop of Rochester, was the son of a distiller in High Holborn, and was born in 1690. He received his education at Westminster school, where he was elected a king's scholar. At the age of twenty he entered Trinity College, Cambridge; and during the first years of his residence there, he occasionally amused himself with lighter compositions, some of which are inserted in the *Guardian* and *Spectator*. In 1716 he published his edition of Cicero *De Oratore*, and dedicated it to Lord Chief-Justice Parker, afterwards Earl of Macclesfield, a prudent step, which laid the foundation of his future fortune. In 1717 Pearce was ordained, and during the following year became chaplain to Lord Parker. In 1719 he was installed in the rectory of Stappleford Abbots in Essex; in 1720, in that of St Bartholomew; and in 1723, in that of St Martin's-in-the-Fields, London. Besides Lord Parker, Pearce could now reckon amongst his patrons or friends Mr Pulteney (afterwards Earl of Bath), Archbishop Potter, Lord Hardwicke, Sir Isaac Newton, and many other eminent personages. In 1724 the degree of Doctor of Divinity was conferred on him by Archbishop Wake. The same year he dedicated to his patron the Earl of Macclesfield his edition of Longinus *On the Sublime*, with a new Latin version and notes. The deanery of Winchester having become vacant, Dr Pearce was appointed to it in 1739; in the year 1744 he was elected prolocutor of the Lower House of Convocation for the province of Canterbury; and on the 12th of February 1748 he was made bishop of Bangor. Upon the death of Bishop Wilcocks, he was promoted to the see of Rochester and deanery of Westminster in 1756. In the year 1763 his lordship, being then in the seventy-third year of his age, and finding himself less fit for the business of his station as bishop and dean, expressed a desire to resign. His Majesty was inclined to favour his wishes, but the bishops disliked the proposal. He obtained leave, however, to resign the deanery in 1768, and in 1774 he died.

In addition to the works already alluded to, this learned prelate wrote numerous sermons and tracts, published on various occasions. Four volumes of his posthumous sermons were given to the world by his chaplain, John Derby, in 1778. He likewise wrote *Miracles of Jesus Vindicated*, 1727 and 1728; *A Review of the Text of Milton*, 1733, containing an able refutation of Bentley's chimerical emendations; *Two Letters against Dr Middleton*, occasioned by the doctor's letter to Waterland, on the publication of his treatise, entitled *Scripture Vindicated*, 1752. But the work which above all others displays the solid learning and ripe judgment of the author is *A Commentary, with Notes, on the Four Evangelists and the Acts of the Apostles*, &c., 2 vols. 4to, Lond. 1777. This work contains also an autobiography of the author, together with additions from the pen of Dr Samuel Johnson.

PEARL is produced by a secretion peculiar to the Mollusca, and chiefly employed in the formation of their shells. (See MOLLUSCA.) In a few species pearl attains an economic importance, and gives rise to considerable branches of industry. Its normal development is as a slimy excretion from the exterior surface of the mantle, which being applied to the inner surface of the shell increases its thickness by the deposition of successive layers. It is abnormally developed for the purpose of covering grains of sand or other foreign bodies, which, by getting accidentally between the delicate mantle and the shell, would, but for this protection, cause irritation and disease to the former. Man takes advantage of both circumstances. By the former process he is supplied with mother-of-pearl, and by the latter with the precious pearls used in jewellery. These are generally spherical in form, and unconnected with the shell of the animal. Linnæus showed that by perforating a living pearl oyster, and introducing a grain of sand, a nucleus is formed for the development of a pearl.

Precious pearls have been ranked as gems from a very early period; and then, as well as now, the finest both in size and colour were obtained from the Indian Ocean, and are produced by the bivalve *Meleagrina margaritifera*, Lam. The famous wager between Cleopatra and Marc Antony gives us an insight into the value of pearls. At that time the two pearl ear-drops which the luxurious queen proposed to dissolve in vinegar, and serve up at the promised costly repast, were valued at 10,000,000 of sesterces, or about L.76,000. The pearl belonging to A. J. B. Hope, Esq., M.P., the largest known in modern times, and far too large to be used as an ear-drop, is not worth a fourth of that sum. It weighs 1800 grains, or 3 ounces, and has a circumference of 4½ inches, and a length of 2 inches. The most usual dimensions of good oriental pearls is from the size of a pea to about three times that size. When much below the size of a pea they are called *seed pearls*. These seed pearls, as well as the larger kinds, were in great request in the time of Pliny; for he says, "And now at the present day the poorer classes are even affecting them, as people are in the habit of saying that a pearl worn by a woman in public is as good as a lictor walking before her" (the size bespeaking the importance of the person). "Nay, even more than this, they put them on their feet, and that not merely on the laces of their sandals, but all over the shoes; it is not enough to wear pearls, but they must tread upon them, and walk with them under foot as well." (Bohn's edit.) Small pearls are also yielded by other bivalves, as the common oyster, mussel, and more particularly by the pearl-mussel (*Unio margaritiferus*), which was also known to the Romans; for Pliny says, "It is a well-ascertained fact that in Britannia pearls are found, though small and of a bad colour; for the deified Julius Cæsar wished it to be distinctly understood that the breast-plate which he presented to Venus Genetrix, in her temple, was made of British pearls." (Bohn's edit.) They are also mentioned by Tacitus in his Life of Agricola as indigenous products of Britain; he describes them "as not very orient, but pale and wan." (See MOLLUSCA.) Strangely enough, these seed pearls, the collection of which was eagerly pursued as a branch of profitable industry by the ancient Britons, is still followed by their descendants in the principality. The traveller who sojourns in the neighbourhood of Conway is sure to be solicited to purchase British pearls, which may be obtained from 5s. to 10s. per ounce. They are of little value except as curiosities.

The finest oriental pearls are obtained from Ceylon and the Persian Gulf, the seed pearls chiefly from Kurrachee, on the Bombay coast, where they are washed ashore, and are collected by coolies, under contractors, who pay 40,000 rupees (L.4000) to the Julpore government for the privilege. The seed pearls are chiefly used by the natives of India and Persia, who attribute important medicinal virtues to them. Pearls of good size and colour are sometimes collected in the West Indies and on the coast of South America. Imports were received from the following places in 1856:—Egypt, value L.32,570; St Thomas, L.20,744; New Granada, L.1000; British West India Islands, L.500; other parts, L.348.

The same animal (*Meleagrina margaritifera*) which yields the precious pearl produces also the mother-of-pearl shells of commerce. They are often very large, nearly circular in form, and very slightly convex externally. Specimens are occasionally seen 12 inches in diameter. Generally the *nacre*, or pearly material, constitutes the chief

part of the shell, only a thin, worn, dark-coloured crust forming the outside coating or epidermis. They are principally collected on the shores of Madagascar, Ceylon, Manilla, Panama, &c. There are three principal kinds:—1*st*. The *silver-lipped*. These have a yellowish pearly lustre, generally very clear and bright. The largest shells also occur amongst them. Their value ranges from L.80 to L.130 per ton. They are imported chiefly from Manilla and China. 2*d*. *Blue-edged* or *black-lipped*, from South America or other places, worth from L.30 to L.40 per ton. 3*d*. The *Panama* or *bullock-shell*, a small kind from Panama, worth from L.18 to L.21 per ton. The quantity imported in 1856, of all sorts, was 2102 tons, of the value of L.76,544. They are used for a variety of purposes—for the manufacture of buttons, for knife-handles, for inlaying, &c. Great numbers are sent to the Holy Land, where the monks carve upon them religious pictures, often of great artistic merit, which are sold to visitors as souvenirs of their visits to the holy places. Many tons are annually consumed in this way, and in making rosary beads and other small articles. The beautiful opalescence of these shells appears to depend upon "minute undulations of the layers, which has been successfully imitated upon steel buttons." (Woodward, *Manual of Mollusca*.) Other shells are occasionally imported and used by the button-maker and inlayer in consequence of the brilliancy of their nacreous layers, as *Turbo marmoratus*, Linn., from China, and the beautiful *Haliotis gigas* from the Indian Seas. (T. C. A.)

Pearl Fisheries. Owing to the circumstance of the pearl-oyster being found congregated, like the common oyster, in great abundance in certain localities, regular fisheries are established, some of which have furnished pearls for many centuries. Ceylon, still the most famous of the pearl fisheries, was celebrated for the same valuable product in the time of Pliny, when that island was called *Tabrobane*. The same writer also mentions the island of Stoidis as one of the places in the Persian Gulf especially celebrated for its pearl fishery. The same method of procuring pearls was practised in the time of the Romans as in modern times,—viz., by diving and dredging, but especially by the former. As the exertion demanded from divers is exceedingly violent, they are generally said to be unhealthy and short-lived. The best fishery ground is at a depth of 6 or 8 fathoms water, where the divers remain under water from 50 to 80 seconds, but rarely longer. Percival, in his *Ceylon*, tells of a diver who came from Anjango in 1797, and who could absolutely remain under water for full six minutes. They seldom use any precaution to prevent the water from injuring them, and make forty or fifty descents daily, bringing 100 oysters in their bag on each occasion. The fishing season seldom lasts above a month, beginning about the 5th of March. The pearl fisheries of the present day are situated on the west coast of Ceylon, especially in the Bay of Condatchy, the coast of Coromandel, the Bahrein Islands in the Persian Gulf, the coast of Algiers, the Sooloo Islands, the Gulf of Panamá, and the island of Margarita. The finest oriental pearls are obtained from Ceylon and the Coromandel coast. These fisheries are in the hands of the government, by whom they are regulated and farmed out. The beds are annually surveyed, and their condition reported to the government. They are divided into four equal portions, one only of which is allowed to be worked in each year. By this means a three years' rest is insured after each fishing, thus affording the growing meleagrinas, which are free and active in their young state, an opportunity of settling down on the bed, from which the weight of their full-grown shell prevents them from moving in the adult state. As perhaps no fishery of any kind produces such a vast amount of wealth, and gives so much scope for speculation in so short a space of time, the shores of the Bay of Condatchy in the months of February, March, and April present a very animated spectacle. Here are found Indians and Jews—merchants, boatmen, divers; conjurors to chain the sharks, so dreaded by the divers; Brahmins and Roman Catholic priests, many of the Malealie divers being Roman Catholics. The merchants and jewellers are busy and excited with their trade, often speculating upon the contents of their favourite boats before their arrival. The fleet of boats leaves the shore at ten o'clock at night upon the firing of a signal-gun, and returns at noon the following day. As soon as they appear, the gun is again fired, and the flags are hoisted; the shore is quickly crowded with anxious faces, and a perfect Babel is witnessed when the boats touch the strand, inquiries in twenty or more languages being shouted out by the eager crowd as to the result of the cruise. The cargo of each boat is quickly landed and taken possession of by its owners, who immediately commence opening the shells and searching for the pearls. These pass into other hands as soon as found; and the excitement is greater than ever, caused by the hawkers and others engaged in the purchase and preparation of the gems for other markets, as they are all drilled and cleaned on the spot. (See Percival's *Ceylon*.) It is almost impossible to tell the exact value of the produce of pearls, as there is no arrangement for the purpose, and the contracts taken by the government (about L.45,000 per annum) afford no criterion, as they barely pay the working expenses.

The pearl fisheries of the Bahrein Islands, belonging to Persia, are said to yield annually from L.200,000 to L.240,000 sterling. A considerable fishery exists at Kurrachee, on the Bombay coast, which is let by the Indian government to contractors for about 40,000 rupees (L.4000) annually. The pearls are, however, of little value, being very small. They are called *seed pearls*, and are chiefly used in medicine by vytians and hakims (Hindu and Mohammedan doctors). According to Dr Ainslie, the powder of pearls is supposed to have the virtue of strengthening weak eyes, and to have considerable efficacy in palpitations, nervous tremors, hemorrhage, and other affections. Hence the fishery for seed pearls is kept up with vigour; but they are obtained from the shells thrown on the coast by the surf, and not by diving.

The South American pearl fisheries are carried on with great activity; but the quality of the pearls is not equal to those of the East. In 1587, 697 lb. weight of pearls were imported from Colombo and Margarita into Spain. Philip II. obtained a pearl from Margarita in 1574 which weighed 250 carats, and was worth 150,000 dollars (L.31,875). In 1824 Messrs Rundell, Bridge, and Rundell obtained the exclusive right of using these fisheries for ten years.

Notwithstanding the great value of the pearls yielded by the various fisheries, it is probable that the shells of the animals now yield a far more profitable return than the jewels. In 1856 the total value of pearls imported into the United Kingdom was L.56,162; whereas the imports of 2102 tons of the shells were valued at L.76,544. (T. C. A.)

Pearl Islands, a small group of islands belonging to New Granada, in the Bay of Panamá, 60 miles S.E. of the town of Panamá. They consist of S. Miguel, S. José, Pedro Gonzales, and other smaller ones; and derive their name from the pearls that are obtained there.

PEARSON, Edward, D.D., a learned divine of the English Church, was descended from the famous Dr John Pearson, Bishop of Chester, and was born at Norwich on the 7th November, 1756. He was educated at Sidney College, Cambridge, of which he afterwards became fellow and tutor. No sooner had he been appointed rector of Rempstone in Nottinghamshire in 1796, than he began a career of great professional activity. His zeal was manifested with marked effect in the inculcation of practical re-

Pearson. ligion. He preached numerous sermons on special occasions, edited prayer-books and catechisms, and wrote tracts and discourses for the special enlightenment of the lower classes. Nor were his faculties less willingly exerted against schismatics. He published *Three Plain Reasons against Separating from the Established Church, Three Plain Reasons for Infant Baptism,* and *An Admonition against Lay-Preaching.* But it was for his bold attack on supposed heresies among the Anglican hierarchy that Dr Pearson was chiefly famous. In 1800 and 1801 successively he attacked the theoretical and the practical part of Paley's *Moral and Political Philosophy;* and in 1802 he published *Remarks on the Controversy between the Arminian and the Calvinistic Ministers of the Church of England.* He assailed the Calvinism of the evangelical party in the person of Overton of York in 1802, and of Simeon of Cambridge in 1810. His death happened in 1811, three years after he had been elected master of Sidney College, Cambridge. (See *A brief Memoir of the Life, Writings, and Correspondence of the Rev. Ed. Pearson, D.D.*, by W. P. Hunt, 1845, to which is appended a complete list of the author's writings.)

Pearson, *John,* D.D., a learned English bishop, was born at Great Snoring in the county of Norfolk, on the 28th of February 1613. After his education at Eton and Cambridge, he entered into holy orders in 1639, and was the same year collated to the prebendary of Netherhaven, in the church of Sarum. In 1640 he was appointed chaplain to the Lord-Keeper Finch; and was presented to the living of Thorington in Suffolk during the same year. In 1650 he was made preacher of St Clement's, Eastcheap, in London. In 1657 he and Peter Gunning had a dispute with two Roman Catholics upon the subject of schism, a very unfair account of which was printed at Paris by one of the disputants, named Tyrwhitt, in 1658. In 1659 he published at London his celebrated *Exposition of the Creed,* dedicated to his parishioners of St Clement's, Eastcheap, to whom the substance of that excellent work had been preached several years before, and by whom he had been desired to make it public. The same year he likewise published the *Golden Remains of the ever-memorable Mr John Hales of Eton,* to which he prefixed a preface containing a character of that eminent man, with whom he had been acquainted for many years, drawn up with great elegance and force. Pearson had also a principal share in the editing of the *Critici Sacri,* first published in 1660. Soon after the Restoration he was presented by Juxon, then bishop of London, to the rectory of St Christopher's in that city; created doctor of divinity at Cambridge, in pursuance of the king's letters mandatory; installed prebendary of Ely, archdeacon of Surrey, and made master of Jesus College in Cambridge, all before the end of the year 1668. In 1661 he was appointed Margaret professor of divinity in that university; and on the first day of the ensuing year he was nominated one of the commissioners for the review of the Liturgy in the conference held at the Savoy. On the 14th of April 1662 he was admitted master of Trinity College in Cambridge; and in August resigned his rectory of St Christopher's and his prebend of Sarum. In 1667 he was admitted a fellow of the Royal Society. In 1672 he published at Cambridge *Vindiciæ Epistolarum S. Ignatii,* in 4to, in answer to Daillé; to which is subjoined *Isaaci Vossii Epistolæ Duæ adversus Davidem Blondellum.* Upon the death of the celebrated Dr Wilkins, Pearson was appointed his successor in the see of Chester, to which he was consecrated on the 9th of February 1672–1673. In 1682 his *Annales Cyprianici* were published at Oxford, with Fell's edition of that father's works. Pearson was disabled from all public service by ill health a considerable time before his death, which happened at Chester on the 16th of July 1686. Pearson's last work, the *Two Dissertations on the Succession and Times of the First Bishops of Rome,* formed the principal part of his *Opera Posthuma,* edited by Henry Dodwell in 1688. (See a Memoir of Bishop Pearson, prefixed to the edition of his *Minor Theological Works,* by Edward Churton, 2 vols., Oxford, 1844.)

Peat. PEAT is formed by the partial decay of vegetable matter, especially of various species of mosses. It exists in most parts of Northern Europe. The vast peat-bogs of Ireland, amounting probably to not less than three million English acres, of an average depth of 19¼ feet, represent an amount of raw material which is now being looked to by economists as a source of wealth, instead of being the exponent of sterility. Peat may be made valuable in various ways; *first,* as a source of fuel. At present, however, while coal is abundant and cheap, peat will probably be unable to compete with it. The time may come when the country will look with eagerness to Ireland for the supply of fuel, which is a necessary element in our greatness and prosperity; and that time may not be so far distant as is generally supposed, when we consider the fact that our present annual consumption of coal is about seventy million tons. In the year 1856 the quantity of coal raised in the United Kingdom amounted to 66,645,450 tons.

In the article Fuel, some details are given respecting peat as a source of heat, and we may here give a few additional particulars. The heating power depending on the per-centage of pure carbon found in the peat, the source of the supply becomes a matter of importance, seeing how very variable is the value of the peat in different localities. Dr Sullivan states that "the variation in the quality of peat is so great, that no statements as to its economical value can be relied on which do not give the per-centage of ash, the per-centage of water, and the specific gravity. The variation in the latter amounts to 0·3 to 1·1 for air-dried turf from the great centre bogs."[1] Mr W. Longmaid states that "the best samples of peat contained, when dried, about 70 to 75 per cent. of carbon; but other samples were contaminated with earthy matters to the extent of from 5 to 10 per cent.; the average impurities may be taken at from 4 to 5 per cent., and we have found some samples of peat charcoal yielding 94 per cent. of fuel."[2]

Messrs Gwynne & Co. have taken out several patents for the preparation of peat fuel. In one of their patent processes, the peat, as dug from the bog, is deprived of much of its moisture by being placed in a large centrifugal machine, after which it is ground to powder, and passed through a series of cylinders revolving in a heated chamber, where the remaining moisture is got rid of, and the powder raised to the proper temperature for compression; it is carried from the last cylinder by two pockets to the compressing tables, and having passed through them, the solidified peat is ready for use. In another process the moisture is got rid of by passing the peat between cylinders containing, at equal distances along their outer surfaces, projections equal to the thickness of the slabs of peat. The drying of these is completed in the hot chamber, or they are at once converted into charcoal. It is found that when the peat powder has been dried at a temperature of about 180°, and in that state allowed to enter the hopper of the compressing engine, the tarry properties of the turf are just sufficiently developed to form a good cementing compound, and the brick of compressed turf, when cold, forms a dense and very pure fuel. Dr Letheby, who has examined this patent solidified peat fuel, reports that its specific gravity is as high as 1·140, its structure hard and dense, and the stowage weight of one cubic foot of the fuel is 71·24 lb., that of

[1] Private communication to Professor Miller of King's College, London.

[2] Lecture before the Society of Arts, January 1855.

Newcastle coal being about 49·69 lb. 100 parts of the peat contain 9 of hygroscopic moisture; they yield 55 parts of volatile matter, much of which is condensable, and 36 of charcoal. The charcoal contains 3·8 of ash. 7000 grains of the peat were distilled in an iron retort, and the volatile products were conducted through a red-hot iron tube, under the impression that the paraffine, &c., of the tar would be converted into a gaseous hydrocarbon of high illuminating power. The results were 2520 grains of peat coke, or charcoal; 1320 of ammoniacal liquor; 360 of thick tar; and 2800 of combustible gas: the gas occupied 625 cubic feet, and when burnt at the rate of 5 cubic feet an hour, from an Argand burner, with 15 holes, and a 7-inch chimney, it yielded a light equal to that of 7 sperm candles, each burning at the rate of 120 grains per hour. According to this analysis, 100 parts of the peat furnish

Porous charcoal	36·00
Ammoniacal liquor	18 86
Thick tar, containing paraffine	5·14
Gas having the illuminating power of 7 candles	40 00
	100·00

Although the illuminating power of the gas is not very high, the quantity is considerable (a ton of the material furnishing as much as 14,000 cubic feet), and as much of the gas and paraffine had been rendered gaseous by their passage through a red-hot tube, they might probably be further decomposed and converted into gases of high illuminating power. When the gas had been purified, by passing it through an alkaline mixture, it was found to be free from sulphur, in which respect it has an advantage over coalgas.

In using the solidified peat as fuel, no opaque smoke is evolved, no sulphurous acid is set free, the heat is quickly raised and quickly diffused, the ashes do not form clinkers, and the peat does not contain any metallic sulphuret, or other substance that is likely to produce spontaneous combustion.

Messrs Gwynne propose to apply their prepared peat to the reduction of ores by combining it with the proper fluxes; and having formed the furnace charge of fuel, flux, and ore, by powerful compression into globular masses, these are piled up in the furnace, the spaces between them admitting a sufficient quantity of air for maintaining the combustion. Peat charcoal is of great value in the manufacture of iron, on account of its being almost free from sulphur. Its deodorizing and purifying qualities are also high.

According to Mallet (whose experiments on Irish peat have been generally confirmed by those of Brix on Prussian peat), the heating power of good dry turf, as compared with that of the coke of bituminous coal of good quality, is as 1 : 7·61, and air-dried peat will convert about its own weight of water, at 60°, into steam at 212°. In Bavaria peat is dried artificially to a large extent as fuel, for the use of locomotive engines; and at Kœnigsbrunn it has for many years been employed in the puddling furnaces for the conversion of cast into wrought iron.

Peat has thus been shown to be valuable, *first*, as a fuel; *secondly*, as a source of illuminating gas; and we have now to refer to it in the *third* place, as a source of various products obtained from its destructive distillation. The ultimate elements of peat are essentially the same as those of wood and of coal, namely,—carbon, nitrogen, hydrogen, and oxygen. If, therefore, peat be distilled in close vessels, the resulting products will resemble those of a similar operation on wood or coal. In the Great Exhibition of 1851, Mr Oxland exhibited the products obtained by the destructive distillation of Dartmoor peat in cast iron retorts; but as the expense of the process was too great for its adoption in Ireland, it occurred to Mr Reece to make use of a blast-furnace similar to that employed in the smelting of iron ore, with an additional contrivance for collecting the products of combustion. By this means peat has been made to yield ammonia, acetic acid, pyroxylic spirit, tar, naphtha, oils, and paraffine, all useful products in the arts. The ammonia which is fixed and separated by the addition of sulphuric acid, forming sulphate of ammonia, is employed in the preparation of carbonate and hydrochlorate of ammonia, of caustic ammonia, and in the production of manures and composts. The acetic acid, which is fixed and separated by the addition of lime, forming acetate of lime, is a useful source of acetic acid, and of various acetates consumed by the calico-printer. Pyroxylic spirit, or wood alcohol, may be separated by distillation, and is used in vapour-lamps, and in the preparation of varnishes. Naphtha is also used in making varnishes, and for dissolving caoutchouc. The heavy and more fixed oils may be used as cheap lamp oils, and for making lamp-black, or, mixed with other unctuous substances, they are well fitted for the lubrication of machinery. Paraffine, either alone or mixed with sperm or stearine, forms excellent candles. Paraffine is a crystalline substance of the specific gravity 0·870. It is destitute of taste, colour, and odour; at 112° it is a transparent oily liquid, and at a higher temperature it boils and distils without change; its vapour burns with a white sootless flame. It resists the action of acids, alkalies, chlorine, and potassium, and cannot be united by fusion with camphor, naphthaline, benzole, or pitch. It is on account of this inertness as a chemical agent, or want of affinity, that it derives its name from *parum affinis*. It unites, however, with stearine, cetine, bees'-wax, and colophony, and dissolves in oil of turpentine and in naphtha. Mr Bagot states, that 100 tons of peat yield 10,000 gallons of liquor containing ammonia, carbonic acid, acetic, and pyroligneous acids, pyroxylic spirit, and 1000 gallons of tar, containing paraffine, heavy oil and light oil. The inflammable gas is economically used by being passed under the steam-boiler. The 1000 gallons of liquor yield one ton of sulphate of ammonia, sufficient acetic acid to produce 13 cwt. of grey acetate of lime, and 52 gallons of pyroxylic spirit. The tar yields 300 lb. of paraffine, 200 gallons of naphtha, or light hydrocarbonaceous oil, and 100 gallons of heavy oils.

The above results are, however, much too favourable for constant practice. Dr Sullivan has ascertained that none of the paraffines of commerce are definite bodies; but mixtures of different isomeric hydrocarbons. In relation to the distillation of peat, he says:—"Now that a ready market exists, I have no doubt that 3 lb. of paraffine per ton of good dry peat could be separated, especially by keeping over the summer oils until winter; in cold winters, perhaps even more. Gas enough can be produced to work the factory (heating stills, &c.), but it has now been satisfactorily determined that the larger the supply of gas, the less will be the yield of tar, and *vice versâ*. The yield of tar when the temperature has been carefully attended to, has fully reached the anticipated quantity; but neither the ammonia nor the wood spirit has. The real source of profit, therefore, is the tar. Tar about 3·5 per cent., paraffine 0·13 per cent." (*Private communication.*)

Thus it will be seen that whether we regard peat as a fuel, as a source of charcoal, of gas, or of the various other products named, it cannot, except for the sake of the tar, be worked at a profit, until the manufactures connected with it can compete in price with similar products already in the market. It must, however, be remembered, with respect to peat as a source of fuel, that while coal would cost the Irish labourer three times as much as it costs the Northumbrian cottager; the peat is at hand, and can be had almost for nothing. (C. T.)

PECK, Francis, a laborious and learned antiquary, was born at Stamford, in Lincolnshire, on the 4th of May 1692, and educated at Cambridge, where he took the degrees of

Bachelor and Master of Arts. After several unsuccessful flights in poetical composition, he, in 1727, published in folio his *Academia tertia Anglicana, or the Antiquarian Annals of Stamford, in Lincoln, Rutland, and Northampton Shires*, inscribed to John, Duke of Rutland. Peck had before this time obtained the rectory of Godeby, near Melton, in Leicestershire, the only preferment he ever enjoyed. In 1732 he published the first volume of *Desiderata Curiosa*, or a collection of various scarce and curious pieces relating chiefly to matters of English history. This volume was dedicated to Lord William Manners, and was followed, in 1735, by a second volume, dedicated to Dr Reynolds, Bishop of Lincoln. In the year 1735 Peck printed a complete catalogue of all the discourses written for and against Popery in the time of King James II., containing in the whole an account of 457 books and pamphlets, with references after each title, and an alphabetical list of the writers on each side. After editing Dr Hammond's *Letters* in 1739, he next year produced *Memoirs of the Life and Actions of Oliver Cromwell, as delivered in Three Panegyrics of Noll, written in Latin, and supposed to have been composed by John Milton, Latin Secretary to Cromwell;* also, *New Memoirs of the Life and Poetical Works of Mr John Milton, with an Examination of Milton's Style, and Explanatory and Critical Notes on different passages in Milton and Shakspeare*, together with sundry poetical effusions, "in imitation of Milton." At his death in 1743, this singularly industrious author is said to have had no fewer than nine different works in contemplation.

PECKHAM, a large suburban hamlet of London, in the county of Surrey, 4 miles S.S.E. of the metropolis, consists of a long line of handsome edifices. Among its numerous churches belonging to different sects there are some handsome buildings. It has several schools, a lunatic asylum, and a large silk factory. Pop. (1851) 19,444.

PEDAL (*pedale* in Italian) is a musical term of various meanings. For example, *pedal* means one of the largest pipes, or one of the foot-keys, of an organ; or the foot-piece attached to a piano-forte, a harp, or the like, and by which, in the former, the intensity of the sound is modified, and, in the latter, the chromatic changes of intonation are produced. It also signifies a particular sort of passage in the course of a piece of music, where the harmony moves upon a sustained sound, which is either the dominant or the tonic of the key. (See MUSIC.) (G. F. G.)

PEDESTAL. See Glossary to ARCHITECTURE.

PEDIMENT. See Glossary to ARCHITECTURE.

PEDOMETER (πούς, *a foot*, and μέτρον, *a measure*), an ingenious instrument in the form of a watch, designed to ascertain the space of ground over which one has travelled. Of the various contrivances of this sort, that of Payne, watchmaker in Bond Street, London, is decidedly the most convenient. The instrument is so arranged that when the body of the traveller is raised by the spring of his foot in walking, or by the motion of his horse, a small lever is jerked downwards which communicates its motion to the wheel-work of the machine. The distance passed over is pointed out in miles on a dial-plate, by means of an index. In adapting the pedometer to carriage travelling, the ordinary horizontal position of the lever becomes perpendicular, and the instrument is allowed to oscillate like a pendulum.

PEEBLESSHIRE, or TWEEDDALE, a county in Scotland, situated between 55. 24. and 55. 50. N. Lat., and between 2. 45. and 3. 23. W. Long. It is bounded on the N. by Mid-Lothian or Edinburghshire, E. by Selkirkshire, S. by Dumfriesshire, and W. by Lanarkshire. Its greatest extent from N. to S. is about 30 miles, and its greatest breadth from E. to W. about 22; the area being 354 square miles, or 226,488 English acres, of which only about an eighth part is fit for cultivation. It is divided into sixteen parishes, twelve of which form the presbytery of Peebles, and four belong to that of Biggar; but all are under the synod of Lothian and Tweeddale.

The surface of this county is hilly, and towards the S. mountainous, the principal high grounds in that quarter being Hartfell, 2635, Broadlaw, 2740, and Dollarlaw, 2790 feet above the level of the sea. None of the southern counties of Scotland have so great a general elevation as Peeblesshire; yet, with few exceptions, the hills are covered with green herbage, and afford good sheep pasture. On the banks of its streams are many pleasant and fertile spots, and the large extent of young plantation has added greatly to the amenity of the district, which was formerly very bare of timber. The soil of the cultivated land, lying chiefly on the sides of the lower hills and the banks of the streams, is for the most part a light loam, with clay, moss, and moor on the high grounds. Graywacke, both massive and slaty, is the prevailing rock in the S. and middle of the county, and there are many good quarries in the neighbourhood of Peebles, though in other places it is too laminated in its structure to be good for building. In the northern parts old red sandstone is the principal formation. Coal, limestone, and freestone abound in the parishes of Linton and Newlands, on the N. side of the county, and are profitably worked in the former of these parishes; in the latter ironstone is also found. At Stobo, slate of a good quality is quarried, and sold with advantage to the proprietor. In the parish of Traquair there is also a slate quarry, but the increased use of Welsh slates has affected the demand. The river Tweed, from which this district is often called Tweeddale, rises from a well of the same name, in the parish of Tweedsmuir, in the south-western extremity of the county, about 1500 feet above the level of the sea, and, flowing first N.E. and then E., dividing the county into two nearly equal parts, it passes into Selkirkshire at Gatehope Burn, after a winding course of about 36 miles. The Annan and the Clyde have their source in the same hill. Of the other streams, here called *waters*, the most considerable are Biggar, Lyne, Peebles or Eddlestone, Leithen, Manner, and Quair, which fall into the Tweed; and the North and South Esks, which pursue their course into Mid-Lothian. The lakes or lochs are St Mary's, Waterloch, and Slipperfield. These, as well as the rivulets, abound in the common fresh-water fish, and most of the streams are occasionally visited by a few salmon; but these are not found in such numbers during the fishing season, even in the Tweed, within the bounds of this county, as to afford a fishery that will pay rent.

The climate of Peeblesshire, owing to its elevation, is sharp and bracing, but as regards its other characteristics is similar to the rest of the south of Scotland.

As this is almost exclusively a pastoral country, the farms are in general large, most of them being from 1000 to 4000 acres. On the arable land they are small, the greater number being below 100 acres. These are in general held on leases for nineteen years, as in other parts of Scotland. The average rental in 1843 was above 6s. an acre. This is chiefly derived from live stock, especially sheep, of which there may be about 120,000. These were formerly of the black-faced heath variety, sometimes called Tweeddale sheep, from the name of the county, or Linton sheep, from the name of a village on the northern side of the district, where great fairs are held for the sale of them; but for a number of years the Cheviot breed, which bears a much more valuable fleece, has been established on many of the lower hills, and the majority of those now fed in the county are of this variety. The crops are the same as in other parts of Scotland, excepting that wheat is cultivated only upon a very small scale. A variety of oats, called the *red oat*, and sometimes the *Magbiehill oat*, from its being first cultivated here on that estate, is very well adapted to

Peebles.

high and exposed situations, both because it ripens earlier than the common kind, and is less liable to be beaten out by wind, whilst on good land it is found to be highly productive.

Peeblesshire contains numerous noblemen's and gentlemen's seats, some of which are remarkable for antiquity or beauty. The principal of these are:—Nidpath Castle, belonging to the Earl of Wemyss; Traquair House, to the Earl of Traquair; Darnhall, to Lord Elibank; King's-Meadows, to Sir Adam Hay, Bart.; Stobo Castle, to Sir Graham-Graham Montgomery, Bart., and others. The old valued rental was L.4328; the new valuation for 1858–9 was L.78,361. The number of proprietors is 193. The principal remains of antiquity are rude monumental stones at Stobo and Gatehope; Roman camps at Lyne, Linton, and Manner; and British chesters, or hill forts, in various places. Drochil Castle in the parish of Newlands, which, however, was never finished, and Nidpath Castle in the parish of Peebles, are the only two which are in tolerable preservation; but vestiges of ancient castles or towers abound in the whole valley of the Tweed. The remains of the Castle of Tinnes or Thanes are 6 feet in thickness, and the mortar is as hard as the stone.

The county is traversed by numerous roads, which are kept in good repair. The principal are those which lead from Peebles to Edinburgh, Glasgow, Dumfries, and Melrose. The town of Peebles is also connected by railway with Edinburgh. The principal towns or villages in Peeblesshire are, Peebles, Linton, Eddlestone, Skirling, Broughton, and Innerleithen. At this last place there is a mineral well, which annually attracts numerous visitors to the village; and both Peebles and Innerleithen have become favourite resorts for summer visitors. Several woollen manufactories are in operation in Innerleithen.

According to the census of 1851, Peeblesshire contained in all 31 places of worship, of which 13 belonged to the Established Church, 8 to the Free Church, 5 to the United Presbyterians, 2 to the Episcopalians, and 1 to the Independents. There were at the same time 28 day-schools, with 1526 scholars; and 19 Sunday schools, with 879 scholars. The county, including the town of Peebles, returns one member to the House of Commons. The parliamentary constituency in 1857 was 389. Pop. (1811) 9935; (1821) 10,046; (1831) 10,578; (1841) 10,499; (1851) 10,738.

PEEBLES, the county town of Peeblesshire, stands on the left bank of the river Tweed, here crossed by a bridge of five arches, 22 miles S. of Edinburgh, with which it is connected by railway. The Eddleston Water, which here joins the Tweed, flows through the town, dividing it into an old and a new portion. The latter contains many substantial buildings; and since the completion of the railway numerous elegant villas have been built for summer residences. Peebles possesses a parish church, a Free church, and places of worship for United Presbyterians, Episcopalians, and Roman Catholics; also a town-house, jail, grammar-school, and scientific institute. The Chambers' Institution, the gift of William Chambers, Esq., to his native place, is a picturesque suite of buildings, containing reading-room, gallery of art, library, museum, and public hall. Peebles is not noted for any particular trade or manufacture. It was long a hunting residence of the Scottish kings, and Alexander III. founded here in 1260 a monastery for Red Friars, some remains of which still exist. In 1357 it sent two members to Parliament. It was destroyed by the English in 1545, but was afterwards rebuilt and surrounded by walls, which continued standing till 1707. The burgh is governed by a provost, 2 bailies, a treasurer, dean of guild, and 7 councillors: municipal constituency, 97. The annual revenue of the burgh property is about L.300. The annual value of real property in the burgh in 1858–9 was L.4592. Pop. (1851) 1982; inhabited houses, 310.

Peel.

PEEL, THE RIGHT HONOURABLE SIR ROBERT, *Bart.*, twice prime minister, and for many years the leading statesman of England, was born on the 5th of February 1788 in a cottage near Chamber Hall, the seat of his family, in the neighbourhood of Bury—Chamber Hall itself being at the time under repair. He was a scion of that new aristocracy of wealth which sprang from the rapid progress of mechanical discovery and manufactures in the latter part of the eighteenth century. His ancestors were Yorkshire yeomen in the district of Craven, whence they migrated to Blackburn in Lancashire. His grandfather, Robert Peel, first of Peelfold, and afterwards of Brookside, near Blackburn, was a calico-printer, who, appreciating the discovery of his townsman Hargreaves, took to cotton-spinning with the spinning-jenny, and grew a wealthy man. His father Robert Peel, third son of the last named, carried on the same business at Bury, with still greater success, in partnership with Mr Yates, whose daughter Ellen he married; made a princely fortune; became the owner of Drayton Manor, and member of Parliament for the neighbouring borough of Tamworth; was a trusted and honoured, as well as ardent, supporter of Mr Pitt; contributed magnificently towards the support of that leader's war policy; was rewarded with a baronetcy; and founded a rich and powerful house, on whose arms he emblazoned, and in whose motto he commemorated, the prosperous industry from which it sprang. The great minister was always proud of the self-won honours of his family; and as a public man his heart strongly felt the bias of his birth. He was sent, however, to be educated with the sons of the old nobility and gentry at Harrow, one of the most aristocratic of English schools, and at Christ Church, then the most aristocratic of English colleges. At Harrow, according to the accounts of his contemporaries, he was a steady, industrious boy; the best scholar in the school; fonder of solitary walks than of the games of his companions, but ready to help those who were duller than himself; and not unpopular among his fellows. At Christ Church, where he entered as a gentleman commoner, he studied hard, and was the first who, under the new examination statutes, took a first class both in classics and in mathematics. His examination in the Schools for his B.A. degree in Michaelmas term 1808 was an academical ovation in presence of a numerous audience, who came to hear the first man of the day; and a relation who was at Oxford at the time has recorded that the triumph, like both the triumphs and reverses of after-life, was calmly borne. From his classical studies Sir Robert derived not only the classical, though somewhat pompous character of his speeches, and the Latin quotations with which they were often happily interspersed, but something of his lofty ideal of political ambition. Nor did he ever cease to love these pursuits of his youth; and in 1837, when elected lord rector of Glasgow university, he, in his inaugural speech, passed a glowing eulogy on classical education. To his mathematical training, which was then not common among public men, he no doubt owed in part his method, his clearness, his great power of grasping steadily and working out difficult and complicated questions. His speeches show that, in addition to his academical knowledge, he was well versed in English literature, in history, and in the principles of law. In after-life he had a taste for art, though none for music, and took an interest in science, though he had no scientific education. While reading hard, he did not neglect to develop his tall and vigorous frame, and fortify his strong constitution, by manly and gentlemanlike exercises; and though he lost his life partly through his bad riding, he was always a good shot and an untiring walker after game. Sprung from the most religious class of English society, he grew up and remained through life a religious man; and from that source drew deep conscientiousness and tranquillity under all difficulties and in all fortunes.

His Oxford education confirmed him in the principles of the Protestant Church of England. His practical mind remained satisfied with the doctrines of his youth; and he never showed that he had studied the great religious controversies, or that he understood the great religious movements of his day.

In 1809, being then in his twenty-second year, he was brought into Parliament for the close borough of Cashel, which he afterwards exchanged for Chippenham; and commenced his parliamentary career under the eye of his father, then member for Tamworth, who fondly saw in him the future leader of the Tory party. Pitt, Fox, and Burke were gone. Sheridan shone with an expiring ray. But in that House of Commons sat Wilberforce, Windham, Tierney, Grattan, Perceval, Castlereagh, Plunkett, Romilly, Mackintosh, Burdett, Whitbread, Horner, Brougham, Parnell, Huskisson, and above all, George Canning. Lord Palmerston entered the House at the same time, and Lord John Russell a few years afterwards. Among these men young Peel had to rise. And he rose, not by splendid eloquence, by profound political philosophy, or by great originality of thought, but by the closest attention to all his parliamentary duties, by a study of all the business of Parliament, which made him at length perfect master of all public questions and of all public interests, and by a style of speaking which, owing its force not to high flights of oratory, but to knowledge of the subject in hand, clearness of exposition, close reasoning, and tact in dealing with a parliamentary audience, backed by the character and position of the speaker, improved with his information, practice, station, and experience, till it gave him an unrivalled command over the House of Commons. The Tory party was then all-powerful at home; while abroad Europe was at the feet of Napoleon. But Napoleon's fortune was about to turn; and with the close of the struggle against revolutionary France, political progress in England was soon to resume the march which that struggle had arrested. Young Peel's lot, however, was cast, through his father, with the Tory party. In his maiden speech, seconding the Address, he defended the Walcheren expedition, which he again defended soon afterwards against the report of Lord Porchester's committee. It is said that even then Lord Liverpool discerned in him a dangerous tendency to think for himself, and told his father that he must be put at once into the harness of office. Into the harness of office, at all events, he was put, being made Under-Secretary for the Colonies by Mr Perceval in 1811. In 1812, being then only in his twenty-fifth year, he was transferred by Lord Liverpool to the more important but unhappy post of Secretary for Ireland. There he was engaged till 1817 in maintaining, by insurrection acts and other repressive measures, English and Protestant ascendancy over a country heaving with discontent, teeming with conspiracy, and ever ready to burst into rebellion. A middle course between Irish parties was impossible. Mr Peel became by the necessity of his situation "Orange Peel," and plied the established engines of coercion and patronage with a vigorous hand. At the same time, it was his regular task to combat Grattan, Plunkett, Canning, and the other movers and advocates of Catholic emancipation in the House of Commons. He, however, always spoke on this question with a coolness of temper wonderful in hot youth, with the utmost courtesy towards his opponents, and with warm expressions of sympathy and even of admiration for the Irish people. Nor was the ground he took against the Catholics that of religious principle never to be abandoned, but that of political expediency, which political necessity might overcome. He also, thus early, did his best to advocate and promote secular education in Ireland as a means of reconciling sects and raising the character of the people. He materially improved the conduct of ordinary business in his office, and gave great satisfaction to merchants and others with whom he had to deal. But his greatest service to Ireland as secretary was the institution of the regular Irish constabulary, nicknamed after him "Peelers," for the protection of life and property in a country where neither life nor property were secure. His moderation of tone did not save him from the violent abuse of O'Connell, whom he, young, hot-tempered (though his temper was generally under perfect control), and sensitive on the point of honour, was ill-advised enough to challenge,—an affair which covered them both with ridicule at the time, and left O'Connell his bitter enemy for life. In 1817 he obtained the highest parliamentary distinction of the Tory party, by being elected member for the university of Oxford—an honour for which he was chosen in preference to Canning on account of his hostility to Catholic emancipation, Lord Eldon lending him his best support. In the following year he resigned the Irish secretaryship, of the odious work of which he had long been very weary, and remained out of office till 1822. But he still supported government with official zeal, even in the question of the "Peterloo massacre." In the affair of Queen Caroline, however, he stood somewhat aloof, not approving the cause of government, and sensitive to popular opinion; and when Canning retired on account of this affair, he declined Lord Liverpool's invitation to take the vacant place in the cabinet. During this break in his tenure of office he had some time for reflection, which there was enough in the aspect of the political world to move. But early office had done its work. It had given him excellent business habits, great knowledge, and a high position; but it had made him somewhat stiff, somewhat punctilious, somewhat too cold and reserved to win the hearts of those whose confidence he might command, and somewhat over anxious for formal justifications when he had better have left the essential patriotism and probity of his conduct to the judgment of men of honour and the heart of the people. At the same time he was no pedant in business; in corresponding on political subjects he loved to throw off official forms, and communicate his views with the freedom of private correspondence; and where his confidence was given, it was given without reserve.

At this period he was made chairman of the Bullion Committee, on the death of Mr Horner. He was chosen for this important office by Mr Huskisson, Mr Ricardo, and their fellow Economists, who saw in him a mind open to conviction, though he owed hereditary allegiance to Pitt's financial policy, and had actually voted with his Pittite father for a resolution of Lord Liverpool's government denying the existence of any depreciation in the paper currency. The choice proved judicious. Mr Peel was converted to the currency doctrines of the Economists, and proclaimed his conversion in a great speech on the 24th of May 1819, in which he moved and carried four resolutions embodying the recommendations of the Bullion Committee in favour of a return to cash payments. His financial reputation was made, and his currency doctrines were fixed, from that hour; and his co-operation with the Economists on this occasion gave a liberal turn to his commercial principles. At the same time, he somewhat diverged from his party, and particularly from his father, who remained faithful to Mr Pitt's depreciated paper, and between whom and his schismatic son a solemn and touching passage occurred in the debate. The author of the Cash Payments Act had often to defend his policy; and he generally defended it firmly, though he may be said to have given way in being a party to the Small Notes Respite Act of 1822. The act has been often said to have been hard on the debtor interest, including the nation as debtor, because it required debts to be paid in cash which had been contracted in depreciated paper; and Mr Peel, as heir to a great fundholder, was even charged with being biassed by his personal inter-

ests. But it is answered that the Bank Restriction Acts, under which the depreciated paper had circulated, themselves contained a provision for a return to cash payments six months after peace.

In 1820 Mr Peel married Julia, daughter of General Sir John Floyd, who bore him five sons and two daughters. One of his sons, Frederick, he lived to see a rising man in the House of Commons; while another, William, the sailor, has run a bright course in another sphere, and found a glorious grave. The writers who have most severely censured Sir Robert Peel as a public man, have suspended their censures to dwell on the virtues of his private and domestic life. It was virtuous and it was happy, drawing happiness from the purest source. He was not only a most loving husband and father, but a true and warm-hearted friend. In Whitehall Gardens or at Drayton Manor he gladly opened his mind, wearied with the cares of state, to the enjoyments of a circle in which it was his pleasure and his pride to gather some of the most distinguished intellects of the day. He loved free and cheerful talk, in which he showed a keen sense of the ridiculous, and a dry, sarcastic humour; which often broke out also in his speeches in the House of Commons. He loved the conversation of men of science; he loved art, and was a great collector of pictures; he loved farming and agricultural improvements; he loved promoting useful works, and the advancement of knowledge; he loved making his friends, dependents, tenants, and neighbours happy. And, cold as he was in public, even to those whom he desired to win, yet in his gay and social hour, few men whose minds were so laden could be gayer or more social than Sir Robert Peel.

In 1822 Mr Peel consented to strengthen the enfeebled ministry of Lord Liverpool by becoming Home Secretary; and in that capacity he had again to undertake the office of coercing the growing discontent of Ireland, of which he remained the real administrator, and had again to lead in the House of Commons the opposition to the rising cause of Catholic emancipation. In 1825, being beaten on the Catholic question in the House of Commons, he wished to resign office; but Lord Liverpool pleaded that his resignation would break up the government. He found a happier and more congenial task in reforming and humanizing the criminal law, especially those parts of it which relate to offences against property and offences punishable by death. The five acts in which Mr Peel accomplished this great work, the first step towards a complete and civilized code, as well as the great speech of March 9, 1826, in which he opened the subject to the House, will form one of the most solid and enduring monuments of his fame. Criminal law reform was the reform of Romilly and Mackintosh, from the hands of the latter of whom Peel received it. But the masterly bills in which it was embodied were the bills of Peel,—not himself a creative genius, but, like the founder of his house, a profound appreciator of other men's creations, and unrivalled in the power of giving them practical and complete effect. This great measure, beyond the sphere of party, was probably also another step in the emancipation of Mr Peel's mind.

In 1827 the Liverpool Ministry was broken up by the fatal illness of its chief; and under the new premier, George Canning, Mr Peel, like the Duke of Wellington and other high Tory members of Lord Liverpool's cabinet, refused to serve. Mr Canning and Mr Peel were rivals; but we need not interpret as mere personal rivalry, that which was certainly in part at least a real difference of connection and opinion. Canning took a Liberal line, and was supported by many of the Whigs; the seceders were Tories, and it is difficult to see how their position in Canning's cabinet could have been otherwise than a false one. Separation led to public coolness and occasional approaches to bitterness on both sides in debate. But there seems no ground for saying that Mr Peel "hunted Canning to death." Canning himself said to a friend, who reported it to Sir Robert Peel, that "Peel was the only man who had behaved decently towards him." Their private intimacy remained uninterrupted to the end; and Canning's son afterwards entered public life under the auspices of Peel. The charge of having urged Catholic emancipation on Lord Liverpool in 1825, and opposed Mr Canning for being a friend to it in 1827, made against Sir Robert Peel in the fierce corn-law debates of 1846, has been withdrawn by those who made it.

In January 1828, after Canning's death, the Duke of Wellington formed a Tory government, destined to be the last, in which Mr Peel was Home Secretary, leader of the House of Commons, and probably virtual prime minister. Of this cabinet, Tory as it was, the impracticable Lord Eldon was not a member, and Mr Huskisson and four more of Canning's friends were. Its policy was to endeavour to stave off the growing demand for organic change by administrative reform, and by lightening the burdens of the people. The civil list was retrenched with an unsparing hand, and the public expenditure was reduced lower than it had been since the Revolutionary war, or has been since. Mr Peel also introduced into London the improved system of police which he had previously introduced with so much success into Ireland. But the tide ran too strong to be thus headed. First the government were compelled, after a defeat in the House of Commons, to acquiesce in the repeal of the Test and Corporation Acts, Mr Peel bringing over their High Church supporters, as far as he could, through Dr Lloyd, Bishop of Oxford, his tutor at Christ Church, and now his beloved friend and the partner of his counsels in political matters affecting the interests of the Church. Immediately afterwards, the question of Catholic emancipation was brought to a crisis by the menacing power of the Catholic Association and the election of O'Connell for the county of Clare. Mr Peel expressed to the Duke of Wellington his conviction that the Catholic question must be settled. The Duke consented. The consent of the king, which could scarcely have been obtained except by the Duke and Mr Peel, was extorted, withdrawn (the ministers being out for a few hours), and again extorted; and on the 5th of March 1829, Mr Peel proposed Catholic emancipation in a speech of five hours and a half, which was listened to with unflagging attention, and concluded amidst cheers which were heard in Westminster Hall. The apostate was overwhelmed with obloquy. Having been elected for the University of Oxford as a leading opponent of the Catholics, he had thought it right to resign his seat on being converted to emancipation. His friends put him again in nomination, but he was defeated by Sir R. H. Inglis, though the great majority of distinction and intellect was on his side. He took refuge in the close borough of Westbury, whence he afterwards removed to Tamworth, for which he sat till his death—preferring that secure and friendly connection to the offers of larger constituencies. Catholic emancipation was forced on Mr Peel by circumstances; but it was mainly owing to him that the measure was thorough, and unclogged by invidious conditions. This great concession, however, did not save the Tory government. The French Revolution of July 1830 gave fresh strength to the movement against them, though, schooled by the past, they promptly recognised King Louis Philippe. The parliamentary reform movement was joined by some of their offended Protestant supporters. The Duke of Wellington committed them fatally against all reform, first by cashiering Mr Huskisson for voting in favour of giving the forfeited franchise of East Retford to Birmingham, and then by a violent anti-reform declaration in the House of Lords. The elections went against them on the demise of the Crown; they were compelled, by popular feeling, to

put off the king's visit to the city; they were beaten on Sir H. Parnell's motion for a committee on the civil list, and resigned.

While in office, Mr Peel succeeded to the baronetcy, Drayton Manor, and a great estate, by the death of his father, May 3, 1830. The old man had lived to see his fondest hopes fulfilled in the greatness of his son; but he had also lived to see that a father must not expect to fix his son's opinions,—above all, the opinions of such a son as Sir Robert Peel, and in such an age as that which followed the French Revolution.

The ability and obstinacy of Sir Robert Peel's opposition to the Reform Bill won back for him the allegiance of his party. His opposition was able and obstinate; but it was temperate, and not such as to inflame the fierce passions of the time, delay the return of civil peace, or put an insurmountable barrier between his friends and the more moderate among their opponents. Once only he betrayed the suppressed fire of his temper. It was in the famous debate of the 22d April 1831, when his speech was broken off by the arrival of the king to dissolve the Parliament which had thrown out reform. He refused to join the Duke of Wellington in the desperate enterprize of forming a Tory government at the height of the storm, when the Grey ministry had gone out on the refusal of the king to promise them an unlimited creation of peers. By this conduct he secured for his party the full benefit of the reaction which was sure, and which he no doubt knew was sure, to ensue. The general election of 1832, after the passing of the Reform Bill, left him with barely a hundred followers in the House of Commons; but this handful rapidly swelled under his management into the great Conservative party. He frankly accepted the Reform Act, stamped it as final, taught his party to register instead of despairing, appealed to the intelligence of the middle classes, whose new-born power he appreciated, steadily supported the Whig ministers against the Radicals and O'Connell, and gained every moral advantage which the most dignified and constitutional tactics could afford. The changes which the Reform Bill necessarily drew with it, such as municipal reform, he rather watched in the Conservative interest than strongly opposed. To this policy, and to the great Parliamentary powers of its author, it was mainly due that, in the course of a few years, the Conservatives were as strong in the reformed Parliament as the Tories had been in the unreformed. It is vain to deny the praise of genius to such a leader, though his genius may have been of a practical, not of a speculative or imaginative kind. Nor is it wonderful if the skill of such a pilot, and a pilot who had steered for many years over such waters, sometimes resembled craft. His skill sometimes resembled craft; but the Duke of Wellington's emphatic eulogy on him was, "Of all the men I ever knew, he had the greatest regard for truth." The Duke might have added that his own question, "How is the King's government to be carried on in a reformed Parliament?" was mainly solved by the temperate and constitutional policy of Sir Robert Peel, and by his personal influence on the debates and proceedings of the House of Commons during the years which followed the Reform Act.

In 1834, on the dismissal of the Melbourne ministry, power came to Sir Robert Peel before he expected or desired it. He hurried from Rome at the call of the Duke of Wellington,—whose sagacious modesty knew his superior in politics, and yielded him the first place,—and became Prime Minister, holding the two offices of First Lord of the Treasury and Chancellor of the Exchequer. He vainly sought to include in his cabinet the two recent seceders from the Whigs, Lord Stanley and Sir James Graham. A dissolution gave him a great increase of strength in the House, but not enough. He was beaten on the election of the Speaker at the opening of the session of 1835, and, after struggling on for six weeks longer, was finally beaten, and resigned on the question of appropriating the surplus revenues of the Church in Ireland to national education. His time had not yet come; but the capacity, energy, and resource he displayed in this short tenure of office raised him immensely in the estimation of the House, his party, and the country. Of the great budget of practical reforms which he brought forward, the plan for the commutation of tithes, the ecclesiastical commission, and the plan for settling the question of dissenters' marriages, bore fruit, then or afterwards. His scheme for settling the question of dissenters' marriages, framed in the amplest spirit of liberality, was a striking instance of his habit of doing thoroughly and without reserve that which he had once made up his mind to do.

From 1835 to 1840 he pursued the same course of patient and far-sighted opposition, the end of which, sure, though distant, was not only office, but power. In 1837 the Conservative members of the House of Commons, with victory now in sight, gave their leader a grand banquet at Merchant Taylors' Hall, where he proclaimed, in a great speech, the creed and objects of his party. In 1839, the Whigs being beaten on the Jamaica question, he was called on to form a government, but failed, through the refusal of the Queen, by advice of Lords John Russell and Palmerston, to part with the ladies of her bedchamber, whom he believed, or professed to believe it essential to replace by ladies not connected with his political opponents. His time was not even yet fully come. In 1840 he was hurried, it is believed, by the ardour of his followers, into a premature motion of want of confidence, which was brought forward by Sir John Yarde Buller, and failed. But in the following year a similar motion was carried by a majority of one, and the Whigs were compelled to appeal to the country. The result was a majority of ninety-one against them, on a motion of want of confidence in the autumn of 1841; upon which they resigned; and Sir Robert Peel becoming First Lord of the Treasury, with a commanding majority in both Houses of Parliament, the country in his favour, and a staff of colleagues and subordinates unrivalled perhaps in the annals of English administrations, grasped with no doubtful grasp the reins of power.

The crisis called for a master-hand. The finances were in disorder. For some years there had been a growing deficit, which for 1841 was upwards of two millions, and attempts to supply this deficit by additions to assessed taxes and customs duties had failed. Distress and discontent reigned in the country, especially among the trading and manufacturing classes. The great financier took till the spring of 1842 to mature his plans. He then boldly supplied the deficit by imposing an income-tax on all incomes above a certain amount. He accompanied this tax with a reform of the tariff, by which prohibitory duties were removed and other duties abated on a vast number of articles of import, especially the raw materials of manufactures and prime articles of food. The increased consumption, as the reformer expected, countervailed the reduction of duty. The income-tax was renewed, and the reform of the tariff carried still further on the same principle, in 1845. The result was, in place of a deficit of upwards of two millions, a surplus of five millions in 1845, and the removal of seven millions and a half of taxes up to 1847, not only without loss, but with gain to the ordinary revenue of the country. The prosperous state of the finances and of public affairs also permitted a reduction of the interest on a portion of the national debt, giving a yearly saving at once of L.650,000, and ultimately of a million and a quarter to the public. In 1844 another great financial measure, the Bank Charter Act, was passed, and, though severely controverted, and twice suspended at a desperate crisis, has ever since regulated the currency of the country. In Ireland, O'Connell's agi-

tation for the repeal of the Union had now assumed threatening proportions, and verged upon rebellion. The great agitator was prosecuted, with his chief adherents, for conspiracy and sedition; and though the conviction was quashed for informality, Repeal was quelled in its chief. At the same time a healing hand was extended to Ireland. The Charitable Bequests Act gave Roman Catholics their fair share in the administration of charities, and legal power to endow their own religion. The allowances to Maynooth were largely increased, notwithstanding violent Protestant opposition. Three queen's colleges, for the higher education of all the youth of Ireland, without distinction of religion, were founded, notwithstanding violent opposition, both Protestant and Roman Catholic. The principle of toleration, once accepted, was thoroughly carried out. The last remnants of the penal laws were swept from the statute-book, and justice was extended to the Roman Catholic Church in Canada and Malta. In the same spirit acts were passed for clearing from doubt Irish Presbyterian marriages, for quieting the titles of a large number of Dissenters' chapels in England, and removing the municipal disabilities of the Jews. The grant for national education was trebled, and an attempt was made, though in vain, to introduce effective education clauses into the factory bills. To the alienation of any part of the revenues of the Established Church, Sir Robert Peel, a Conservative to the last, never would consent; but he had issued the Ecclesiastical Commission, and he now made better provision for a number of populous parishes by a redistribution of part of the revenues of the church. The weakest part of the conduct of this great government, perhaps, was its failure to control the railway mania by promptly laying down the lines on a government plan. It had prepared a palliative measure in 1846, but was compelled to sacrifice this, like all other secondary measures, to the repeal of the Corn Laws. It failed also, though not without an effort, to avert the great schism in the Church of Scotland. Abroad it was as prosperous as at home. It had found war in China and disaster and disgrace in Affghanistan. It speedily ended the war in China with success, and that in Affghanistan with honour. By the hand of its Governor-General of India, the invading Sikhs were destroyed upon the Sutlej. M. Guizot has said that the objects—not only the ostensible, but the real objects—of Sir Robert Peel's foreign policy were peace and justice among nations. The angry and dangerous questions with France touching the right of search, the war in Morocco, and the Tahiti affair, and the angry and dangerous questions with the United States touching the Maine boundary and the Oregon territory, were happily settled by frank and patient negotiation. In this, and in other parts of his administration, Sir Robert Peel was well seconded by the ability of his colleagues; but the Premier himself was the soul of all.

But there was a canker in all this greatness. There were malcontents in Sir Robert Peel's party whose presence often caused embarrassment, and twice collision and scandal. The Young Englanders disliked him because he had hoisted the flag of Conservatism instead of Toryism on the morrow of the Reform Bill. The strong philanthropists and Tory Chartists disliked him because he was a strict economist and an upholder of the new poor law. But the fatal question was protection. That question was being fast brought to a crisis by public opinion and the Anti-Corn Law League. Sir Robert Peel had been long in principle a free trader. Since his accession to power a new responsibility had fallen on him, which compelled him to think less of a class and more of the people. He had expressed to M. Guizot a deep, nay, a passionate conviction that something must be done to relieve the suffering and precarious condition of the labouring classes. He had lowered the duties of the sliding scale, and thereby caused the secession from the cabinet of the Duke of Buckingham. He had alarmed the farmers by admitting foreign cattle and meat under his new tariff, and by admitting Canadian corn. He had done his best in his speeches to put the maintenance of the corn laws on low ground, and to wean the landed interest from their reliance on protection. But to protection the landed interest remained wedded; and it is hard to say how far Sir Robert Peel himself dreaded the consequences of repeal to the steadiness of prices and to mortgaged estates. The approach of the Irish famine in 1845 decisively turned the wavering balance. The ports must be opened, and being opened, they could not again be closed. The Clare election and Catholic Emancipation were played over again. Sir Robert proposed to his cabinet the repeal of the corn laws. Lord Stanley and the Duke of Buccleuch dissented, and Sir Robert resigned. But Lord John Russell failed to form a new government. Sir Robert again came into office; and now, with the consent of all the cabinet but Lord Stanley, who retired, he, in a great speech on the 27th January 1846, brought the repeal of the Corn Laws before the House of Commons. In the long and fierce debate that ensued he was overwhelmed, both by political and personal enemies, with the most virulent invective, which he bore with his wonted calmness, and to which he made no retorts. His measure was carried; but immediately afterwards the offended Protectionists, goaded by Lord George Bentinck and Mr Disraeli, coalesced with the Whigs, and threw him out on the Irish Coercion Bill. He went home from his defeat, escorted by a great crowd, who uncovered as he passed, and immediately resigned. So fell a Conservative government, which would otherwise have probably ended only with the life of its chief. Those who overthrew Sir Robert Peel have dwelt on what they naturally believe to have been the bitterness of his fall. It is certain that he was deeply pained by the rupture with his party; but it is doubtful whether otherwise his fall was so bitter. For evening had begun to steal over his long day of toil; he had the memory of immense labours gone through, and of great things achieved in the service of the state; he had a kingly position in the country, great wealth, fine tastes, and a happy home.

Though out of office he was not out of power. He had "lost a party, but won a nation." The Whig ministry which succeeded him leant much on his support, with which he never taxed them. He joined them in carrying forward free trade principles by the repeal of the Navigation Laws. He joined them in carrying forward the principle of religious liberty by the bill for the emancipation of the Jews. One great measure was his own. It was the Encumbered Estates Bill for Ireland, which transferred the land of that country from ruined landlords to solvent owners capable of performing the duties of property towards the people. While in office he had probed, by the Devon Commission of Inquiry, the mortal sore which the Encumbered Estates Act healed. On the 28th of June 1850 he made a great speech on the Greek question against Lord Palmerston's foreign policy of interference. This speech being against the government, was thought to show that he was ready to return to office. It was his last. On the following day he was thrown from his horse on Constitution Hill, and mortally injured by the fall. Three days he lingered in all the pain which the quick nerves of genius can endure. On the fourth (July 2, 1850) he took the sacrament, bade a calm farewell to his family and friends, and died; and a great sorrow fell on the whole land. All the tributes which respect and gratitude could pay were paid to him by the Sovereign, by parliament, by public men of all parties, by the country, by the press, and, above all, by the great towns and the masses of the people to whom he had given "bread unleavened with injustice." He would

have been buried among the great men of England in Westminster Abbey, but his will desired that he might be laid in Drayton church. It also renounced a peerage for his family, as he had before declined the garter for himself when offered him by the Queen through Lord Aberdeen.

Those who judge Sir Robert Peel will remember that he was bred a Tory in days when party was a religion; that he entered parliament a youth, was in office at twenty-four, and secretary for Ireland at twenty-five; that his public life extended over a long period rife with change; and that his own changes were all forwards and with the advancing intellect of the time. They will enumerate the great practical improvements, and the great acts of legislative justice of those days,—Catholic emancipation, freedom for Dissenters, free trade, the great reforms in police, criminal law, currency, finance, the Irish Encumbered Estates Act, even the encouragement of agricultural improvement by loans of public money,—and consider how large a share Sir Robert Peel had, if not in originating, in giving thorough practical effect to all. They will consider, that of what he did nothing has been undone. They will reflect that, as a parliamentary statesman he could not govern without a party, and that it is difficult to govern at once for a party and for the whole people. They will compare his administration with those that preceded and those that followed, and the state and fortunes of his party when he was at its head, with its state and fortunes after his fall. They will think of the peace and good-will which his foreign policy diffused over Europe. They will think of his ardent love of his country; of his abstinence from intrigue, violence, and faction; of his boundless labour through a long life devoted to the public service. Whether he was a model of statesmanship may be doubted. Models of statesmanship are rare, if by a model of statesmanship is meant a great administrator and party leader, a great political philosopher, and a great independent orator, all in one. But if the question is, whether he was a ruler loved and trusted by the English people, there is no arguing against the tears of a nation.

Those who wish to know more of him will consult his own posthumous Memoirs, edited by Lord Mahon and Mr Cardwell, his literary executors; the four volumes of his Speeches; M. Guizot's *Sir Robert Peel;* Künzel's *Leben und Reden Sir Robert Peel's;* Mr Disraeli's *Life of Lord George Bentinck;* and *The Right Honourable Benjamin Disraeli, M.P., a Literary and Political Biography*, by an anonymous author; as well as the general histories of the time, particularly those of Sir Archibald Alison and Miss Martineau. (G. S.)

PEEL, a market-town and seaport on the west coast of the Isle of Man, 15 miles W.N.W. of Douglas, N. Lat. 54. 14., W. Long. 4. 42. The cathedral of St Germains in the town is now only used as a burying-place; but there is a modern parish church, a Methodist chapel, a grammar-school, and other educational establishments. On a small rocky island, separated from the town by a narrow channel, very shallow at low-water, stands an ancient castle, which occupies a large extent of ground, and contains within its area an old church of St Patrick. The harbour has a pier and a lighthouse; but it is now much neglected. Pop. (1851) 2342.

PEELE, George, an English dramatist of the Elizabethan age, is said to have been born in Devonshire in 1552 or 1553. He was a member of Broadgates Hall (now Pembroke College), Oxford, in 1564. He took his bachelor's degree in 1577; and was made Master of Arts in 1579. Soon after this date, and with the reputation, according to Anthony Wood, of being "a most noted poet in the university," young Peele repaired to the metropolis, adopted the profession of authorship, and occasionally tried his hand at the histrionic art. He seems to have enjoyed a tolerable share of the distinction ordinarily accorded to poets of his time,—viz., extreme poverty. He associated with Marlowe, Greene, Nash, Lodge, and Watson, and seems to have mingled as eagerly in the dissipations of the metropolis as the most dissolute of those gifted men. Peele's character has doubtless suffered, however, from the absurd and obviously fictitious tract entitled *The Merrie Conceited Iests of George Peele*, which represents him as a low and vulgar sharper, rejoicing in rascality, and glorying in the meanest frauds. It is doubtless a counterpart to *Ben Johnson's Jests*, or the yet more preposterous *Merry and Diverting Exploits of George Buchanan, commonly called the King's Fool.* Honest old Dekker introduces us to Peele and his set in the Elysian fields amid the "Grove of Bay Trees," where, seated amid thick laurel, by a stream "that made music in the running," "from them came forth such harmonious sounds that birdes build nests onely in the trees there to teach tunes to their young ones prettily." Peele was not the sweetest singer there, however, for young Kit Marlowe was among them. The date of Peele's death is unknown. He was dead in 1598, as appears from the *Palladis Tamia* of Francis Meres, who informs us, with what truth it is difficult to say, that his end was hastened by his vices.

The earliest of Peele's productions known to us is a copy of verses prefixed to Watson's Ἑκατομπαθία, published about 1581. Besides a number of miscellaneous poems, some of them possessing very great merit, speeches for pageants, &c., we find in Mr Dyce's collection of Peele's writings six dramas in all, but forming not more, in the estimation of that judicious critic, than one-half of his entire dramatic works. In 1584 his pastoral drama of the *Arraignment of Paris* was printed anonymously; but the allusion to it by Peele's friend Nash, in the Preface to Greene's *Arcadia*, 1587, leaves no doubt as to the authorship. *The Famous Chronicle History of King Edward I.* appeared in 1593, and possesses much interest, as well from its extravagance as from its occasional tragic energy. In 1594 was published the anonymous tragedy of *The Battle of Alcazar*, which Malone and Dyce, with some hesitancy, agree in ascribing to Peele. *The Old Wives Tale, a pleasant conceited Comedie*, had been frequently performed before 1595, when it was first published; and possesses the interest of having partly furnished Milton with the plan and character of his *Comus.* It is highly imaginative, but disfigured by buffoonery and extravagance. Peele's greatest performance, *The Love of David and Fair Bethsabe, with the Tragedy of Absolon*, was first printed in 1599, and is characterized by Thomas Campbell (*Spec. of Brit. Poets*, vol. i.) as "the earliest fount of pathos and harmony that can be traced in our dramatic poetry." Charles Lamb, while not quite so enthusiastic about "this canticle of David," has nevertheless rendered the "kingly bower, seated in hearing of a hundred streams," familiar to all readers. (See *Specimens of Eng. Dram. Poets.*) *The Historie of the Two Valiant Knights Sir Clyomon and Sir Clamydes*, printed anonymously in 1599, is attributed to Peele by Mr Dyce, partly on the faith of a manuscript marking on the title-page of an old copy, and partly on internal evidence. Such are the remains of what gained Peele his fame as a dramatist among his contemporaries. "His comedies and tragedies," says Wood, "were often acted with great applause, and did endure reading with due commendation many years after their author's death." (*Athenæ Oxonienses*, vol. i., p. 688.) Peele's close relation to Marlowe and Greene naturally provokes comparison with them. While not to be named beside Marlowe in respect to the depth and power of his tragic genius, and while decidedly below Greene in comic power, he nevertheless deserves a higher place than either as a felicitous versifier. Thomas Campbell alleges,—"There is no such

sweetness of versification and imagery to be found in our blank verse anterior to Shakspeare." (See *The Works of George Peele, with some Account of his Life and Writings*, by Rev. Alex. Dyce, 2 vols., 1828. Improvements and additions appeared with the reprint of 1829; and in 1839 a third volume was added by the same editor.)

PEERS. See NOBILITY, and PARLIAMENT.

PEGASUS. See BELLEROPHON.

PEGAU, a town of Saxony, in the circle of Leipsic, on the left bank of the Elster, 14 miles S.S.W. of Leipsic. It is surrounded by walls; and its chief public building is the handsome church of St Lawrence, containing several monuments. Pop. 3946.

PEGO, a town of Spain, in the province of Alicante, 44 miles N.E. of the town of that name. It is generally clean and well built, and has a court-house, church, schools, hospitals, &c. Woollen stuffs are manufactured here; and there are mills for rice, flour, and oil. Pop. 5565.

PEGU, a British province of Eastern India, lying between N. Lat. 15. 49. and 19. 30., E. Long. 94. 11. and 96. 55., is bounded on the N. by the Burmese empire, E. by the Tenasserim provinces (from which it is separated by the River Sitang), S. by the Gulf of Martaban, and W. by the Bay of Bengal and the province of Arracan; the latter divided from it by the Youmadoung Mountains; length, from N. to S., about 240 miles; breadth, 170. The country is in general level, though it is traversed by several chains of hills. It is watered by the Irawaddy, which flows southwards from Burmah, and falls into the Gulf of Martaban, forming a large delta. The soil is fertile; but agriculture has been much neglected since the conquest of Pegu by the Burmese. Rice is the principal crop raised; and teak timber is also obtained. Tigers, elephants, buffaloes, and deer are the animals that mostly throng the forests and jungles of Pegu. Iron, tin, and lead, as well as rubies, sapphires, and other jewels, are obtained in this country. The government of Pegu is similar to that of the adjacent provinces of Tenasserim and Arracan. The province is divided into six districts, and contains 570,180 inhabitants.

The early history of Pegu consists of little more than a narrative of barbarous and cruel contests between that country and the kingdom of Ava, in which the latter was finally successful, and reduced Pegu to a province of that kingdom, or, as it is generally called, the Burman Empire. The most important events in these wars, as well as those which led to the more recent contests of Burmah with Great Britain, and the addition of Pegu to the British empire, are narrated in the article BURMAH.

The principal towns in the province are Pegu, Prome, and Rangoon, all of which are fortified. Martaban stands on the E. bank of the Salween, 10 miles N.W. of Moulmein. It is built on the slope of a hill, and has several large temples. Though surrounded with a wooden stockade, and protected by a stone battery near the river, the place is not of great strength. It was taken by the British in the Burmese war in 1852, being the first town that fell in that war. Pop. about 6000.

PEGU, the chief town of the above district, stands on the left bank of a river of the same name that flows into the Irawaddy, 58 miles N.E. of Rangoon. It is built in the shape of a quadrangle, and the streets are broad and regular, crossing each other at right angles. The streets are paved with bricks, and the houses, which are built of wood, are elevated on posts above the ground. Of the buildings in the town, the most important is the temple of Shoemadoe, a brick structure, octagonal at the base, and rising in the form of a pyramid or spire. Pegu was destroyed in 1757 by the Burmese, on their final triumph over the country, but it was subsequently rebuilt. In 1824 it was captured by the British, but restored on the conclusion of the first war with Burmah. In 1852 it was again taken, and has since that time been retained. It is said to have contained at one time 150,000 inhabitants.

PEILAU, a town of Prussian Silesia, government of Breslau, and 33 miles S.S.W. of that town. The inhabitants, amounting to 5235, are mostly Moravians, and are chiefly employed in the manufacture of linen and woollen goods.

PEINE FORTE ET DURE (Lat. *pœna fortis et dura*) signifies a species of torture inflicted by English law on those who, being arraigned of felony, refuse to put themselves on the ordinary trial, but stubbornly stand mute.

PEINT, with HURSOOL, a small native state of India, in the presidency of Bombay, is bounded on the N. by the states of Dhurrumpore and Daung, E. by the British district of Ahmednuggur, S. by that of Tannah, and W. by those of Tannah and Surat; length, 46 miles; breadth, 28; area, 750 square miles. As the last rajah died leaving only a daughter, the state is at present managed by the British in trust for her and her children. Pop. 55,000.

PEIPUS. See LIVONIA.

PEIRESC, NICOLAS-CLAUDE-FABRI, *Seigneur de*, born in 1580 at Beaugensier in Provence, was descended from an ancient and noble family which had been originally established at Pisa in Italy. From Avignon, where he had spent five years at the Jesuits' college, he was in 1595 removed to Aix, and entered upon the study of philosophy. It was here, while in the eager pursuit of literature, that his attention was first directed to antiquarian studies by accidentally meeting with a medal of the Emperor Arcadius. On removing to the Jesuits' college at Tournon in 1596, for the study of cosmography, he enjoyed the valuable assistance of Petrus Rogerus, a skilful numismatist. Being recalled by his uncle in 1597, he returned to Aix, and there entered upon the study of the law, relieving the tedium by frequent visits to Bagarr, a most skilful antiquary, afterwards master of the jewels to Henri IV. He visited Italy in 1599, proceeded to Montpellier in 1602, and thence to Aix in 1603, to receive the senatorial dignity just vacated by his uncle.

In the year 1605 he visited Paris, whence he, in 1606, proceeded to England in company with the king's ambassador. He was very graciously received by King James I.; and having seen Oxford, and visited Camden, Sir Robert Cotton, Sir Henry Saville, and other learned men, he passed over to Holland. During his residence in that country he made the acquaintance of Joseph Scaliger at Leyden, and Hugo Grotius at the Hague. On his return to Aix, he was chosen a councillor of the Parliament of that city, where he remained till his death, which occurred in 1637. The death of the "Procureur Géneral de la Littérature," as Bayle calls him, was lamented wherever letters were esteemed, and *eloge* upon *eloge* celebrated his merits in half the languages of Europe. A collection of these panegyrics has since been made, under the title of *Panglossia*. While no work at all proportioned to the learning and ability of the author remains to us, he nevertheless left behind him a vast mass of incomplete manuscripts on all manner of subjects. A catalogue of these MSS., 700 in all, is preserved in the British Museum among the papers of Sir Hans Sloane. A considerable number of the inedited letters of Peiresc appeared in the *Magasin Encyclopédique*, and were afterwards published separately, Paris, 1815. We have an elegant *Vita Nic. Claudii Fabricii de Peiresc*, by his warm friend Gassendi, 4to, Paris, 1641; translated into English by W. Rand, 1657; and into French by Requier in 1770. The Eloge of Peiresc by Lemontey was crowned by the Academy of Marseilles in 1785.

PEKALONGAN, a province of Java, bounded on the N. by the Java Sea, E. by the province of Samarang, S. by that of Banjoemas, and W. by that of Tegal; length,

 from E. to W., 30 miles; breadth, 18 miles. Though level near the coast, the interior of the province is hilly. The soil is well watered, and produces, among other things, coffee and rice. Manufactures of indigo and sugar are carried on. The province contains three seaports,—Pekalongan, Batang, and Pabean,—between which and Batavia a considerable trade is carried on. Pop. 224,000.

The town of Pekalongan, which stands on the coast at the mouth of a river of the same name, contains many well-built stone houses, and has an open roadstead. The Dutch have a government-house and a fort here.

PEKING, or PEKIN, the capital of the Chinese empire, and of the province of Chihli, stands in a sandy plain about 12 miles S.W. of the River Pei-ho, and about 100 W.N.W. of its mouth; N. Lat. 39. 54., E. Long. 116. 27. It is, in the opinion of the Chinese, one of their most ancient cities, and is known under various names. Previous to the conquest of the country by the Mongols it was called *Shuntien-fu*, or "The City obedient to Heaven;" but after that event, when it was made the capital, the name of *Khan-palik*, or "The City of the Khan," was given to it. The name *Peking* signifies "Northern Capital;" but it is generally designated on Chinese maps as *King-oz*, or "Capital of the Court." A tributary of the Pei-ho, called Tung-hwui-ho, flows through the city from the N.W., and supplies it with water. The circumference of the city and suburbs is estimated at 25 miles, and the area at 27 square miles; though other accounts limit the area to 14 square miles. The latter estimate probably includes only the city itself, and not the suburbs. Peking consists of two parts: the northern or Tartar city, called *Nui-ching;* and the southern or outer city, called *Wai-ching,* in which the Chinese live. Both these divisions are surrounded by walls 30 feet high, and about 20 feet broad at the base; but as the inner face is sloping, they are only 12 feet wide at the top. They consist for the most part of mounds of earth or rubbish faced with bricks. According to most of the plans, Peking is also surrounded with ditches; but this, though perhaps partially true, is certainly not the case with the N.E. portion. At intervals of about 60 yards along the outside of the walls stand square towers, projecting about 30 feet from the wall; and similar erections stand at each side of all the gates, connected by a semicircular rampart in front. The gateways consist of strong arches surmounted by wooden buildings several storeys high. The appearance of Peking from the outside is dull and uniform, as there are no spires, minarets, or pillars rising above the mass of the houses, which are roofed with yellow, green, or red tiles; and the only prominent objects are clumps of trees and the flag-staffs that rise in front of the houses of the officials. The roofs of the houses, however, present an appearance by no means unpleasing, as their sides and ridges are gently curved, and are adorned with various fantastic figures; and the whole glitters like gold in the rays of a bright oriental sun. The northern city consists of three separate inclosures, one within the other. The innermost, in which the imperial palace is situated, is called *Kin-Ching*, or the "Prohibited City." Within are the palaces and pleasure-grounds of the emperor and empress. The ground in this inclosure is not level, but is raised in artificial hills, on which the principal palaces are built. There are also large and deep artificial lakes, of irregular form, and interspersed with small islands. The buildings and grounds within the Prohibited City are said to be, in architecture and arrangement, far superior to anything else of the kind in China. To Sir George Staunton, who, when passing through Peking on an embassy to the imperial park of Yuen-ming-yuen, caught a glimpse of this portion of the city through the northern gates, the whole had the appearance of enchantment. Besides the imperial palaces and pleasure-grounds, the Prohibited City contains two halls and a fine marble gateway 110 feet high, ascended by five flights of stairs, where the emperor stands on certain occasions to receive the homage of his courtiers. On the east side stand the offices of the cabinet, the treasury, and the imperial library, consisting of 12,000 works; while towards the west is situated a variety of public and private buildings. The government of the palace is in the hands of a special council, which is divided into seven sections, having different duties. Attached to the court of Peking are three great scientific establishments: the National College, for the sons of the great dignitaries; the Imperial College of Astronomy, by which the annual almanacs are prepared; and the College of Medicine. There is published daily at Peking an official gazette of 60 or 70 pages. It is entirely under the control of the emperor, to whom everything that is printed in it must be presented. The population of the Prohibited City is not very great, and it consists principally of Manchoos. Outside of this inclosure is another called *Hwang-Ching*, or the "Imperial City," not so sacred as the former, but entered only by authorized persons. It is about 2 square miles in extent, and is surrounded by a wall covered with yellow tiles, and known as the Imperial or Yellow Wall. From the southern gate a broad street leads up to the Prohibited City, on the right of which stands the *Tai-Miau*, or "Temple of the Imperial Ancestors," an extensive collection of buildings surrounded by a wall; and on the left an altar of a peculiar construction dedicated to the gods of land and grain, on which the emperor alone is allowed to sacrifice. The Imperial City also contains numerous temples to various subordinate Chinese deities; and it has been calculated that there are in this and the interior inclosure upwards of 200 palaces, all of great size. The Tartar city, lying outside of the divisions already described, has several broad and straight streets crossing each other at right angles. Near the southern gate of the imperial wall are the principal tribunals and government offices in the city; and not far off is the college of the Russian mission, which consists of ten members sent periodically from St Petersburg. On the wall at the S.E. corner of this part of the city stands the observatory, provided with instruments by the Emperor Kanghi, under the direction of Roman Catholic missionaries, and now under the care of Chinese astronomers. Not far from this building is the hall for literary examinations, where the candidates for degrees assemble. In the north part of the town is a lofty tower, forming one of the most conspicuous objects in Peking, and containing a huge cylindrical bell and a large drum, both of which are used to mark the watches of the night. The town contains many places of worship belonging to different religions and sects, including a Greek and a Latin church, and a Mohammedan mosque, besides numerous temples of the various forms of Budhism. Among the last is one where the deceased kings and emperors are worshipped; and another called the White Pagoda, a tastefully-ornamented building, having a fine obelisk in front of it. The outer or Chinese city, which is about the same size as the other, though more populous, is not in general so well built, and contains few large buildings. Two extensive portions of the area are occupied by the large inclosures surrounding the altars to Heaven and to Agriculture, which stand, the one to the right and the other on the left of the central street leading from the south gate to the Tartar city. The former, on the east side, consists of three circular terraces, each 10 feet high, and in succession 120, 90, and 60 feet in diameter. They are all paved with marble, and surrounded with balustrades. In connection with this altar is the Palace of Abstinence, where the emperor, who is the priest of the altar, fasts for three days before offering the annual sacrifice at the winter solstice. On the opposite side of the street from this altar is another inclosure containing four altars, dedicated respectively to the spirits of heaven, to those of the earth, to the planet

Jupiter, and to the monarch Shinnung, who is regarded as the inventor of agriculture. To the west of these altars is an artificial pool, called the Black Dragon Pool, dedicated to the spirits of the waters, which also occupies a large space. Beyond the walls of the city stands, on the east side, an altar to the sun, and on the west, one to the moon; while about eight miles to the N.W., in an undulating country, is the park of Yuen-ming-yuen, containing numerous imperial residences and a hall of audience. In one of the most beautiful situations near Peking is a French burying-ground; but this has been much defaced by the Chinese. The principal streets of Peking, which are generally straight, leading from one gate across the city to another, are about 100 feet broad, and the lowness of the houses with which they are lined serves to increase their apparent width. They are unpaved, probably on account of the difficulty of obtaining stone in the vast plain in which the city stands. During the summer they are kept well sprinkled with water, but in wet weather they are exceedingly muddy. The smaller thoroughfares, like those of most Chinese cities, are mere narrow lanes. The principal streets are lined with shops, which are entirely open in front during the day, and have on each side sign-boards fastened in stone bases, and reaching as high as the eaves, painted with large ornamental characters, and sometimes decorated with flags of various colours. The fronts of the houses are also frequently painted in brilliant colours, which gives the streets a very gay and lively appearance. At the intersections of the principal streets there are tablets and portals erected in honour of distinguished persons. The main thoroughfares are feebly lighted during the night by lanterns hung in front of the houses; and those who go about in the dark carry lanterns or torches. People belonging to all the various tribes of Central Asia, in their various costumes, throng the streets of Peking; and the number of Manchoo women who are to be seen in the streets, on foot and on horseback, gives to the city an appearance different from that of those in the south of China. Horses and carriages are used as means of conveyance, and are to be had for hire; but sedans, which are elsewhere in China the usual conveyances, are not permitted so near the emperor, except for privileged persons. The streets, though broad, are much blocked up by the moveable workshops of various mechanics, the tents and booths filled with all kinds of merchandise, and the various wares laid out in front of the shops; so that there is only a narrow road left in the middle, along which there are continually passing official, funeral, and bridal processions; strings of dromedaries, with coals from Tartary; carts and wheel-barrows laden with vegetables. The sides of the streets are also filled with crowds of people buying and selling, whose varied appearance and confused sounds give to the place a busy and animated appearance. Few manufactures and no trade is carried on at Peking: the city is supplied with provisions chiefly from the southern provinces, and from the flocks raised in the northern part of Chihlí; and the adjacent country produces but a small quantity of the provisions required. The government of Peking is not subordinate to the provincial magistrate, but only to the emperor himself. There is a regular police, who patrol the streets by night beating together two hollow bamboos to mark the time. The climate is colder in winter than that of most other places in the same latitude; and the houses are warmed by flues under the rooms; but fuel is very scarce and dear. A large proportion of the inhabitants of Peking are poor, and they frequently rise in mobs, and pillage the granaries to supply themselves with food. To keep the capital quiet is an object of much care to the government, as the state of the whole empire depends very much on that of Peking. The population of Peking is variously estimated from 1,300,000 to 3,000,000. It probably amounts to 2,000,000, or nearly that of London. (Barrow's *Travels;* Gutzlaff's *China Opened; The Middle Kingdom,* Williams; Davis' *China,* new edition, 1857.)

PELAGIUS, the founder of the sect of the *Pelagians*, is supposed to have been a native of Britain, and first appears on the stage of history as a monk, residing at Rome, about the beginning of the fifth century. He was at that time a man of great moral earnestness. His adherence to the monkish rules was rigid, his efforts to reform both clergy and laity assiduous, and his sanctity well spoken of in all the churches. Yet it was this same deep regard for morality which was the occasion of Pelagius's lapse into error. Looking down from the height of his own self-righteousness, he was scandalized to see the majority of professing Christians grovelling carelessly and contentedly in every kind of sensuality. With all the intensity of his reforming zeal, he set himself to discover the cause and remedy of this moral disease. The cause, it occurred to him, was the trust which was placed throughout the church in the efficacy of the sacraments, and the sufficiency of faith. The remedy, he thought, would be a creed which should hold man's salvation to be dependent upon his own exertions. To develop such a creed into a regular and consistent form became his next endeavour. As the foundation of his system, he assumed that a just God could not visit the iniquities of one man upon the heads of others. On this was established the dogma, that the effects of Adam's first sin were confined to himself, and did not descend to his posterity. Accordingly death, and the other evils of life, were not the signs of a blighted spirit, but the necessary incidents of a body made of dust. Men therefore came into the world pure and innocent. Baptism, though needful to admit them into the kingdom of heaven, was not needful to cleanse them from moral pollution, or to insure their eternal blessedness. Nor was inward grace necessary to predispose them to love and obey the commandments of God. All the grace that they required was the privilege of exercising their natural faculties, of using the advantages of the gospel and the church, and of receiving forgiveness for any sins they might commit. With these aids alone they could confidently address themselves to the observance of the law. Their own free-will was able to choose the good, and their own strength was able to accomplish it. If they should step aside from the right path through ignorance or forgetfulness, they would not be culpable. Even if they should really become corrupt, they could convert themselves by their own exertions. Thus was a man's own righteousness, and not his faith, declared to be the means of his salvation.

This flagrant heresy being propagated in Palestine by Pelagius himself, and in Africa by his friend and disciple Cœlestius, soon provoked opposition. Cœlestius was excluded from the fellowship of the church by a synod held at Carthage in 412. Pelagius was arraigned before two ecclesiastical councils, held respectively at Jerusalem and Diospolis in 415. Although at both of these tribunals he succeeded in baffling his accusers, and deceiving his judges with sophistry and equivocation, yet he could not altogether lull the suspicions of the orthodox. The North African bishops, led on by Augustine, commenced a deadly attack with books, letters, and edicts. In 417 they induced Pope Innocent I. to anathematize the rising heresy; in 418 they issued a formal edict against it from an assembly held at Carthage; and not long afterwards they prevailed upon the emperor to promulgate several decrees threatening the new sect with confiscation and banishment. The result was, that Pope Zosimus was forced to condemn the obnoxious doctrine; several ecclesiastical councils throughout Europe approved the sentence; Pelagius retired into exile, and went off the arena of history; and Pelagianism was nipt

in the bud, and was deprived of all existence as a formal confession of faith.

Of the numerous works of Pelagius, the following alone have been authenticated:—*Expositionum in Epistolas Pauli Libri XIV.; Epistola ad Demetriadem*, and *Libellus Fidei ad Innocentium Papam.* They are all included in the best editions of Jerome. (For an account of Pelagius and Pelagianism, see Augustine's *De Gestis Pelagii;* G. J. Vossius' *Historia Controversiarum Pelagianarum;* the Church Histories of Neander, Milner, Gieseler, and Waddington; Hagenbach's *History of Doctrines;* Patouillet's *Vie de Pélage*, 1751; N N. Leutzen's *Dissertatio de Pelagianorum Doctrinæ Principiis*, Colon. Agr., 1833; and Wiggers' *Pragmatische Darstellung des Augustinismus und Pelagianismus*, 2 vols., Hamb. 1833. This last work has been translated into English by Professor Emerson, 8vo, New York, 1840.)

PELAGIUS I., Pope, succeeded Virgilius in the Roman see in 555, and died in 560.

Pelagius II., *Pope*, succeeded Benedict I. in 578, and died in 590.

PELASGI (Πελασγοί), an ancient race, believed to have been widely spread over Greece and Italy in pre-historic times, but of whom scarcely anything definite is known. The name *Pelasgi* owes its derivation, according to tradition, to Pelasgus, father of Lycaon, King of Arcadia, and reputed ancestor of the race. (Strabo, vii., p. 321.) Some maintain, however, that the genuine form of the word was Πελαργοί, which is variously derived (1.) from Ἄργός, *a plain*, in old Greek, and πέλω; (2.) from Ἀγρός, *a field*, and πελω; and, finally, from πελαργοί, *storks*, in allusion (3.) either to their wandering life, or (4.) to their rudeness of speech. Krase (*Hellas*) favours the first derivation, O. Muller (*Die Etrusker*) the second, Strabo and Myrsilus the third, and a writer in the *Philological Museum*, vol. i. ("On the names of the Antehellenic Inhabitants of Greece"), the fourth. Schwegler, the most recent writer who has ably taken up the entire question, is in considerable doubt whether the name Pelasgi is to be regarded as an ethnographic distinction, or as an epithet equivalent to *autochthones*, or aborigines (*Röm. Gesch.*) Nor is the origin of the Pelasgians better ascertained than their name. They are generally supposed to have immigrated from somewhere beyond sea, most probably from Asia Minor, by the Propontis and the Hellespont. The whole of Greece during the ante-Hellenic period was occupied by a number of barbarous tribes, of whom the most important were the Pelasgi, both as occupying a larger portion of the country than any other tribe, and from their wide diffusion into other territories. The whole of Hellas during this pre-historic age is said to have been more or less overrun by the Pelasgi. (Strabo, v., p. 220; Herodotus, ii. 56; viii. 44; Thucydides, i. 3.) The earliest notice of them, however (Homer, *Iliad*, ii. 681), represents them as having their chief abode in "Pelasgian Argos" in Thessaly. "That part of Thessaly," says Strabo, "is called Pelasgian Argos which extends from the coast between the outlet of the Peneus and Thermopylæ as far as the range of Pindus, because the Pelasgians were masters of that region." Epirus also, and especially Dodona, is made a chief abode of the Pelasgi by Homer, Hesiod, and Æschylus; the former informing us that Zeus was worshipped as the "Pelasgian king." Moving southward, we next find traces of the Pelasgi in Bœotia, and especially in Attica, where, according to Herodotus (vi. 137), Thucydides (ii. 17), and Strabo (ix., p. 401), they took up their abode at Athens, under Mount Hymettus, from which they were, however, afterwards expelled. Apart from the legend already referred to of the Arcadian origin of the Pelasgi, we find frequent mention, especially in Herodotus, Æschylus, and Strabo, of their presence in the Peloponnesus, and particularly of their intimate relation to Argolis. Two conflicting centres of emanation are thus assigned to this race,—that of Thessaly and Epirus, and that of Arcadia; but there are no satisfactory means of determining whether the one account or the other be correct. Another curious contradiction with respect to this race is noticed by Wachsmuth (*Hell. Alt.*, vol. i., part i.) Herodotus represents them as fixed and stationary (i. 56); while Strabo describes them as a moveable and migratory people (xiii. 3, § 3). Passing from the mainland of Greece we find marks of the presence of the Pelasgi in numerous islands of the Ægæan Sea. Homer alludes to them in Crete (*Odys.* xix. 175); Herodotus in Samothrace (ii. 51); Herodotus (v. 26), Strabo (v., p. 220), Thucydides (iv. 109), and Pausanias (vii. 2), in Lemnos and Imbros; Dionysius (i. 18) traces them to Lesbos; Herodotus (vii. 95) says that seventeen of the Ionian Islands were inhabited by Pelasgi; and Menecrates (Strabo, xiii., p. 621) assigned to them not only the islands of Ionia, but also the coast of Asia Minor. The latter portion of his statement is likewise confirmed by Homer, Herodotus, Strabo, and Dionysius. Herodotus (i. 57) found, in his own time, two Pelasgian cities, Scylace and Placia, on the Hellespont, and a place called Creston, probably in Macedonia, speaking similar dialects, differing from their neighbours around them, but not ordinary Greek (βάρβαρον γλῶσσαν ἱέντες). The historian quotes this fact in order to prove that the ancient language of the Pelasgi was a barbarous language, or distinct from that of the Hellenes. This passage in Herodotus has been the source of not a little controversy. Bishop Thirlwall is of opinion that the statement of Herodotus respecting the "barbarous" language of these Pelasgic communities simply means that they spoke a very bad Greek. "Nothing more," he says, "can be safely inferred from it, than that the Pelasgian language which Herodotus heard on the Hellespont and elsewhere sounded to him a strange jargon, as did the dialect of Ephesus to a Milesian, and as the Bolognese does to a Florentine. (*Hist. of Greece*, vol i., c. ii., p. 60.) Mr Grote, on the other hand, asserts that the meaning of Herodotus is unmistakeable as to the substantial difference of the Pelasgic language and the ordinary Greek. "The affirmation," he says, "of Herodotus is distinct and twice repeated, that the Pelasgians of these towns, and of his own time, spoke a barbaric language; and that word appears to me to admit but of one interpretation. To suppose that a man who, like Herodotus, had heard almost every variety of Greek in the course of his long travels, as well as Egyptian, Phœnician, Assyrian, Lydian, and other languages, did not know how to distinguish bad Hellenic from non-Hellenic, is in my judgment inadmissible." "I think it therefore certain," he again remarks, "that Herodotus pronounces the Pelasgians of his day to speak a substantive language different from Greek; but whether differing from it in a greater or less degree (*e.g.*, in the degree of Latin or of Phœnician), we have no means of deciding." (*Hist. of Greece*, vol. ii., pp. 351–353.) Mr Ellis, in an ingenious pamphlet (*Contributions to the Ethnography of Italy and Greece*, by Robert Ellis, B.D., London, 1858), adopts a similar interpretation of the Greek historian. He says at p. 5, "In describing, then, the Pelasgian language as barbarous, Herodotus gives us to understand to what language—namely, the Greek—he considered the Pelasgian to be substantially foreign." Grote simplifies the vexed Pelasgian question, by not presuming "to determine anything in regard to the legendary Pelasgians and Leleges, the supposed ante-Helenic inhabitants of Greece." "Whoever has examined," he says again, "the many conflicting systems respecting the Pelasgi, from the literal belief of Clavier, Larcher, and Raoul Rochette (which appears to me at least the most consistent way of proceeding), to the interpretative and half-incredulous processes applied by abler men, such as Niebuhr, or O. Müller, or Dr Thirlwall,

will not be displeased with my resolution to decline so insoluble a problem." (Vol. ii., pp. 347, 351.) In the opinion of the Rev. George Rawlinson (*History of Herodotus*, London, 1858, vol. i., p. 665), the statement of Mr Grote regarding the radical difference of the Greek and Pelasgic languages "is one of undue and needless scepticism. . . Anglo-Saxon is a barbarian or foreign tongue to a modern Englishman, and so is Gothic to a modern German, Provençal to a Frenchman, Syriac to a Chaldee or Mosul. The diversity between the Hellenic and the Pelasgic was probably of this nature, as Niebuhr, Thirwall, and C. O. Müller suppose. The nations were essentially of the same stock, the Hellenes having emerged from among the Pelasgi; and we may confidently pronounce on the Indo-European character of the latter from the fact, that the language of the former belongs to this family."

Traditions of the presence of the Pelasgi are not, however, limited to Greece; they are intimately connected likewise with the Italian peninsula. The fullest account of the primitive population of Central Italy is given by Dionysius. This writer represents (i. 11) Œnotrus, son of Lycaon, leading a colony into Italy seventeen generations before the Trojan war. He further informs us that Pelasgians came from Thessaly by sea, and landed in Italy at the mouth of the Po. Thence they moved southwards, taking some cities from the Umbrians, and were only withheld from attacking the aborigines by a response given to the Pelasgi by the Dondonian oracle. Becoming conciliated to the aborigines, the Pelasgi had a territory assigned them near Velia, and they subsequently aided their benefactors in expelling the Siceli or Siculi into the island Sicily, to which they gave their name. After a time, the historian continues, the Pelasgians returned to Greece in separate bodies, and from the name Tyrrhenia by which the western coast of Italy was known to the Greeks this race acquired the appellation of Tyrrhenian, and were designated Tyrrhenian Pelasgians. "These testimonies in Dionysius," says Clinton (*Fasti Hellenici*, vol. i., p. 28), "establish the *fact* that Pelasgi from Greece emigrated to Italy; but the *circumstances* and the *time* of that earliest migration are lost in remote antiquity." On this observation Sir G. C. Lewis comments by affirming, "The fact itself seems as uncertain as the circumstances and the time. Mr Clinton does not advert to the statement of Dionysius respecting a migration of Pelasgians back to Italy, which is an essential part of his narrative." (*On the Credibility of Early Roman History*, vol. i., p. 282, note.) Lewis further remarks that "this portion of the narrative of Dionysius is merely an ethnological legend. No authentic record of the migrations or acts of the Pelasgian people appears to have been accessible to the historians of antiquity." (Vol. i., p. 282.) Other testimonies besides that of Dionysius go to confirm the tradition of the immigration of the Pelasgians into Latium, and even assert the name of Rome itself to be Pelasgian. (See Lewis, vol. i., p. 395.) Indeed the whole of Italy, according to legendary record, was inhabited in ancient times by the Pelasgi. Founding on these genealogical and mythical traditions, Niebuhr has come to the conclusion, "not as an hypothesis, but with full historical conviction," that the Pelasgians were the primitive population both of Greece and of Italy. He says, "There was a time when the Pelasgians, perhaps the most extended people in all Europe, were spread from the Po and the Arno to the Bosphorus." (*Hist. of Rome*, vol. i., p. 25.) This race, he maintains, gradually disappeared because they became Hellenized. The Greek element in the Latin language he holds to be Pelasgic. Schwegler, who agrees in the main with Grote respecting the unauthentic character of the Pelasgic traditions, condemns the hypothesis of Niebuhr as entirely untenable. Lewis likewise maintains that the alleged records of the Pelasgians rest on no historical basis, and he rejects the conclusions both of Niebuhr and Otfried Muller respecting "this unknown and undiscoverable period." (Vol. i., p. 297.) Niebuhr's hypothesis is likewise assailed by Clinton in his *Fast. Hell.*, vol. i., p. 97. The grounds of Schwegler's condemnation, which is the most thorough-going, is as follows:—"1. The absence of any indigenous name for the Pelasgians in Italy. 2. The evident traces of Roman writers on the subject having obtained their information from the Greek logographers. 3. The contradictory accounts given by different writers of the migrations of the Pelasgians, according as they follow Hellanicus and Pherecydes or Myrsilus. 4. The absence of any historical monument of the Pelasgi in Italy, whether literary or of another kind." If unsound in his hypothesis, Niebuhr was not far wrong when he wrote the following sentence regarding this tangled question:—"The name Pelasgi is odious to the historian who hates the spurious philology out of which the pretences to knowledge on the subject of such extinct people arise." (*Hist. of Rome*, vol. i.)

In addition to the works already cited, the reader may consult Kruse's *Hellas*, vol. ii., for a copious collection of passages bearing on the Pelasgi; also the criticisms of that work by Thirlwall in the *Philological Museum*, vol. i., p. 305, and Clinton in the *Fasti Hellenici*, vol. i.; also Mommsen's *Rom. Geschichte.*

PELESTRINA, a town of Austrian Italy, in the government of Venice, stands on an island of the same name, 11 miles S. of Venice. The island is about 7 miles in length by 1 in breadth; and the town contains several churches and a town-hall. Pop. 7000.

PELEUS, the King of Phthia, and the father of Achilles, was the son of Æacus of Ægina. He was twice married. His first wife, Antigone, the daughter of Eurytion, the sovereign of the Phthians, brought him as her dowry the third part of her father's kingdom. His second wife, the Nereid Thetis, became by him the mother of the great Achilles. Peleus outlived his son.

PELEW ISLANDS, a group of small islands lying in the North Pacific Ocean, between 8. and 9. N. Lat., and 130. and 136. E. Long. They extend from S.S.W. to N.N.E., and are surrounded on all sides except the south by coral reefs. The group comprises in all about twenty islands, the largest of which, Baubelthoup, is nearly 60 miles in circumference. The islands, when seen from the sea, present a rugged and mountainous aspect. They are well covered with trees of various kinds, and the soil is in general rich. The bread-fruit tree, the cocoa-nut, banana, orange, and lemon abound, as also the sugar-cane. There is nothing that deserves the name of river on these islands; and the inhabitants derive their supplies of fresh water from small rivulets and ponds. They belong to the Malay race.

PELIGNI, The, a people of ancient Italy, inhabited the upland valley of the *Gizio*, in the heart of the Apennines, and were bounded on the N. by the Vestini, on the W. by the Marsi, on the S. by the Samnites, and on the E. by the Frentani. The character of the country they inhabited was determined by its situation. The winds from the snow-clad mountains on every side cooled the atmosphere down to the verge of severity. At the same time, the melting wreaths on the hill-sides sent down gentle streams to water and fertilize the valley. Accordingly, grapes and corn, abundant in quantity, though inferior in quality, were raised on the soil. The history of the Peligni contains no events of any very special interest. Sprung as they were from the same Sabine stock as the Marsi and Marrucini, they shared in all the important changes which befell these tribes under the dominant power of the Romans. Like them, they were defeated by Fabius in 308 B.C.; they revolted at the outbreak of the Social War in 91 B.C.; and they were ultimately included in the Fourth Region of Augustus. The principal towns of the Peligni were Corfinium, Superæquum,

and Sulmo. The last of these was the birthplace of Ovid.

PELION, a mountain in Thessaly, extending along the coast of Magnesia, and rising to the S. of Mount Ossa, with which it is joined by a low ridge. It attains to its greatest height (nearly 5000 feet) above Iolcos. Its eastern side rises precipitously from the sea, rendering the coast exceedingly dangerous, as the destruction of Xerxes' fleet can testify. It is still covered with venerable forests of oak, ash, beech, elm, and pine, as of old, when Homer gave it the epithet of εἰνοσιφυλλον, "quivering with leaves" (*Il.* ii. 632, &c.); and when its ashen spear-shafts were so famous that *Pelias* was the usual name by which the celebrated spear of Achilles was designated, and which no arm but his own could wield. The timber of which the ship "Argo" was built is likewise said to have been felled in the forests of this mountain. In the wars of the giants and the gods, the former are said to have piled Ossa upon Pelion in order to scale Olympus. The N.W. summit of Pelion is called *Plessidhi;* and the whole mountain frequently gets the name of the town *Zagora*, built on its eastern side. (See Leake's *Northern Greece.*)

PELL, JOHN, an erudite mathematician, was the son of a clergyman, and was born at Southwick in Sussex in 1610. His youth was full of high mental promise. At the school of Steyning he soon became a proficient in Latin, Greek, and Hebrew; by the age of thirteen he was ready to enter Trinity College, Cambridge; during his university course he made himself an accomplished linguist; and in 1630, the year in which he took the degree of M.A., he was holding a learned correspondence with several eminent mathematicians. This promise soon began to be fulfilled; for Pell, from this time till his death, devoted all his attention to the promotion of mathematical science. He occupied the chair of mathematics at Amsterdam from 1643 to 1646, and the same chair at Breda from 1646 to 1652. It is true that after this he was employed by Cromwell in the political office of agent to the Protestant cantons of Switzerland. It is true, also, that after the Restoration he took holy orders, and was presented by Sheldon, Bishop of London, to several rich benefices. Yet all the while the single-minded bookworm was immersed in his favourite study, publishing several works, and writing those almost innumerable letters and pamphlets which are now preserved in nearly forty folio volumes in the British Museum. He even carried his mathematical abstraction to the extent of altogether neglecting his personal affairs. His friends cozened him out of the profits of his benefices, and then left him a prey to merciless creditors. He lived in extreme indigence till his death in 1685. Dr Pell's principal works are,—*A Controversy with Longomontanus concerning the Quadrature of the Circle*, 4to, Amsterdam, 1646; *An Idea of the Mathematics*, 12mo, London, 1650; *Branker's Translation of Rhonnius' Introduction to Algebra, much altered and augmented*, 4to, London, 1668; and *A Table of Ten Thousand Square Numbers*, fol., London, 1672.

PELLA, the capital of Macedonia, was situated on a hill in the midst of an impassable marsh which was connected with the River Lydias. Its strong and secure position, and its easy communication with the sea, did not fail, in course of time, to make it a place of importance. Philip made it the metropolis of the kingdom and the seat of the royal palace. It continued to retain this dignity, and to be a prosperous city, until Macedonia was subjugated by the Romans, and ceased to be a kingdom. From that time Pella seems to have gradually declined. Its name, applied to a fountain which rises on the site of the ancient town, is almost the only record which remains of the birthplace of Alexander the Great.

PELLERIN, JOSEPH, an eminent numismatist, was born in 1684 at Marli-le-Roi, near Versailles, and received his education at Paris. His proficiency as a linguist procured for him employment in connection with the navy. At first he was engaged in the navy office in making extracts and translations from English, Spanish, and Italian. Then his merits came to be better appreciated; and the successive offices in the navy of one of the commissioners, commissioner-general, and first clerk were conferred upon him. But it was not until he had retired from public service in 1745 that the great business of Pellerin's life commenced. He then set himself to read, interpret, and classify a great variety of coins which he had collected. In doing this, it was his good fortune to light upon a plan which may be said to have given a definite form to the science of numismatics. Instead of following the arbitrary modes of preceding numismatists, he arranged his coins according to the geographical position of their countries. His system was explained and illustrated in his *Recueils de Médailles de Rois, Peuples, et Villes*, in 10 vols. 4to, Paris, 1762–78. A supplemental volume, entitled *Additions*, &c., was published shortly before his death in 1782.

PELLICO, SILVIO, an eminent Italian, celebrated for his genius and his misfortunes, was born at Saluzzo in Piedmont in 1789. His education, though irregular, was well adapted to develop his fine talents. In his father's house, which was furnished with all the luxuries of an easy fortune, his love for poetry was kindled by the sight of private theatricals. In Turin, to which the family removed about 1795, his studies were prosecuted under a clergyman. At Lyons, where he resided with a wealthy cousin for four years, he tasted all the refining pleasures which affection could suggest or money could supply. At Milan, where he settled in 1810 as a teacher of French, he devoted himself to the study of the literature of his own and of other countries. Nor was the society in which he mingled in this last city less propitious to his mental culture. Monti and Foscolo loved and cherished him. Count Porro also received him into his house as tutor to his sons, and introduced him to the celebrated men, both native and foreign, who gathered round his hospitable table. Inspired and stimulated by all these influences, Pellico set himself to enlighten and elevate his enslaved countrymen, as well as to gratify his own aspirations. In a short time his tragedy of *Francesca da Rimini* delighted all Italy with its grace and tenderness. In 1819 he was the chief agent in establishing a national periodical called *The Conciliator*. About the same time, also, he consecrated his life to the cause of Italian freedom by enrolling himself in the revolutionary society of the Carbonari. It was this activity that brought Pellico under the relentless suspicions of Austrian despotism, and entailed upon him a long and cruel persecution. Arrested in October 1820 for political offences, he was lodged in the cells of Santa Margherita at Milan. Removed to Venice soon afterwards, he lay awaiting his trial in the dreary state prison called "The Leads." His trial came on in February 1822, and resulted in a sentence of death which was commuted for a severe incarceration of fifteen years in the fortress of Spielberg, near the Moravian city of Brünn. In that distant dungeon the weary term of durance passed heavily along, inflicting pains and agonies unspeakable. At length, when it had dragged the poor prisoner almost to death's door, it was prematurely brought to a close, by the command of the emperor, on the 1st August 1830. Silvio Pellico spent his remaining years in literary pursuits at Turin. He produced the tragedy of *Ester d'Engaddi* not long after his release; *Le Mie Prigioni, Tre Nuove Tragedie*, and the tragedy of *Tommaso Moro* in 1832; and his *Opere Inedite* in 1837. He also acted as librarian to the Marchesa Barolo. His death took place on the 1st January 1854 at Moncaglieri, the villa of his patroness near Turin. Of Pellico's account of his own imprisonment, under the title of *Le Mie Prigioni*, there have been

five German translations, one English, three Spanish, and fourteen French. The narrative has charmed every reader by its unaffected and graphic story, its tender pathos, and its pervading tone of Christian faith and charity. The Life of Pellico has been written by Dumast Loménie, 1842; by Chiala, 1852; by Nollet-Fabert, 1854; and by Giorgio Briano, 1854.

PELLISSON-FONTANIER, PAUL, was born at Beziers in 1624, and after studying with success the Latin, Greek, French, Spanish, and Italian languages, he applied himself to law at Castres, and subsequently to general literature at Paris. In 1652 he purchased the post of secretary to the king; and five years afterwards became first deputy to M. Fouquet. He suffered by the disgrace of that minister; and in 1661 was confined in the Bastille, whence he was not discharged till four years afterwards. During his confinement he applied himself to the study of religious controversy; and in 1670 he abjured the Protestant religion. Louis XIV. bestowed upon him an annual pension of two thousand crowns, besides bestowing on him numerous marks of royal favour. Having taken orders, he, in 1676, received the abbey of Gimont, and some years afterwards the priory of St Orens in Auch. He died in 1693.

The best remembered work of this once popular writer is a diffuse *Histoire de l'Académie Française*, Paris, 1653. The best edition is Olivet's, Paris, 1730. He also wrote a courtly *Histoire de Louis XIV*, Paris, 3 vols, 1749; a panegyric entitled *Abrégé de la Vie d'Anne d'Autriche*, 1666; a *Histoire de la Conquête de la Franche Comté*, in 1668, given in the seventh vol. of the *Mémoires* of Father Desmolets; *Lettres Historiques et Œuvres Diverses*, Paris, 3 vols., 1749; *Recueil des Pièces Galantes*, 5 vols, 1695; *Réflexions sur les Différends de la Religion*, 4 vols., 1687, in which the author attempts a reply to Jurieu and Leibnitz on religious toleration; also an unfinished *Traité de l'Eucharistie*. Other issues of his works are *Œuvres Diverses de Pellisson*, 3 vols., Paris, 1739; and *Œuvres Choisies de Pellisson*, 2 vols., 1805. (See Bayle's *Dict.*; also De Feller's *Dict. Historique*.)

PELOPIDAS. See THEBES.

PELOPONNESUS (the modern *Morea*), a celebrated peninsula, forming one of the great general divisions of ancient Greece, was situated to the S. of Greece Proper. Owing to its peculiar form and position, it came to be regarded under several curious aspects. The old Greeks, considering it an island, and using the name of the mythical king of Pisa, called it the Isle of Pelops. Strabo and other classical writers likened it to the leaf of a vine or plane tree. On account of its natural facilities for defence, it was likewise named the Acropolis of Greece. The Peloponnesus was divided into six provinces: Arcadia in the middle, Achaia on the N., Elis on the W., Argolis on the E., and Messenia and Laconia on the S. The history and physical geography of the peninsula are given under the heads of these several states. (See also GREECE, and Leake's *Morea*. A work entitled *Peloponnesus—Notes of Study and Travel*, by W. G. Clark, M.A., appeared in London, 1858.)

PELOPS, the son of Tantalus, and grandson of Jupiter, was famous in classical fable for the singular events of his life. While still young, he was butchered, boiled, and served up at a feast which his father gave to the gods. Ceres, in a trance of melancholy abstraction, immediately fell to, and made a hearty meal on the cannibal fare. The other divinities, however, discovering the nature of the dish, shrunk from touching it, and in course of time ordered Mercury to restore the mangled body to life. Accordingly, the dead fragments were put into a cauldron. The limbs, under the action of some particular process, resumed their former positions; a shoulder of ivory was substituted for the shoulder of flesh which Ceres had eaten; and the young man came forth alive and entire. In spite of this patched-up constitution, Pelops conducted himself boldly and successfully in his after-career. Becoming a suitor for the hand of Hippodamia, the beautiful daughter of Œnomaus, king of Pisa, he agreed to prosecute his suit on the hard condition that he should either conquer the father in a chariot-race or suffer death. The contest began. By the aid of Neptune, or of Myrtilus, a treacherous servant of the king, he became the victor, and gained both the daughter and the kingdom of Œnomaus. The tomb of Pelops was preserved on the banks of the Alpheus, and a sanctuary was dedicated to him in the grove Altis at Olympia. Atreus and Thyestes were his sons. The Peloponnesus is said to have been named after him.

PELTA, a small light shield, sometimes attributed to the Amazons, but used by numerous nations of antiquity, such as the inhabitants of Thrace, Spain, and Mauritania, before its general introduction among the Greeks. It consisted mainly of a frame of wood or wickerwork covered with skin or leather, without the metallic rim, and of a great variety of shapes. It was sometimes round, as in the special case of the *cetra*, sometimes elliptical, sometimes variously sinuated round the rim, sometimes even quadrangular, but most commonly crescent-shaped or lunated, as alluded to in the "Amazonidum lunatis agmina peltis" of Virgil. (*Æneid*, i. 490.) Soldiers bearing the pelta were called *peltastæ*.

PELUSIUM (πηλος, *mud*), a frontier city of Lower Egypt, situated on the easternmost bank of the Nile, called the Ostium Pelusiacum, between the marshes of the delta and the sea. Its original distance from the Mediterranean was about 2½ miles; but, by the gradual deposition of sand along the coast-line, it is now more than double that distance inland. It was the Sin of the Hebrews (Ezek. xxx. 15), and the Peremoun or Peromi of the Copts—epithets all agreeing in origin with the Greek designation, and with the modern name *Tineh*, as "the city of ooze or mud." It was celebrated in the time of Pliny for its flax (*Linum Pelusiacum*), but its situation as the key of Egypt has gained for it a yet more noisy fame. Sennacherib and his Assyrians had their bow-strings and shield-straps gnawed in sunder by field-mice while they slept under its walls (B.C. 720–715); Cambyses, the Medo-Persian, won the crown of the Pharaohs near Pelusium, B.C. 525; the Persians re-took it, B.C. 456; it opened its gates to Alexander the Great, B.C. 333; and it was taken and retained by Antiochus Epiphanes, B.C. 173, after routing the forces of Ptolemy Philometor near its gates. The invasion of Egypt by Amrou in 618 A.D., proved the ruin of Pelusium. After making it their own, the khalifs neglected its harbours and its industry, and the city gradually disappeared from history. Its site is now marked by mounds and a few broken columns. (See the works of Champollion and Dénon *sur L'Egypte*; also, Murray's *Handbook for Egypt*, by Sir Gardner Wilkinson.)

PELWORM, an island of Denmark, 8 miles off the W. coast of Schleswig. Its area is about 15 square miles, and the soil is good, but the surface is so low that the continual efforts of the inhabitants are necessary to prevent it from being inundated by the sea. On the E. shore is the harbour of Ostersiel. Pelworm was formerly joined to the large island of Nordstrand, from which it was separated by a flood in 1634. Pop. 4000.

PEMBA, an island off the E. coast of Africa, N. of Zanzibar, S. Lat. (of the N.W. end) 4. 52., E. Long. 39. 44; length about 40 miles, breadth 10. It is low, fertile, and well wooded. Rice is extensively cultivated; and the island serves as the granary to the adjacent country. There are several creeks and indentations in the island, and an excellent harbour.

PEMBROKE, a municipal and parliamentary borough and seaport town of Pembrokeshire, South Wales, is situated on a branch of Milford Haven, 250 miles W. by N. from London, and 10 from Haverfordwest, the county town. It consists chiefly of one long irregularly-built street, ascending gradually to the castle, which stands on a bold rocky promontory. The castle is a Norman struc-

Pembrokeshire. ture of great interest, and even in its present dilapidated condition is a magnificent pile. The keep or principal tower, which is nearly perfect, is lofty and of beautiful proportions. Some remains of the walls that formerly surrounded the town are still to be seen. There are three churches, all ancient; and in the suburb of Monktown are some remains of a priory founded in 1098. There are also several dissenting places of worship, but none of the other buildings in the town require special notice. Pembroke derives its chief importance from its suburb of Pater, about 1 mile N.W. of the town, where is a government dockyard, and where a considerable trade is carried on. The borough is governed by a mayor, six aldermen, and eighteen councillors; and unites with Tenby, Milford, and Wiston in returning a member to Parliament. Market-day, Saturday. Pop. (1851) 10,107, of which Pater contains 6236.

PEMBROKESHIRE, a maritime county of Wales, occupying the extreme S.W. point of the principality. It is bounded on the N.E. by Cardiganshire, on the E. by Caermarthenshire and Caermarthen Bay, and on all other sides by the Irish Channel. The coast is very irregular in its form, and deeply indented with bays. The celebrated Milford Haven, which is in this county, penetrates with some of its minor ramifications to near its centre. The county is somewhat irregular in its general form, and is narrowest towards the northern extremity. Its greatest length from S. to N. is about 36 miles, and its greatest breadth from E. to W. is about 30 miles. It has an area of 628 square miles, or 401,691 acres, and is sixth in order of size of the Welsh counties. The Welsh name is *Sir-Benfro*, which means the promontory or headland of the country.

The northern part of the county rests upon the Cambrian group of rocks, but the southern portion lies chiefly on the old red sandstone formation, overlaid, however, in a considerable part of its extent by the carboniferous strata. The coal, which is chiefly anthracite, is but little worked. The upper beds are scooped away by shallow workings, and the produce—which is chiefly in the form of culm—is worked up with a sufficient quantity of clay to make it adhere together, and is then rolled into balls of about 4 inches in diameter. These are dried, and form the fuel of the inhabitants; so that a household fire generally seems to consist of from six to ten red-hot cannon-balls.

The mountains in this county are of no great height; but rising as they do almost from the sea-level, they present a grander appearance than they otherwise would. The principal range is that of the Precelly Mountains, in the north, of which the highest point, Precelly Top, is 1754 feet above the sea-level. The general configuration of the surface is undulating; but, with the exception of the mountains already named, the hills are nowhere high. The general want of trees, which, except in some sheltered situations, are prevented from growing above the size of mere shrubs by the south-west winds, gives a very naked and uninviting appearance to the greater part of this county; but its shores are diversified by fine headlands and well-sheltered bays, which lend a great charm to its coast scenery, and have made the neighbourhood of Tenby, one of its towns, well known as one of the most delightful of watering-places.

The rivers are of very little importance. The chief of these are the Eastern and Western Cleddau, which, rising in different parts of the county, pour their waters into two of the ramifications of Milford Haven. This celebrated haven is without doubt the most remarkable feature of the county. Its ramifications would be most aptly represented by one of the sprawling monsters so common on tea-cups. From its opening to the sea to the end of some of its branches is little short of 20 miles. In many places it is from 3 to 4 miles wide. It is completely sheltered and land-locked. The water is of great depth, and the anchorage good; and it is capable of holding the whole British navy within its recesses. It has been made famous in English history by the landing of Richard II. on his return from Ireland, where he lost his crown, and of Richmond before the defeat and death of Richard III.

The climate is moist and mild, but the south-west wind blows with the force of a tempest at times over the surface, and so affects the growth of trees that any of these which have succeeded in raising their heads above the shelter beside which they have been planted gradually assume the appearance of a pole with streamers attached, owing to the branches being projected at right angles to leeward. The soil in the southern part of the county is very fertile, and yields great crops of wheat, barley, and oats: potatoes and turnips are also largely grown. In the north the soil is poor, and the farming in a very miserable state. In the Castle Martin district, which is in the extreme south of the county, and is separated from the north by Milford Haven, there is some excellent farming; and an admirable breed of black cattle, known as "Castle Martins," is maintained. There is a considerable exportation of salted butter and pork; and the breed of horses is highly and justly prized. There is but little manufacturing industry practised.

Of late years this remote district has been thoroughly opened up by the South Wales line of railway, which, with the Great Western, affords a continuous line from London to the centre of the county; there is also a branch to Milford Haven; and attempts are now being made to connect Milford Haven with Manchester by a direct line to the north. If this project should be carried out, it is expected that Milford Haven, which at present is chiefly important as possessing one of the great government dockyards erected during the last continental war, will become one of the greatest mercantile entrepôts in the British Islands.

The principal towns are Pembroke, Haverfordwest, St David's, Tenby, Fishguard, Milford, and Narberth. The county returns one member to Parliament; Haverfordwest, with Fishguard, Narberth, and St David's, returns another; and Pembroke, with Tenby, Wiston, and Milford, returns a third. Much of the political influence was in the hands of the Owens of Orielton, but it has now passed into various hands.

A remarkable social feature in this county is the separation between the Welsh and "English," so-called, inhabitants, although these latter and their progenitors have been for many generations natives of the county. This separation has extended itself to language, customs, and even names of places; and while in the south everywhere English names, and the common English affix *ton*, are met with, in the northern parts the names of people and places are as purely Welsh as any in the principality. This peculiarity dates from a remote period, when a colony of Flemings were settled in the county.

Throughout the whole county Druidical remains are frequently met with; and in the north, near Newport, some of the most remarkable cromlechs anywhere to be met with still exist. The Coiton Arthur, one of these, on the northern slope of Precelly, is so lofty that a man on horseback may ride under the great stone or sacrificial slab, which is of such gigantic proportions as to excite feelings of wonder and curiosity as to the means which were employed to raise it to its place.

The population by the census of 1851 was 94,140, of which number 43,675 were males, and 50,465 females. This gives 149 persons to a square mile, or 4·3 acres to a person. The number of inhabited houses in 1851 was 19,136. There were 937 houses uninhabited, and 111 in course of building, giving 30 houses to a square mile, and 4·9 persons to

a house. The amount of real property assessed to the income-tax in 1851 was L.358,849, and of property assessed to the relief of the poor L.288,604. It is calculated that nearly 11 per cent. of the population live by agriculture; 9 per cent. by commerce, manufactures, &c. One-fourth of the whole are in the condition of labourers, servants, &c. Six hundred follow professions, and three thousand possess independent means.

In 1847 the total number of day-schools for the working-classes was 206, attended by 8053 scholars, of whom 49·5 per cent. were in Church of England schools. There were also 223 Sunday-schools, attended by 17,416 children, of whom only 3403 were in Church of England schools. The language is purely Welsh or purely English in the different districts of the county before referred to. (J. G—W—D.)

PENANG. See PRINCE OF WALES ISLAND.

PENARANDA-DE-BRACEMONTE, a town of Spain, in the province of Salamanca, 26 miles S.E. of the town of that name. It contains a parish church, an hospital, a Franciscan convent, court-house, prison, schools, &c. Manufactures are carried on of coarse woollen stuffs, hats, morocco leather, shoes, saddlebags, and other articles. In 1811 the Spaniards were defeated by the French at Peñaranda. Pop. 4140.

PENAS DE SAN PEDRO, a town of Spain, in the province of Albacete, 16 miles S.S.W. of the town of that name. It is surrounded with walls, and stands at the foot of a hill which is crowned by an almost impregnable fort. In the principal square stands the court-house and the prison, and in other parts of the town a parish church and schools. Chocolate, flour, soap, linen stuffs, &c., are made here; and some trade is carried on in wine, sheep, wool, &c. Pop. 7258.

PENATES, the household gods of the Romans, whether private, as relating to the family proper, or public, as relating to the family of citizens or the state. The word is derived by Freund (*Lexicon*, v. "Penates") from the root PEN, expressing the idea of entering, interior; and hence signifies properly deities of the *interior* (*penetralia*) of the house. The Lares were included among the penates with which they were not unfrequently confounded. (See LARES.) Of the former, however, a family had usually but one, whereas the penates are always spoken of in the plural, their number and names being indeed indefinite, as we learn from Varro. (Arnob. iii. 40, 123; Macrob. iii. 4.) These divinities included Jupiter, Juno, and Vesta, as the promoters of domestic union and happiness; but authorities do not always agree as to the exact divinities worshipped as penates. Their original seat is generally represented as Lavinium, whither they had been borne by Æneas from Troy. The private penates were worshipped at the hearth of every house, where a perpetual fire was kept burning in their honour, and on the table stood always the salt-cellar and the first fruits of the ground. Every meal was virtually a sacrifice to the penates. On going abroad, a prayer was offered to these divinities for a happy journey; and on returning to the hearth, the penates were saluted like the living inhabitants. A chapel to the penates of Rome stood near the centre of the city, in a place called Sub-Velia. (See Hartung, *Die Relig. der Rom.*; Smith's *Dict. of Gr. and Rom. Biog. and Myth.*; and Adam's *Roman Antiquities*.)

PENCILS. The name *pencil* is applied to a small hair brush used by artists, and also to a slender cylinder of black lead inclosed in a case, and used for drawing or writing. *Hair pencils* are made from the hair of the camel, the badger, the squirrel, the goat, and some other animals. A small bundle of hairs, with the points in one direction, is tied with strong thread at the root ends, and the points having been temporarily secured, the bundle is introduced at the wide end of a piece of quill tube, previously softened by moisture, when the thickness of the roots and of the binding thread prevents the bundle from passing quite through, while the contraction of the tube in drying holds the tuft securely. The broad end of the quill forms the socket for a holder of cedar wood. Some skill is required in tying and inserting the bundle of hair, for if pinched too tightly, the hairs spread out, instead of forming a fine point, and if not sufficiently pinched, they fall out. Hair pencils are made from the size of a crow or pigeon-quill to that of a swan. When larger pencils are required, tubes of tin-plate are used, with the stick firmly secured therein.

Lead pencils of the best kind are made of slender four-sided threads, which were formerly cut by means of a saw from solid pieces of plumbago. These threads were calcined in close vessels at a bright red heat, which imparts brilliancy and softness to the stroke of the pencil. The excellence of the mineral, as obtained from the mine of Borrowdale in Cumberland, has long given celebrity to English pencils; and the *crayons d'Angleterre* are in great esteem on the Continent. Mines of plumbago have been discovered in the United States of America, the most important of which is that at Sturbridge in Massachusetts. The mineral, however, is coarse in texture compared with that of Borrowdale. The method of preparing it is as follows:—It is pulverized, purified by sifting, and the powder is condensed into thin sheets by means of intense pressure; a welding property discovered by Mr Brockedon some years ago, and now brought into general use, owing to the threatened exhaustion of the Cumberland mine, and also for using up the waste material of the manufacture. The plan is to reduce the plumbago to a very fine powder, then to exhaust the intersticial air, and to subject the powder to the force of a hydrostatic press. In this way coherent masses are formed as dense and as useful as the original plumbago. Slices having been cut from a block thus formed: the edge of a slice is inserted in a channel in the cedar-holder, and being cut off, the process is repeated until the groove is filled; or the lead may be cut into square threads, which, after being rounded by passing through circular holes cut in pieces of ruby, are made into the proper lengths for ever-pointed pencils. The cedar for the handles is imported chiefly from South America.

The costliness of the best lead pencils has led to many attempts to economize the material by the introduction of other substances. The most successful attempt of this kind was made towards the end of the last century by a Frenchman named Conté. By mixing pure clay in various proportions with black lead in powder, and also with various coloured earths, he was able to produce pencils and crayons of various degrees of hardness and tint. The clay was carefully washed, and diffused in tubs of river-water, and after settling for two minutes, the milky liquor was drawn off by a syphon into a second tub, and the finest particles thus collected formed a soft and plastic mass fit for use after having been dried on linen filters. The powdered plumbago was calcined in a crucible to nearly a white heat, after which it was mixed with the clay in varying proportions; a fine hard pencil being produced by two parts of clay to one of plumbago, and a softer pencil by equal parts of each. The powders, when mixed, were triturated with water, and ground on a porphyry slab, and when of the proper consistence, the paste or dough was pressed into grooves in a board, previously greased, and another board was screwed down upon it; in this condition the air could act only on the ends of the pencils in the grooves, and these shrinking as they dried, the air gradually entered and dried the whole lengths. The drying was completed in an oven at a moderate heat, after which the threads were hardened by heating them in a crucible with sand or charcoal powder, the heat being regulated according to the degree of hardness required. If intended for very fine work,

such as architectural drawing, the threads were heated, and then immersed in melted wax or suet, nearly boiling hot. It was also found that different degrees of hardness could be obtained by plunging the pencils in various saline solutions, such as that of sulphate of soda, more or less concentrated. The lead thus prepared was then placed in the cedar cases in the usual way.

It has been asserted that the moderate admixture of clay with powdered plumbago takes away that unpleasant glistening property which we sometimes see in pencil-drawings, and does not diminish the blackness. By the addition of lamp-black to the clay and plumbago, pencils of every shade of black have been produced. The mixture must be calcined with exclusion of air, and afterwards made into a paste. The hardest pencils of the architect are made of lead melted with antimony and a small proportion of mercury.

The cheapest pencils are made with black lead in powder mixed with melted sulphur, and poured into holders of wood, of reeds, or of rushes. Common carpenters' pencils are made in this way. The graphitic modification of carbon deposited in the interior of coal-gas retorts is also used in the manufacture of lead-pencils. Gum-arabic, resin, sulphuret of antimony, fusible glass in powder, and other substances, are all used in making cheap pencils.

Slate pencils are made of slate for writing on slabs of the same material. Slate pencils have been made artificially by mixing slate powder with vulcanized india-rubber for writing on slabs of the same material, which are not liable to break; but the objection to the frequent handling of vulcanized india-rubber is the unpleasant smell occasioned by the sulphur. (C. T.)

PENDANT, an ornament hanging at the ear, and frequently composed of diamonds, pearls, or other jewels.

PENDANTS, in *Heraldry*, parts hanging down from the label to the number of three, four, five, or six at most, resembling the drops in the Doric frieze. When they are more than three, they must be specified in blazoning.

PENDANTS *of a Ship* are those streamers or long colours which are split and divided into two parts, ending in points, and suspended at the heads of masts, or at the yard-arm ends.

PENDLETON, a suburb of Manchester, on the slope of a hill to the N.W. of the town, consisting principally of a continuation of the main street of Salford. It contains churches belonging to various denominations, several schools, and a mechanics' institute. The inhabitants are chiefly employed in cotton-spinning, calico-printing, bleaching, and dyeing. Pop. 14,224.

PENDULUM.

THE application of the pendulum to clock-work was one of the great steps of human progress. The motion of time-keepers had previously been regulated by means of a balanced arm, which was made to vibrate backwards and forwards by the teeth of a wheel, called, from its peculiar shape, a *crown-wheel.* The time of vibration of this balance depended on the extent of its motion, and on the propelling force; and therefore clocks of this kind could hardly go with regularity; yet their performance was so satisfactory that they came into general use, and were made so small as to be portable.

Galileo, happening to observe that the oscillation of the chandelier in a cathedral was performed in the same time when the motion was dying away, as when it was extensive, was led to the idea of employing pendulums for the measurement of time. But the discovery of the true theory of isochronous vibration was made by Christian Huygens, who showed that the time of an oscillation is independent of its extent when the tendency of the body to return to its point of rest is exactly proportional to its distance from that point, and applied pendulums to regulate the motion of clocks. Now, in the case of a pendulum, the tendency to return is proportional to the sine of the arc, whereas the distance is proportional to the arc itself, and therefore the oscillations of a pendulum through large and through small arcs cannot be performed in times exactly equal to each other.

Let two bodies, A and B (fig. 1), of exactly equal weights,

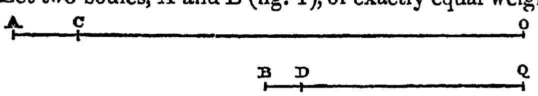

Fig. 1.

be drawn to their points of rest, O and Q, by tendencies exactly proportional to their distances from them; suppose that A is drawn twice as far from O as B is from Q, and that both are released at the same instant. The tendency of A to return is double of the tendency of B, and therefore, in some minute interval of time, when A has moved over the distance AC, B will have moved over BD, the half of AC, and will have acquired a velocity half of that of A; wherefore, at every succeeding interval of time, A must have moved twice as far as B, so that A must reach O at the very instant when B reaches Q. Proceeding on the other side of their respective points of rest, their velocities will be gradually diminished, that of A always being double that of B; and the two velocities will be extinguished simultaneously when the two bodies have reached distances equal, severally, to OA and QB. Thus it is clear that the two oscillations would go on together, and, as the same argument would hold for any other ratio of OA to QB, that the oscillations are performed in the same time, whatever may be their extents.

In order to obtain a faultless time-keeper, Huygens saw that some contrivance must be made for rendering the redressing tendency exactly proportional to the distance from the mean position. Now, the pressure required to bend a spring is proportional to the extent of flexure; and so, by attaching one end of a slender spring to the axis of the balance, the other end being fixed to the frame-work, Huygens at once brought the construction of watches to perfection as far as this part of their theory goes.

For the purpose of rendering the oscillations of a pendulum isochronous, he remarked that the tendency of a body to descend along a curve varies as the sine of the angle which the curve makes with the horizon; so that if a curve can be found such that the length of its arc, counted from the lowest point, is proportional to the sine of its obliquity, the oscillations of a heavy body describing that curve would be isochronous. Now, the cycloid, or curve described by a point in the circumference of a wheel which is rolled along a straight line, possesses this property; so that it only remained to contrive some mechanical arrangement which might produce a cycloidal motion. Huygens availed himself of the fact, that the evolute of a cycloid is another cycloid of equal dimensions. Let BOC (fig. 2) be the cycloid generated by rolling the circle of which DO is the diameter along the straight line BDC, and having produced OD to the equal distance DA, place BA and AC, two half cycloids, equal to OC and OB. Then, if a tangent be applied at any point T in the half cycloid AC, and be continued to meet OC in P, the length of the tangent TP is exactly equal to that of the cycloidal arc TC. Hence, if a plate of wood or metal be shaped into the form

ATC, and if a string fastened at A, and equal in length to AO, be partially wound upon the edge AT of the plate,

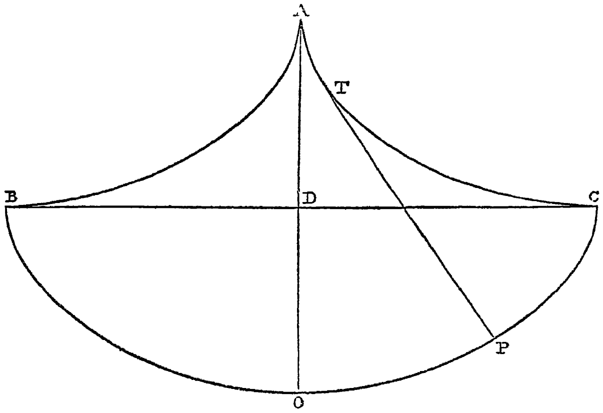

Fig. 2.

the other end P will describe the cycloidal arc OC, while another plate fitted to the curve BA will serve to produce the motion along BO.

The invention of the cycloidal pendulum has added much to the celebrity of Huygens, although it have failed to realize any practical advantages.

The difficulty of shaping the cycloidal cheeks, the loss of force caused by the bending of the flexible part of the pendulum, and, still more, the fact that the error of the ordinary pendulum is exceedingly small, have caused the cycloidal pendulum to fall into disuse; and it is now only to be found in the lecture-room as an admirable instrument for illustrating important principles.

The theory of the cycloidal pendulum has been received as complete; it is, however, defective thus far, that it can only apply to an imaginary pendulum consisting of a single heavy point, supported by a thread destitute of weight. Whenever we take into account the various motions of the parts of which any actual pendulum must be composed, the isochronism is found awanting.

Clock pendulums are now either suspended on knife-edges, or by means of thin flat springs.

The latter mode of suspension is by far the more common, because by far the better of the two. The elasticity of a steel spring is so nearly perfect that the loss of force attending its flexure and re-flexure is insignificant; nor is the oft-repeated bending found to alter its length even in many years, whereas the knife-edge is liable to a continual wear, which gradually deranges the going of the clock. Except as instruments for philosophical research, pendulums supported by knife-edges are hardly ever to be met with.

In an actual pendulum the various parts move with different velocities, whereas hitherto we have been supposing them all to move at one rate, or, which comes to the same thing, we have been assuming the whole mass of the pendulum to be accumulated at a single point, and the weight of the suspending thread to be zero. This imaginary arrangement is called the *simple pendulum*, and we must become acquainted with the manner in which such an ideal pendulum would move in order to be able to investigate the motions of a real or *compound* pendulum.

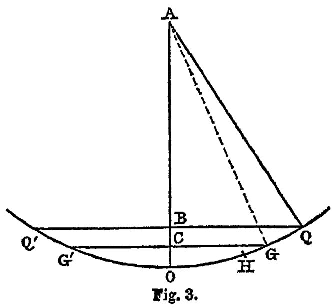

Fig. 3.

Let A (fig. 3) be the point of suspension, AG the suspending thread supposed to be devoid of weight, and G a minute heavy particle, constrained by the thread to move in the circular arc QOQ'. If the weight be brought aside to the point Q, and then let go, it will descend, gaining speed until it reach the lowest point O; then rising along the arc OQ' its velocity will gradually diminish until, at a distance OQ', equal to OQ, it become zero, when the body will begin immediately to descend again towards O. If there were no resistance from friction or from the air, this oscillation would continue for ever.

For the purpose of computing the time in which the pendulum performs its oscillation, we observe that, according to the well-known laws of mechanics, the velocity which the body acquires in descending from Q to G along the curve, is exactly equal to that which it would have acquired in falling from B to C. There is thus no difficulty in telling the velocity of the pendulum at each point of its arc; but it is by no means so easy to compute the time during which, with this ever-changing velocity, the pendulum will pass from Q to O.

If g represent the intensity of gravitation as measured by the velocity which a falling body acquires in one second of time, and if h denote the height through which the body has fallen, its velocity is given by the well known formula

$$v=\sqrt{(2gh)}\,; \quad . \quad . \quad . \quad . \quad . \quad (1.)$$

so that if h be taken for BC, the same expression gives the velocity which the pendulum has as it passes the point G.

If we put L for the length of the thread AG, A for the angle OAQ, α for OAG, we have $\mathrm{BC}=\mathrm{L}\,(\cos\alpha-\cos\mathrm{A})$, and therefore

$$v=\sqrt{(2g\mathrm{L})}\,\{\cos\alpha-\cos\mathrm{A}\}^{\frac{1}{2}}. \quad . \quad . \quad (2.)$$

Assume now some small arc GH, and the time which the heavy body would take to pass from G to H would be $\frac{\mathrm{GH}}{v}$, if its velocity did not change during that time. Actually the time must be somewhat less than this, because the velocity at H is somewhat greater than that at G; but the smaller this distance GH is taken, the less change there will be in the velocity, and therefore the more nearly will the fraction $\frac{\mathrm{GH}}{v}$ express the time occupied in passing from the one point to the other. In order to compute the whole time, we must suppose the arc QO to be divided into a great number of parts; compute the time for each, and add all these times together; and, that this computation may have any pretension to exactitude, the parts must be made very numerous. It is impossible to accomplish such a calculation without the aid of the infinitesimal method.

Let then $\delta\alpha$ represent the minute angle GAH, and δt the corresponding element of time; then, since $\mathrm{GH}=\mathrm{L}\delta\alpha$, we have

$$v=\frac{\mathrm{L}\delta\alpha}{\delta t}, \text{ and } \delta t=\sqrt{\left(\frac{\mathrm{L}}{2g}\right)}\,\{\cos\alpha-\cos\mathrm{A}\}^{-\frac{1}{2}}\,\delta\alpha, \quad (3.)$$

which gives the differential of the time, and which has to be summed or integrated in order to give the whole time.

Considerable artifice is required in order to effect the integration of this formula. Putting $\mathrm{A}=2\mathrm{B}$, $\alpha=2\beta$, whence $\cos\mathrm{A}=1-2\sin\mathrm{B}^2$, $\cos\alpha=1-2\sin\beta^2$, it becomes changed into

$$\delta t=\sqrt{\left(\frac{\mathrm{L}}{g}\right)}\,\{\sin\mathrm{B}^2-\sin\beta^2\}^{-\frac{1}{2}}\,\delta\beta \quad . \quad (4.)$$

Assume now an angle γ, such that

$$\sin\beta=\sin\mathrm{B}\,.\,\sin\gamma, \quad . \quad . \quad . \quad . \quad (5.)$$

and equation (4) becomes transformed into this one—

$$\delta t=\sqrt{\left(\frac{\mathrm{L}}{g}\right)}\,\{1-\sin\mathrm{B}^2\sin\gamma^2\}^{-\frac{1}{2}}\,\delta\gamma\,; \quad . \quad (6.)$$

or, developing by help of the binomial theorem,

$$\delta t=\sqrt{\left(\frac{L}{g}\right)}\left\{1+\tfrac{1}{2}\sin B^2 \sin \gamma^2+\tfrac{1}{2}\times\tfrac{3}{4}\sin B^4 \sin\gamma^4 + \tfrac{1}{2}\times\tfrac{3}{4}\times\tfrac{5}{6}\sin B^6 \sin\gamma^6 + \&c.\right\}\delta\gamma, \quad . \quad (7.)$$

each separate term of which can be integrated by help of the formula

$$\int \sin\gamma^n . \delta\gamma = \frac{n-1}{n}\int \sin\gamma^{n-2}\,\delta\gamma - \frac{1}{n}\sin\gamma^{n-1}\cos\gamma.$$

The result becomes, when arranged,

$$\begin{aligned} t=\sqrt{\frac{L}{g}}\Big\{ & \gamma\left[1+(\tfrac{1}{2})^2\sin B^2+(\tfrac{1}{2}.\tfrac{3}{4})^2\sin B^4+(\tfrac{1}{2}.\tfrac{3}{4}.\tfrac{5}{6})^2\sin B^6+\&c.\right] \\ & -\cos\gamma\sin\gamma\left[(\tfrac{1}{2})^2\sin B^2+(\tfrac{1}{2}.\tfrac{3}{4})^2\sin B^4+(\tfrac{1}{2}.\tfrac{3}{4}.\tfrac{5}{6})^2\sin B^6+\&c.\right] \\ & -\tfrac{2}{3}\cos\gamma\sin\gamma^3\left[(\tfrac{1}{2}.\tfrac{3}{4})^2\sin B^4+(\tfrac{1}{2}.\tfrac{3}{4}.\tfrac{5}{6})^2\sin B^6+\&c.\right] \\ & -\tfrac{2}{3}.\tfrac{4}{5}\cos\gamma\sin\gamma^5\left[(\tfrac{1}{2}.\tfrac{3}{4}.\tfrac{5}{6})^2\sin B^6+\&c.\right]+\&c.\Big\} \quad (8.) \end{aligned}$$

This complex formula gives us the interval of time during which the pendulum describes the arc OG, corresponding to the angle OAG$=2\beta$. In order to find the entire time of describing the arc OQ, we must put $\gamma=90°$, in which case β becomes equal to B; this gives cos $\gamma=$O, and

$$\tfrac{1}{2}T=\sqrt{\left(\frac{L}{g}\right)}\frac{\pi}{2}\left\{1+(\tfrac{1}{2})^2\sin B^2+(\tfrac{1}{2}.\tfrac{3}{4})^2\sin B^4+\&c.\right\};$$

or, denoting by T the whole time of a beat,

$$T=\pi\sqrt{\left(\frac{L}{g}\right)}\left\{1+(\tfrac{1}{2})^2\sin B^2+(\tfrac{1}{2}.\tfrac{3}{4})^2\sin B^4+\&c.\right\} \quad (9.)$$

for the time of passing from Q to Q′. From this the time of an oscillation can be very readily computed, since, in all practical cases, the angle B is very small.

If we imagine the extent of an oscillation to be exceedingly minute, the terms containing the powers of sin B may be neglected, and we have the usual formula

$$T=\pi\sqrt{\frac{L}{g}}, \text{ or } gT^2=\pi^2L, \quad . \quad (10.)$$

which gives the time of oscillation of an ideal pendulum, consisting of a single heavy point supported by a thread having no weight, and making oscillations imperceptible in extent.

From this equation it follows, that the lengths of simple pendulums are proportional to the squares of their times: for example, a pendulum swinging thirty times per minute must be four times as long as the common seconds pendulum, while a half-seconds pendulum must only have one-fourth part of the length.

According to observations made on moving bodies by means of Attwood's machine, the value of g comes out to be about 32 English feet, or 384 inches; wherefore the length of a simple pendulum vibrating in seconds should be

$$\frac{384}{(3{\cdot}1416)^2}=39 \text{ inches nearly.}$$

But neither observations made directly on falling bodies, nor those made by help of Attwood's machine, are susceptible of precision, while, as we shall see, measurements of the pendulum can be made with very great nicety; and thus, instead of deducing the length of the pendulum from the value of g, we derive an accurate knowledge of the intensity of gravitation from experiments made with the pendulum.

How minute soever the arc of vibration may be, the time of describing it must be longer than the result obtained from equation (10); and our first business, in attempting to deduce any accurate results from experiments made with the pendulum is, to determine the effect of the amplitude of the arc.

By help of equation (9), the following table has been computed, showing the time in which a pendulum will oscillate through arcs of 2°, 4°, 6°...up to 20°, that of making an infinitely small oscillation being taken as the unit:—

Half Arc.	Time of Oscillation.		
		1st Diff	2d Diff

20	662·60383		

The first column in each of these tables contains the half arc of vibration, or the extreme angular distance from the vertical line. The second column of the first table contains the time of an oscillation, with the first and second differences for the purpose of interpolating; and that of the second, the excess of the apparent day (or twenty-four hours as shown by the clock) over the true day (or that which would be shown by a clock of which the oscillations are imperceptible).

From these tables we see the importance of having a clock pendulum arranged to make small oscillations. If, to take an extreme example, we had a pendulum kept swinging to a distance of 20° on each side of the vertical line, and had it regulated to go to true time; and if, by the thickening of the oil, or some analogous change in the maintaining power, the oscillations were reduced to 19°, the clock would gain upon true time by 64ˢ·567, since the number of beats per day would be increased in the ratio of 1·00691 65459 : 1·00766 90258. But if, by augmenting the load on the pendulum, and, of course, properly modifying the escapement, the arc of vibration were reduced to only 1° on each side of the vertical line, and the clock again adjusted to go in true time; and thereafter, if a change in the maintaining power were to take place, so as to reduce the arc by one-twentieth part as before, the beats

of the clock would be increased in the ratio of 1·00001 72491 to 1·00001 90389, and there would be a daily gain of 0^s·154636. Thus a variation in the intensity of the maintaining power would occasion four hundred times as great an error on the pendulum with the long sweep as on that with the short one; the unsteadiness arising from this source being proportional nearly to the square of the amplitude.

"This may be confirmed by a very simple but beautiful experiment. Having suspended a leaden ball by means of a slender thread, let this simple pendulum be put in motion, so that the ball may describe a curve known to bear a considerable resemblance to the ellipse. If the times of vibration along the two axes of this curve were exactly equal to each other, the ball would repeatedly retrace the same orbit; but these times of vibration are different, and during the passage from end to end of the long axis the ball has more than returned to its position in reference to the short one, so that the axes of the orbit are gradually displaced in the direction of the movement of the ball." (*Edin. New Phil. Jour.*, vol. xv., p. 140.)

Having now investigated the law of the motion of an imaginary simple pendulum, we have to examine the case of a real one, consisting of parts, each moving with its own relative velocity. We shall first consider it as moving in a vacuum, and examine afterwards the effect of the air.

The weights of the various parts of the compound pendulum produce a tendency to turn it upon its axis, exactly equal to that which would be produced by the whole weight of the pendulum acting at its centre of gravity. But the quantity of motion existing in a moving body is greater than that which would have existed in it if all concentrated at its centre of gravity, by the motion of rotation which it would have had if turning simply with the same angular velocity on an axis passing through the centre of gravity; wherefore, in every possible case, the oscillations of a pendulum must be slower than those of a simple pendulum represented by the centre of gravity of the compound one.

If A (fig. 4) be the axis of motion supposed perpendicular to the plane of the paper, and G the centre of gravity of a compound pendulum, its motion may be represented thus: From G, with the distance GR equal to the mean distance of gyration of the mass, describe a circle; then if we suppose the whole weight of the pendulum to be distributed uniformly round the circumference of this circle, the motions of this imaginary ring will represent those of the compound pendulum.

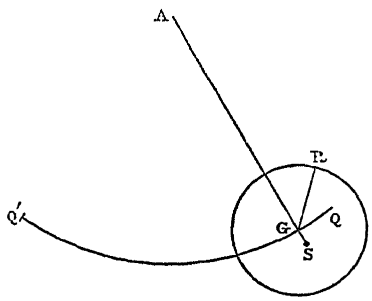

Fig 4.

When the point G is moving along the arc QGQ′, with the velocity v, the force of translation is v^2W, W being the whole weight of the pendulum; but the velocity of rotation of the ring R is $v\frac{\text{GR}}{\text{AG}}$, or, symbolically, $v\frac{\text{R}}{l}$, putting GR = R, AG = l; wherefore the rotatory motion is

$$v^2\frac{\text{R}^2}{l^2}\text{W};$$

and therefore the whole motion existing in the moving mass is

$$\text{W}v^2\frac{l^2+\text{R}^2}{l^2}=\text{F}. \quad . \quad . \quad . \quad (11.)$$

Now the total quantity of motion in any system, as measured by combining the weight of each part with the square of its velocity, is proportional to the quantity of *work* which has produced that motion, the work being estimated by combining each pressure with the distance through which it has acted, so that in any system whatever

$$2g\,.\,\text{work} = \text{motion}.$$

But the pressure in this case is W, and the distance through which it has acted is l (cos α − cos A); so that Wl (cos α − cos A) represents the quantity of work expended in producing the motion F. Wherefore

$$2g\ \text{W}l(\cos\alpha-\cos\text{A})=\text{W}v^2\frac{l^2+\text{R}^2}{l^2}; \quad (12.)$$

or, putting for v its equivalent $l\frac{\delta\alpha}{\delta t}$,

$$\delta t=\sqrt{\left(\frac{l+\frac{\text{R}^2}{l}}{2g}\right)}\{\cos\alpha-\cos\text{A}\}^{-\frac{1}{2}}\delta\alpha. \quad . \quad (12.)$$

If, then, we make GS a third proportional to AG and GR, and put AS = L, or

$$\text{L}=l+\frac{\text{R}^2}{l}, \quad . \quad . \quad . \quad . \quad . \quad (13.)$$

we shall have

$$\delta t=\sqrt{\left(\frac{\text{L}}{2g}\right)}\{\cos\alpha-\cos\text{A}\}^{-\frac{1}{2}}\delta\alpha,$$

which is an exact copy of equation (3); and therefore we conclude that the compound pendulum, of which GR is the mean distance of gyration, will oscillate in exactly the same time as a simple pendulum of which the length is AS.

From this equation (12) it appears that the oscillations of a compound are similar to those of a simple pendulum, and that therefore the tables which we have given apply to actual clocks.

But the investigation also shows clearly that the oscillations of a compound cycloidal pendulum cannot be isochronous; for when the pendulum is at the middle, the quantity of motion is augmented in the ratio of AO² + R² : AO², whereas, when the pendulum is in the direction TP, the augmentation is in the ratio of TP² + R² : TP², which is a higher ratio; so that this circumstance ought to be taken into account when we investigate the isochronism of a compound pendulum.

The point S is called the centre of oscillation, or that point at which, if the whole mass of the pendulum were supposed to be concentrated, the time of oscillation would not be changed; and we have this property, that *the rectangle under the distances of the point of suspension, and of the centre of oscillation from the centre of gravity, is equivalent to the square of the mean distance of gyration*, and is therefore constant for the same pendulum; that is AG . GS = GR².

From this law Huygens concluded that the point of suspension and the centre of oscillation are interchangeable; in other words, if the pendulum were suspended on an axis passing through the point S, its time of oscillation would be the same as when suspended from A.

Captain Kater proposed to utilize this property by employing it to determine the exact length of a simple pendulum vibrating in the same time with a compound one. For this purpose he placed two knife-edges exactly parallel to each other, one at A, the other at S, and carefully adjusted the weights of the parts by repeated trials, until he found that the two times of oscillation were alike; then, measuring the distance between the two knife-edges, he obtained the length of the corresponding simple pendulum; from which the intensity of gravitation can be computed.

This beautiful process is the only one available for determining with great nicety the length of the seconds pendulum, since it avoids the difficult and unsatisfactory operation of measuring with great precision the dimensions of the various parts; it is, however, subject to several sources of

minute error, which have either to be guarded against or allowed for.

The first of these sources of error is the wearing of the knife-edges, which gradually changes the points of suspension, and renders a new adjustment necessary; and it is a very important question, whether the distance between two blunted knife-edges on which the oscillations are performed in equal times be truly the length of the corresponding simple pendulum. M. Laplace demonstrated that the blunting of the edges does not impair the accuracy of the convertible pendulum.

For the purpose of examining thoroughly into this matter, let the pendulum be suspended on a cylinder, of which the axis is A (fig. 5), and the radius AM $=\rho$; this cylinder rolling upon a horizontal plane KL. In this arrangement the point G must describe a convoluted cycloid, while A moves in a horizontal line.

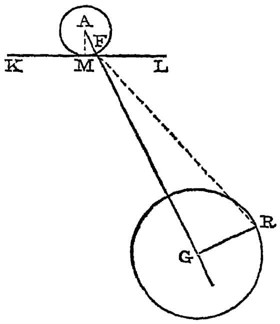

Fig. 5.

The linear motion of the point G is composed of two motions, one perpendicular and proportional to AG, represented by $l\,.\,\delta\alpha$, and the other horizontally, on account of the motion of the centre A, represented by $\rho\,.\,\delta\alpha$. The angle of these two motions being α, it follows that the square of the actual linear motion of G is $(l^2-2l\rho\cos\alpha+\rho^2)\,\delta\alpha^2$; wherefore the motion of translation is

$$W\{l^2-2l\rho\cos\alpha+\rho^2\}\left(\frac{\delta\alpha}{\delta t}\right)^2$$

and the entire quantity of motion in the system

$$W\{l^2-2l\rho\cos\alpha+\rho^2+R^2\}\left(\frac{\delta\alpha}{\delta t}\right)^2;$$

while the descent of the centre of gravity is as before, $l(\cos A-\cos\alpha)$, so that the equation of motion becomes, putting, as before, $A=2B$, $\alpha=2\beta$,

$$\delta t=\sqrt{\left(\frac{1}{gl}\right)}\left\{\frac{(l-\rho)^2+R^2+4l\rho\sin\beta^2}{\sin B^2-\sin\beta^2}\right\}^{\frac{1}{2}}\delta\beta;$$

or, making $\sin\beta=\sin B\,.\,\sin\gamma$, and putting, for shortness sake,

$$\frac{4l\rho}{(l-\rho)^2+R^2}=k$$

$$\delta t=\sqrt{\left(\frac{(l-\rho)^2+R^2}{gl}\right)}\left\{\frac{1+k\sin B^2\sin\gamma^2}{1-\sin B^2\sin\gamma^2}\right\}^{\frac{1}{2}}\delta\gamma. \quad (14.)$$

Expanding the variable part of this expression according to the powers of $\sin\gamma^2$, integrating each term, and taking the integral between the limits $\gamma=-\frac{\pi}{2}$, $\gamma=\frac{\pi}{2}$, we have for the time of an oscillation—

$$\begin{aligned}T=\pi\sqrt{\frac{(l-\rho)^2+R^2}{gl}}\Big\{&1+(\tfrac{1}{2})^2\sin B^2\,[1+\tfrac{2}{1}\cdot\tfrac{1}{2}k]\\&+(\tfrac{1}{2}\cdot\tfrac{3}{4})^2\sin B^4\,[1+\tfrac{4}{3}\times\tfrac{1}{2}k-\tfrac{2}{1}\cdot\tfrac{4}{3}\times\tfrac{1}{2}\cdot\tfrac{1}{4}k^2]\\&+(\tfrac{1}{2}\cdot\tfrac{3}{4}\cdot\tfrac{5}{6})^2\sin B^6\,[1+\tfrac{6}{5}\times\tfrac{1}{2}k-\tfrac{4}{3}\cdot\tfrac{6}{5}\times\tfrac{1}{2}\cdot\tfrac{1}{4}k^2+\tfrac{2}{1}\cdot\tfrac{4}{3}\cdot\tfrac{6}{5}\\&\qquad\times\tfrac{1}{2}\cdot\tfrac{1}{4}\cdot\tfrac{3}{6}k^3]\\&+(\tfrac{1}{2}\cdot\tfrac{3}{4}\cdot\tfrac{5}{6}\cdot\tfrac{7}{8})^2\sin B^8\,[1+\tfrac{8}{7}\times\tfrac{1}{2}k-\tfrac{6}{5}\cdot\tfrac{8}{7}\times\tfrac{1}{2}\cdot\tfrac{1}{4}k^2+\tfrac{4}{3}\cdot\tfrac{6}{5}\cdot\tfrac{8}{7}\\&\qquad+\tfrac{1}{2}\cdot\tfrac{1}{4}\cdot\tfrac{3}{6}k^3-\&c.]+\&c.\Big\}\quad . \; . \; . \quad (15.)\end{aligned}$$

the law of progression of which is obvious.

This formula gives the time of oscillation of a pendulum suspended on a cylinder, without any restriction as to the radius of curvature. From it we see that the correction for amplitude is not the same as for a pendulum hung by a perfect knife-edge, and that therefore the motions of no simple pendulum can strictly represent those of this one.

When the value of k is small,—that is to say, when AM is minute in comparison with AG, and when the angle B also is very small,—the expression becomes

$$T=\text{nearly }\pi\sqrt{\left\{\frac{l-2\rho+\frac{R^2}{l}}{g}\right\}}\{1+\tfrac{1}{4}\sin B^2(1+k)\}$$

and, if the oscillations be supposed to be infinitesimally minute,

$$(T)=\pi\sqrt{\left\{\frac{l-2\rho+\frac{R^2+\rho^2}{l}}{g}\right\}}\quad . \; . \quad (16.)$$

which agrees with those of a simple pendulum of which the length is

$$L=l+\frac{R^2+\rho^2}{l}-2\rho. \quad . \; . \; . \; . \quad (17.)$$

If, then, it were proposed to place the cylinder A at such a distance from the centre of gravity as that the time of a minute oscillation may be equal to that of a simple pendulum having the length L, we should have to solve the quadratic equation—

$$l^2-(L+2\rho)l+R^2+\rho^2=0.$$

Now, according to the properties of such equations, if l and λ be the two roots, their sum must be $L+2\rho$, and their product $R^2+\rho^2$, or

$$l+\lambda=L+2\rho\,;\ l\lambda=R^2+\rho^2. \quad . \; . \quad (18.)$$

Now $l+\lambda$ represents the distance between the centres of two cylinders placed on opposite sides of the centre of gravity; and thus, since

$$l+\lambda-2\rho=L,$$

the distance between the surfaces of the cylinders is equal to the length of the corresponding simple pendulum.

This investigation is free from all limitations as to the magnitude of the cylinders; so that if carefully-turned and polished cylinders were substituted for the knife-edges, and if the corrections for the amplitudes of the arcs of vibration were made according to the formula (15), the results would be rigorously exact.

When the curvatures of the two edges are not alike, an error is introduced, because the one distance is then the major root of the equation

$$l^2-(L+2\rho)\,l+R^2+\rho^2=0.$$

while the other is the minor root of another equation

$$l^2-(L+2\rho')\,l+R^2+\rho'^2=0.$$

The sum of these roots, when ρ and ρ' are minute, approaches sensibly to

$$l+\rho+\rho'\,;$$

so that in practical cases the fact of the edges being blunted does not vitiate the results.

The next source of error which we shall consider is the buoyancy of the air in which the experiments are made.

If the pendulum were composed entirely of one kind of material, its centre of gravity would coincide with the centre of buoyancy, and the co-efficient W in the first member of equation (12) would have to be replaced by W − A, A being the weight of the displaced air. But when the pendulum is made of various materials, the inquiry becomes a little more difficult. It will be enough to consider those cases in which the centre of buoyancy, the centre of gravity, and the points of suspension, lie all in one straight line. Let then B (fig. 6) be the centre of buoyancy, its distance from G being represented by e; then the motion which the system has acquired being due to the descent of the weight W through the distance l $(\cos\alpha-\cos A)$ less that of A through $(l-e)$ $(\cos\alpha-\cos A)$, we must have

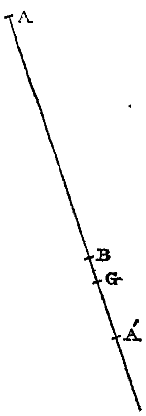

Fig. 6.

$$2g\{(W-A)\,l+Ae\}\,(\cos\alpha-\cos A)$$
$$=W(l^2+R^2)\left(\frac{\delta\alpha}{\delta t}\right)^2;$$

wherefore the length of a corresponding simple pendulum vibrating in vacuo is

$$L=\frac{W\,(l^2+R^2)}{(W-A)\,l+Ae}. \quad . \quad . \quad . \quad (19.)$$

If then we desire to place A so that the oscillations may agree with those of the simple pendulum L, we must solve the quadratic equation

$$l^2-\left(1-\frac{A}{W}\right)Ll+R^2-\frac{A}{W}Le=0. \quad . \quad (20.)$$

The two roots of this equation will not represent the one GA on the one side and the other GA′ on the other side of the centre of gravity, but two distances on one side, either of which will satisfy the condition of oscillation. When the pendulum is inverted to be suspended from the point A′, the equation becomes, putting λ for GA′,

$$\lambda^2-\left(1-\frac{A}{W}\right)L\lambda+R^2+\frac{A}{W}Le=0. \quad . \quad (21.)$$

The major root of the one and the minor root of the other being taken, we have the proper values of l and λ, viz.,—

$$l=\frac{W-A}{2W}L\pm\sqrt{\left\{\left(\frac{W-A}{2W}L\right)^2-R^2+\frac{A}{W}Le\right\}}$$
$$\lambda=\frac{W-A}{2W}L\mp\sqrt{\left\{\left(\frac{W-A}{2W}L\right)^2-R^2-\frac{A}{W}Le\right\}}$$

the sum of which is no longer independent of the specialities of construction of the pendulum.

If the centre of buoyancy coincide with the centre of gravity, e becomes zero, and

$$l+\lambda=\frac{W-A}{W}L; \quad . \quad . \quad . \quad . \quad (22.)$$

from which the length of the simple pendulum can be easily deduced; but *in no other case can the reversible pendulum vibrating in air give a result dependent only on the measurement of the distance between the knife-edges.*

While the air modifies the vibrations of a pendulum by its buoyancy, it also influences them by its resistance to motion. The law of this resistance, like all the laws connected with the motion of fluid bodies, is very imperfectly known; no method of analysis has been discovered which can at all approach the difficulties of the subject; nor has any glimpse yet been obtained of the internal arrangement of the parts of fluids, so that we have not even a foundation on which to build a train of reasoning.

The resistance which the air presents to a moving body is usually supposed to be proportional to the square of the velocity, and also, with similar solids, to the extent of surface; but there is some reason to believe that both proportions are only approximate. Even when assisted by this supposition, the powers of the higher calculus fail in discovering what effect this resistance has on the going of a clock. The equation of motion, when expressed in the notation of Leibnitz, takes the form

$$\frac{\delta^2\alpha}{\delta t^2}=P\sin\alpha-Q\left(\frac{\delta\alpha}{\delta t}\right)^2$$

which is not integrable by any known process.

Attempts have been made to overcome this difficulty by assuming that the resistance is exceedingly small in comparison with the tendency of the pendulum to descend along the arc; and it has been shown that, in this case, the extent, but not the time, of an oscillation is sensibly affected. Yet all such demonstrations want conclusiveness, since the result extracted may be only a disguised form of that assumption which has been arbitrarily made in order to bring the matter apparently within the power of the calculus.

Although we cannot ascertain the precise effects of the air's resistance, we may, by a general view of the subject, arrive at some useful conclusions.

On comparing the motion of a pendulum describing a large arc QQ′ (fig. 7), with that of another of the same dimensions oscillating through the smaller arc qq', we perceive that, generally speaking, the velocities of the two are proportional to the lengths of the arcs; wherefore the intensities of the air's resistance must be nearly proportional to the squares of those lengths. Now, the redressing tendencies are proportional to the sines of the arcs; wherefore it follows that the air's resistance bears a less proportion to the redressing tendency in the case of the small arc than in that of the large one, which forms another argument in favour of a small arc of vibration.

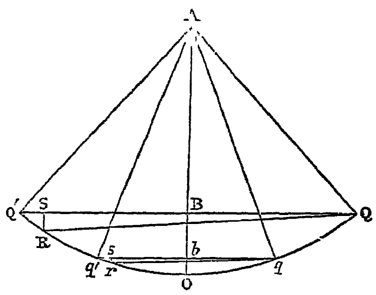

Fig. 7.

While the intensity of the resistance is proportional to the square of the length of the arc, the distance through which it acts is proportional to that length, wherefore the quantity of motion destroyed, or the loss of force, is proportional to the cube of the length. Now, if the pendulum, after having been dropped from Q, rise only on the other side to the distance OR, the loss of force is proportional to the distance SR, by which R is lower than Q; and therefore, we have, approximately

$$SR : sr :: QR^3 : qr^3.$$

Again, if we assume that the arcs Q′R, qr, are so small as to be undistinguishable from their tangents, the trigons Q′SR, $q'sr$ are similar to Q′BA, $q'ba$; so that if the arcs OQ, oq themselves be small,

$$Q'R : q'r :: OQ^2 : oq^2$$

approximately.

If, then, the oscillations of a pendulum be slowly arrested by the air's resistance alone, the successive amplitudes must form a progression in which the differences are proportional to the squares of the terms; that is, they must form a harmonic series, and the number of beats occurring between the amplitudes OQ = A and $oq=\alpha$, must be proportional to the difference of the inverse powers of α and A, or to $\frac{1}{\alpha}-\frac{1}{A}$. It has been erroneously asserted that the arcs should form a decreasing geometrical progression. In virtue merely of the air's resistance, then, the pendulum would never be brought absolutely to rest.

In addition to this resistance there is the friction on the knife-edge, which is nearly constant. When the pendulum is inclined at the angle α, its pressure upon the support is $W\,.\,\cos\alpha$, and therefore if f be the coefficient of friction for the particular knife-edge, the redressing tendency is $W(\sin\alpha-f\cos\alpha)$; and if we put $f=\tan\phi$, ϕ being then the angle of repose, or the minute angle through which the pendulum may be drawn aside from the vertical position without tending to return, the redressing tendency becomes

$$\frac{W}{\cos\phi}(\cos\phi\sin\alpha-\sin\phi\cos\alpha)=W\sec\phi\,.\,\sin(\alpha-\phi).$$

From this it is apparent that each oscillation will be performed on either side of a line inclined to the vertical line by the angle ϕ, so that the amplitude of the oscillations will form a decreasing arithmetical progression, of which the common difference is $2\,\phi$.

From the same expression it follows, that the time of an oscillation will be reduced in the ratio of $\sqrt{\cos\phi}$ to 1; or that, in order to make it vibrate in true time, the pendulum must be lengthened in the ratio of sec ϕ to unit.

In all practical cases, however, the angle ϕ is exceedingly minute, so that its cosine and secant cannot differ from the radius by any appreciable quantity; in other words, we may hold that the friction on the knife-edge has no perceptible influence on the time-keeping.

When both the air's resistance and the friction act together, the amplitudes must form a complex progression, approaching more and more nearly to an arithmetical one as the arcs become shorter.

A more serious cause of error in the determination of the length of the pendulum, is to be found in the yieldingness of the support. In our investigations, the point of suspension has been supposed to be absolutely immoveable; but there is no substance which does not yield to the pressure applied to it, and therefore, as the pendulum swings from side to side, the point of suspension oscillates also; and the whole framework becomes truly a part of the vibrating mass.

Hence the propriety of securing the suspending plate to a strong wall; and hence also the impropriety of the too common practice of making the house-clock rest on the bottom of its case.

When a pressure is applied to some point in an elastic structure, the form of the structure is deranged, and the point to which the pressure is applied is displaced; but the displacement is not necessarily in the direction of the pressure. Every elastic structure has, in reference to any given point in it, three directions at right angles to each other, in one of which the flexibility is a maximum, in a second a minimum, and in the third a maximum or minimum. And it is only when the pressure is applied in one of these three directions that the displacement is in the direction of the pressure. Hence, a general inquiry into the effect which the flexibility of the support may have upon the motion of the pendulum would be excessively complicated. In order to simplify it, we shall assume that the three directions alluded to are one vertical, one horizontal in the plane of the oscillation, and the third also horizontal, but perpendicular to the plane of oscillation; and this supposition is admissible, because of the symmetry of the parts.

The pressure, W cos α, which the knife-edge exerts against the suspending plate may be decomposed into two pressures, W cos α^2 in a vertical, and W cos α sin α in a horizontal direction; so that if μ and m be the coefficients of flexibility in those two directions, μW cos α^2 will be the depression, and mW cos α sin α the horizontal displacement of the point of suspension in virtue of this pressure.

But the point of suspension does not take up truly the position indicated by these quantities, because the matter of the framework has to be moved; and the motion imparted to it forms part of the sum total. Yet, as the quantity of motion is measured by combining the square of the velocity with the mass, and as the whole displacement is microscopical, the quantity of motion in the framework must be excessively minute, and we may assume that the above expressions represent truly the position of the support corresponding to the inclination α.

The differentials of these are

$$\mu W \sin 2\alpha \,.\, \delta\alpha, \text{ and } mW \cos 2\alpha \,.\, \delta\alpha;$$

wherefore the motion of the centre of gravity of the pendulum is composed of three motions,—$l\delta\alpha$ at an inclination of α to the horizon, μW sin 2α . $\delta\alpha$ upwards, and mW cos 2α . $\delta\alpha$ horizontally outwards; so that the square of its actual motion is, neglecting those terms which contain the squares of m and μ,

$$\{l^2 + 2lW\,(m \cos\alpha \,.\, \cos 2\alpha + \mu \sin\alpha \,.\, \sin 2\alpha)\}\,\delta\alpha^2;$$

and therefore the differential equation of motion is

$$\delta t = \left\{ \frac{R^2 + l^2 + 2lW\,(m\cos\alpha \,.\, \cos 2\alpha + \mu \sin\alpha \,.\, \sin 2\alpha}{2gl\,(\cos\alpha - \cos A)} \right\} \delta\alpha$$

and the integration of this expression would give the value of the time t.

When the arc of vibration is minute, the length of a simple pendulum vibrating in the same time becomes

$$L = \frac{R^2 + l^2 + 2lmW}{l};$$

and therefore, if we wish to determine that value of l which will produce a given time of oscillation, we must resolve the quadratic equation

$$l^2 - (L - 2mW)\, l + R^2 = 0.$$

Now, if l and λ be the two roots of this equation, we must have

$$l + \lambda = L - 2mW;$$

and thus the distance between the knife-edges of a reversible pendulum is less than the true length of the simple pendulum by $2m$W, m being a coefficient depending on the flexibility of the supports.

This equation suggests a method of discovering the amount of this inaccuracy; for if two pendulums of different weights be swung in succession from the same support, the values of L deduced from them will differ by the quantity $2m\,(W - W')$, and that difference will give the value of the coefficient m.

We have all along supposed the parts of the pendulum to be perfectly rigid, and have now to inquire whether the flexibility of the rod be not another source of error. This part of the subject has not received an adequate share of attention; and, indeed, the method employed by Borda for determining the length of the pendulum seems to have been contrived in neglect of the errors occasioned by the flexibility of the parts.

In order to put this matter in a clear light, let us construct a pendulum AXY (fig. 8), composed of a fine inflexible line carrying weights X, Y, &c., at various distances, AS being the length of the corresponding simple pendulum. Then, as this system oscillates, the changes in the motion of a particle placed at S are exactly those which gravitation would induce on that particle if suspended separately from the point A; the whole of its tendency to descend along the arc is expended in accelerating or retarding its motion. But it is different with a particle placed at X, above S: the actual motions of this particle are less rapid than they would have been if it were attached to A by a separate thread, in the ratio of AX to AS; and therefore only a part of the weight X, represented by $X \,.\, \frac{AX}{AS}$, is employed in accelerating or retarding its motion, the remainder $X \,.\, \frac{XS}{AS}$ being resisted by the stiffness of the pendulum-rod. That is to say, the body X tends to bend the pendulum-rod inwards by a pressure $X \,.\, \frac{XS}{AS} \sin\alpha$.

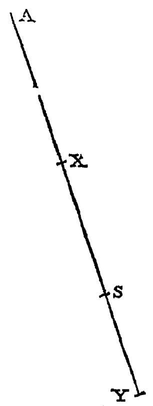

Fig. 8

In the same way, a body placed at Y, below S, has its motions made more rapid than they would have been if it were separately suspended, and therefore it presses outwards on the rod with an intensity of $Y \,.\, \frac{YS}{AS} \sin\alpha$.

It thus seems that the structure of the pendulum is subjected to variable internal strains, caused by the motions of

its own parts, and that, unless it be so strong as to resist these strains without any appreciable change of form, its oscillations cannot agree with those which have been deduced on the supposition of perfect rigidity.

Borda's method of determining the actual length of the seconds pendulum was to suspend a ball of platinum by a fine wire (fig. 9), to measure the entire length from the knife-edge to the lowest point of the ball, and thence to compute, by help of the measured dimensions of the apparatus, the mean distance of oscillation. In order to avoid the necessity of measuring the dimensions of the knife-edge and its framework, Borda first adjusted these parts separately to oscillate in the intended time, in order that they might exert no perceptible influence on the motion of the ball. By this ingenious device, the calculations were much simplified, as only the dimensions of the ball, the suspending cap, and the wire, had to be taken into account. But the whole arrangement is liable to the objection, that the centre of the ball, the point of attachment, and the knife-edge, do not remain in one straight line during the oscillation. A body suspended in this way has two kinds of motion, which may exist separately or conjoined. One of these is a short-period vibration, in which the centre of gravity remains nearly at rest; the other is a swinging motion, composed of two isochronous oscillations,—one of the wire on the knife-edge, the other of the ball on the point of attachment. The nature of this complex motion has not been investigated: it indeed presents difficulties of a very high order; and until these difficulties be overcome, a degree of uncertainty must attach to all observations made with this kind of pendulum.

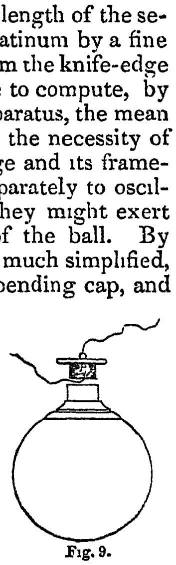

Fig. 9.

Besides being flexible, the pendulum-rod is distensible. Now, when suspended from the point A, the parts are subjected to one set of strains; when suspended from S, to another. Unless, then, the rod be of such strength as to resist these changes of strain without any appreciable change of length, the measurement of the distance between the knife-edges must give a result perceptibly erroneous.

These sources of error in the use of the convertible pendulum are inevitable; there are others to be found in the imperfections of the workmanship.

It is essential to have the plate on which the knife-edge rests perfectly flat and accurately horizontal. The sustaining plate is usually made of agate; yet there are few minerals capable of taking a high polish and so ill adapted for the purpose. The agate consists of layers of various degrees of hardness; and when it is ground with emery upon a brass surface, the hard parts are seen to project, somewhat like the layers of planed pine-wood. On this account, it is exceedingly difficult to obtain a surface on agate truly flat. This substance has another bad quality,—that its structure is porous, and that contact with it rapidly impairs a steel edge. A surface worked in rock-crystal or Cairngorm topaz would be much preferable. The want of flatness in the agate plate may account for the displacement of the knife-edge which has sometimes been noticed.

The two knife-edges must be placed exactly parallel to each other, and their plane must pass through the centre of gravity of the mass. In the accounts of experiments made with the convertible pendulum, there is no notice of any precautions which have been taken for the purpose of securing the fulfilment of these conditions; they seem to have been left entirely to the care of the workmen. It is not enough that, when one knife-edge is horizontal, and the pendulum at rest, the other knife-edge also be horizontal; it is of great importance that both be in the same vertical plane.

Every body has three principal axes passing through the centre of gravity at right angles to each other, on which its motion of rotation, with a given angular velocity, is maximum or minimum; and the amount of rotation on any other axis varies according to its position in reference to these three. On account of the symmetry of the parts in all actual cases, one of the principal axes may be assumed as lying along the length of the pendulum; one of the other two being in the plane of oscillation, the third at right angles to it.

The *bob*, or heavy part of the pendulum, is sometimes made flat or lenticular, the rod and other parts partaking of the same shape. In such case, the amount of rotation on the axis parallel to the knife-edge is greater than on that perpendicular to it, and any twist on the pendulum-rod causes the rate of the clock to vary: and, particularly when the rod is of wood, this form of *bob* causes great irregularity. In order to avoid this source of error, and to render innocuous any deviations of the knife-edges in azimuth, the mass of the pendulum should be distributed uniformly round its vertical axis, so as to render the amount of rotation constant for every horizontal axis passing through the centre of gravity.

The convertible pendulum is not kept in motion by machinery, like the pendulum of a clock, but having been set in motion, is allowed gradually to come to rest; and as it continues to oscillate for but a short while, the number of oscillations which it would make per day has to be ascertained by comparing its movements with those of a clock pendulum of which the rate is known.

In order to make this comparison, the convertible pendulum is erected in front of the clock, a telescope of low power being fixed at a little distance. A distinct white mark is made on the clock pendulum, of size sufficient to be just hid from view by a part of the convertible pendulum when both are at rest. If now the two pendulums were to oscillate in the same direction, keeping true time with each other, the white mark would be always concealed; but if, as is purposely arranged, the one pendulum oscillate a little more slowly than the other, they will gradually separate from each other, and the white mark will become visible. As the separation increases to become one beat, the pendulums pass each other in different directions, and the mark is covered for too short a time to prevent its being visible; but as the difference approaches to be two beats, the motions again agree, and the spot is hid. Thus, by noticing the successive instants of the complete disappearance of the mark, the observer can discover the difference between the rates of the two pendulums with great precision.

On account, however, of the diminution of the amplitude, the rate of the free pendulum slowly accelerates; and thus the intervals between the successive disappearances are unequal. Besides this, the vèlocities at the middles of the arcs become different, and the disappearance is not complete; the most favourable time for observation being when the apparent velocities of the parts, as seen from the telescope, are exactly equal to each other. It is thus a matter of very considerable difficulty to determine with precision the ratio of the beat of the free pendulum to that of the clock; and, in addition, there is the error to which the rate of the clock itself is subject.

Besides all these sources of minute error, which are special to the subject, there is that which attends all attempts at minute measurement, and which arises from thermal expansion. The comparison of the distance between the two knife-edges with the divisions on a standard scale, at a given temperature, requires an accurate knowledge of the rates of expansion of the two rods, and during the motion of the pendulum an account must be taken of the temperature. Now, the thermometer only can give the temperature

of the surrounding air, which only agrees with that of the pendulum when the changes are very slow; and therefore it is of the utmost importance, for the exactitude of the conclusions, that all experiments be carried on in a place not liable to fluctuations of temperature.

On reviewing all these sources of error, we need not be surprised to find disagreements among the results obtained by different observers, particularly when we consider that the expressions for the lengths of the pendulum have been carried to the ninth decimal place, that for the *thousand-millionth* part of a metre. It is matter of astonishment to find the results agree so well.

The determination of the length of the pendulum in different latitudes throws a great light upon certain departments of physical astronomy; and it is this circumstance which gives importance to the present subject. Among the experiments which have been recorded, there are many close coincidences, and not a few discrepancies, in the last-place figures. From these latter, attempts have been made to estimate irregularities in the structure of the earth; while from the former the amount of its oblateness is inferred. In this way, the pendulum becomes an important and valuable instrument for astronomical research.

For the purpose of discovering the variation of gravity at different parts of the earth's surface, it is sufficient to compare the number of oscillations which a pendulum makes per day at one place with the number which the same pendulum makes at another place: the intensities of gravitation at the two places are inversely as the square of these numbers.

Whichever of these two pendulums may be used, the trustworthiness of the result depends mainly upon the means which are taken to compare the oscillations with the length of the day. Though it be customary to use the mean solar day as the standard, the comparisons are really made with the sidereal day, that interval of time being, of all others, the most susceptible of exact and ready measurement. Now, with a four-foot portable transit instrument, the instant of the passage of a star over the meridian can hardly be determined to within one-tenth part of a second, the distance passed over by the image of an equatorial star in that time being little more than the three-thousandth of an inch upon the wires, and the position of the instrument being liable to errors of collimation, of levelling, and of azimuth. We cannot therefore venture to say that the clock's rate in a given day can be determined certainly to within one-tenth part of a second, although the comparisons have been made at an interval of twenty-four hours. Seeing, then, that the free pendulum is compared with the clock only over a small fraction of the day, it is a great deal to expect that its daily rate can be ascertained to within one second of time.

A change of one second per day in the rate of a clock corresponds to a change of $\frac{1}{43200}$th in the length of the pendulum, which is about $\frac{1}{1100}$th of an inch, or $\frac{1}{43}$d of a millimetre; and therefore we may regard this distance as indicating the probable limit of exactitude.

From careful measurements made at the instance of the British government, the length of the seconds pendulum at London, and at the level of the sea, is 39·1393 inches; while the length of the decimal pendulum, obtained at Paris with equal care, is ·7419076 metre. Now, by discussions on measurements made at various places, the length of the pendulum is found to be

$$1 - \cdot 00275 \cos 2 \text{ lat.},$$

according to some, and

$$1 - \cdot 00268 \cos 2 \text{ lat.},$$

according to other investigators; and therefore we may assume, with Vince, that

$$1 - \cdot 00270 \cos 2 \text{ lat.}$$

represents the length of the pendulum at any latitude, when the pendulum at latitude 45° is taken as the unit.

According to this formula, the pendulums at Paris and London should be in the ratio of 1·000360 to 1·000605. Multiplying the length of the decimal pendulum by the square of the fraction $\frac{1000}{864}$, we obtain ·9938534 for the length of the common seconds pendulum at Paris, and augmenting this in the above ratio, ·9940967 metre for the length of the pendulum at London; wherefore the ratio of the metre to the inch, as determined by help of the pendulum, is 39·1393 to ·9940967, from which the length of the metre comes out 39·37172 inches. Direct comparison has given 39·37079, and there is a discrepancy of very nearly one-thousandth part of an inch.

Adopting the authorized value 39·1393 for the length of the pendulum at London, and using Vince's formula for reduction, the length of the pendulum at 45° is 39·1156 inches, and at any other latitude,

$$39 \cdot 1156\ (1 - \cdot 0027 \cos 2 \text{ lat.})$$

From this, by help of equation 10, we obtain the intensity of gravitation—

$$386 \cdot 05\ (1 - \cdot 0027 \cos 2 \text{ lat.}),$$

as measured in English inches; that is to say, a heavy body falls during the first second of time through 193 inches, or 16 feet 1 inch, in latitude 45°, and in a vacuum.

The determination of the oblateness of the earth from observations on the length of the pendulum belongs to physical astronomy. It is enough to remark here, that the irregularities of two, three, or even five seconds per day which occur among the observations, can scarcely support a speculation on the irregularity of the earth's structure, seeing that in the immediate vicinity of powerful stationary transit instruments, and with every appliance and convenience for insuring precision, there has been a disagreement of a whole second.

ATTACHED PENDULUMS.

The great utility of the pendulum lies in its application to time-keeping. This part of the subject has already been adverted to under the head CLOCK-WORK; in the present place, we shall consider a little more in detail the abstract principles which are involved.

As has been stated, clock pendulums are never suspended on knife-edges; they are hung by means of thin flat springs. The elasticity of these, and the form which they take on being bent, cause a deviation from the circular motion, the effect of which has not been rigorously investigated, but which evidently tends toward the condition of cycloidal motion; so that the errors caused by changes in the amplitudes must be less than in the case of the knife-edge suspension.

The wheel-work of the clock performs the double function of recording the number of oscillations and of maintaining the motion; and the perfection of its action requires that it never miss count, and that it preserve a constant amplitude. Now, nothing short of perfect workmanship can secure the attainment of the latter condition; and therefore the primary object in contriving the parts of the movement is to arrange them so that a variation in the maintaining power may produce no perceptible change in the daily rate, for which purpose the natural motion of the pendulum must be interfered with as little as possible.

The progress of the wheels cannot be continuous, for then the extent of the oscillation would depend on the dimensions of the parts: the wheel-work must then move by steps; and therefore its action must consist of three distinct parts,—viz., the *detention*, the *release*, and the *impulse*. The apparatus for accomplishing these three actions constitute what is called an *escapement*.

In some escapements the detention is effected by allowing a tooth to rest upon some part of the pendulum; in such cases the detaining surface must be exactly or nearly concentric with the motion of the pendulum; if it be truly concentric, the wheels remain perfectly stationary during the detention, and the escapement is called *dead-beat;* but if, as in the earlier clocks, the detaining surface be inclined, the wheels move backwards and forwards during the detention, and the escapement is called *recoil.* The recoil escapement is so obviously faulty that one is puzzled to account for its having remained so long in use, particularly when we reflect that a very slight change in the form of the parts converts it into a dead-beat.

In these escapements the *release* is effected by allowing the tooth to slip off one end of the detaining surface. In the case of the simple dead-beat the end of the detent is sloped a little from the radial direction, in order that the tooth in descending along it may give the impulse; or the tooth itself is so shaped that it may produce the same effect. When the impulse has been given, another detaining surface has come into such a position as to oppose the motion of another tooth, and the blow produced by this contact *beats* the second. For counting, this kind of escapement is decidedly the best.

In the duplex escapement, when the long tooth slips off the detent, the wheel turns rapidly through a distance which the clockmaker arranges to be as small as possible, until the impulse-tooth fall upon, or rather overtake, the pallet; this produces a slight sound. When the impulse has been given, the impulse-tooth is relieved from the pallet, and the escape-wheel turns rapidly, but again only through a small distance, until the alternate detent stop the next long tooth. This last action is accompanied by a more distinct beat, indicating the second; but the astronomer, unless placed at such a distance as not to hear the preceding slight sound, finds it more difficult to estimate the fractions of a second with this than with the former escapement.

For the purpose of avoiding entirely the rubbing during the detention, a separate detent is provided, on which the tooth may fall. This detent and the wheel-work remain stationary until the release be effected by some part of the pendulum coming in contact with and lifting the detent, so as to permit the impulse to be given: escapements of this class are called *detached.* The now very common *detached lever* and the *chronometer* escapements are characteristic though dissimilar examples of this class. Because of the number of abrupt actions, each accompanied by a slight sound, neither of them is well adapted for minute observations, unless the ear be so far removed as not to catch the lesser sounds.

In discussing the comparative merits of different kinds of escapements, it would be tedious to enter into the peculiarities of their construction; it will be enough to examine their actions under the general heads of *detention, release,* and *impulse.*

In the common dead-beat, and also in the duplex escapement, the friction of the detained tooth upon the circular arc is nearly constant; but the influence of a constant friction upon the motion of a pendulum has not been strictly investigated; so that we have nothing better than approximation to guide us. It can easily be shown that a constant friction acting upon the balance of a watch, in which the redressing tendency is proportional to the distance from the point of rest, produces no change in the time of the oscillation, and only displaces, first to one side and then to the other, the middle of the arc; and we have shown above that a friction varying as the cosine of the obliquity produces both a displacement of the arc and an imperceptible acceleration on the pendulum; wherefore we may conclude that, with a small arc of oscillation, the effect of friction on the clock's rate must be very trifling. The most serious effect is, the diminution of the amplitude, which necessitates a more powerful impulse. In respect of this, the duplex is decidedly preferable to the simple dead-beat; but the detached escapements have the advantage over both, since they occasion no friction at all.

The release in the dead-beat and duplex escapements is merely the end of the detention; the tooth slips off the detaining arc. But in detached escapements the release is a distinct action; the detent has to be removed from before the tooth. In the chronometer escapement the detent is kept in its place by a spring, which must be bent backwards when the detent is raised, thus causing a retardation through a small part of the arc. The comparative value of the two classes of escapements must depend to some extent on whether this resistance of the detent or the friction on the pallet be most injurious to the time-keeping. The watchmaker gives a motion as extensive as possible to the balance, while the clockmaker's aim is to render the arc as small as he can; and thus the advantages of the detached escapement are greater in watch than in clock work.

When the release has been accomplished, the wheels are impelled forward, but not instantaneously. They acquire velocity gradually, until arrested by the stroke of the impulse-tooth upon the pallet.

In a common dead-beat escapement, let A (fig. 10) be the axis of the crutch, C that of the escape-wheel, and T the tooth, which, having been detained upon the surface EF, is just released by the motion of the pendulum towards the right. The pallet continues its motion, and the tooth begins to descend according to the ordinary law, its distances being proportional to the squares of the elapsed times. In consequence of these two motions, T would trace upon a surface attached to the crutch a paraboloid curve FG, tangent to the arc EF at F; and if the end of the pallet were exactly shaped to this curve, the tooth would merely graze it, without communicating any impulse.

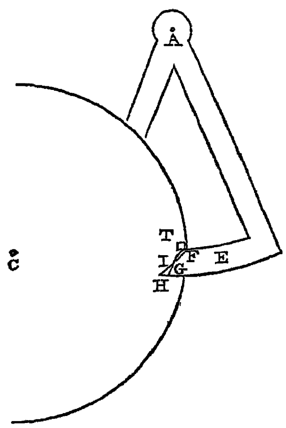

Fig. 10.

When the end of the pallet is bevelled, as FH, making a sharp corner at F, the tooth falls behind at first, gains speed, and overtakes the pallet at I; so that the impulse is only given from I to H. Although the interval FI be so small as to escape observation, it is not the less real, and as its tendency is to cause a slight uncertainty in the action, it ought always to be obviated by rounding a little the corners of the ruby. It is completely removed in those escapements which have the tooth T part of a cylinder.

But this interval exists unavoidably in the duplex and in the detached escapement. Its extent in all cases is augmented by an increase in the weight of the escape-wheel, for which reason that wheel ought to be made as light as is consistent with accuracy and permanency of form.

The great derangement of the time-keeping is from the impulse. Friction, imperfect elasticity, and the air's resistance, are injurious chiefly because they render an impulse necessary; and the important matter in contriving an escapement is to place the arc of impulse so as not to influence the time of the oscillation.

The effect of the impulse can be strictly investigated when the redressing tendency is proportional to the derangement; and it can be shown (*Edin. New Phil. Jour.* for July 1835) that the proper time for the impulse is nearly at the middle of the oscillation; but when, as in the

case of the pendulum, the redressing tendency is proportional to the sine of the inclination, the inquiry transcends the power of the calculus. We may, however, satisfy ourselves that the impulse ought to be given when the pendulum is near its lowest point by considerations which do not require any elaborate formulæ.

The impulse is to restore the motion that has been lost by friction and the air's resistance; and therefore the product of the impelling pressure, by the distance through which it acts, must be equal to that of the resistance by its distance. Its effect upon the pendulum is to augment the square of the velocity by a certain quantity, and to shorten the time in which the arc of impulse is passed over. If V be the velocity which the pendulum would have had at the end of the arc of impulse if let alone, and V′ the velocity which it has after having received the impulse, we have $V'^2 - V^2 = I$, or $(V' + V)(V' - V) = Pi$. When the impulse is given near the middle of the arc, $V' + V$ is large, and therefore $V' - V$ small; but when it is given near the limit of the motion, $V' + V$ is small, and therefore $V' - V$ proportionally great. Now i being the extent of the arc of impact, $\frac{i}{V}$ is the time during which it would have been described with the velocity V, and $\frac{i}{V'}$ that with the velocity V′; hence $\frac{i}{V} - \frac{i}{V'}$ is proportional, approximately, to the direct influence of the impulse upon the time of an oscillation. This may be put under the form $i\,\frac{V' - V}{VV'}$; and it is to be observed of this fraction that its numerator is inversely proportional to $V' + V$, whence $\frac{i}{VV'(V+V')}$ represents the error in time-keeping caused by the impact.

From this we conclude, that when the change $V' - V$ is not great, the error caused by the impulse is inversely as the cube of the velocity of the pendulum at the time of receiving it; and also that the shorter the arc, the pressure being proportionally augmented, the less the derangement is.

Now, neither the detached escapement nor the duplex can be used with a very small arc of impulse, as the risk of missing would be great; while the simple dead-beat can have that arc reduced by an alteration on the forms of the tooth and pallet; so that, considering its smooth, quiet action, and the facility which it gives for reducing the direct error of the impulse, we need not wonder that it is regarded as, practically, the best escapement.

REMONTOIRES.

As the maintaining power is communicated to the pallets through a long train of wheels, it is liable to periodical variations from malformation of the teeth, and to more permanent changes from dust, and from the thickening of the oil. Also in spring time-keepers the form of the fusee does not compensate perfectly for the varying tension of the mainspring. Hence the utility of what are called *remontoires*, or re-winders.

This name is given to various arrangements by which a small weight or slender spring, as the case may be, is wound to a determinate height at short intervals of time, this weight or spring becoming virtually the maintaining power. If the remontoire be made to act every minute, the seconds hand proceeds as usual, but the minute and hour hands spring forward by one minute at a time. The periodical inequalities are in this case repeated every minute, and cannot accumulate to become perceptible; while, as all the parts above the remontoire can be highly finished or jewelled, the variations of friction are little felt.

When the re-winding occurs every second, the arrangement becomes what is known under the name of the *gravity escapement*. In the greater number of gravity escapements the impulse weight is held by the clock-work at a fixed height until the pendulum relieve it and carry it to the extremity of the oscillation. During this part of the action the weight retards the motion; but when the pendulum begins to descend, the weight descends also, and as it is not arrested till it has reached a point lower than that from which it started, it accelerates more than it retards the pendulum. When the impulse-weight has reached its lowest point, the detent is unlocked, and the wheel-work raises the weight to its first place, there to await the pendulum.

In electric clocks, galvanic contact is made or broken at the proper instant, and the impulse-weight is lifted by the electro-magnet.

These escapements are essentially recoil escapements, and have all the defects which are inseparable from the class. An extraneous influence cannot be brought to bear on the pendulum at a worse place than at the extremity of the motion, where the velocity is zero. And seeing that, for good time-keeping, the arc of impulse must be very short, it cannot but be detrimental to lengthen it out over a half oscillation. These escapements, in fact, are in direct opposition to the principles which have just been explained.

METRONOME PENDULUMS.

We have seen that the length of simple pendulums vibrating in different times are proportional to the squares of those times, and that these lengths are fixed by the intensity of gravitation; thus a simple pendulum vibrating once a second must be about 39 inches long. But it does not follow that a compound pendulum must have this length.

For the purpose of marking time, musicians employ an instrument called a *metronome* (fig. 11), of which the principal part is a small pendulum capable of being regulated to suit the character of the opera, B being the principal weight of this pendulum, and A the axis of motion, the rod BA is prolonged above the fulcrum, and on the prolongation AD an adjusting weight C is made to slide; divisions also are engraved and numbered on AD, to indicate the number of beats which the pendulum makes per minute.

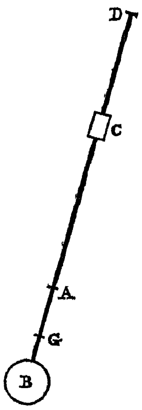

Fig. 11.

If m_1, m_2, m_3, &c., represent the masses of which a pendulum is made up, r_1, r_2, r_3, &c., their distances from the axis of motion, and if AG be the distance of the centre of gravity from that axis,—

$$\frac{m_1r_1^2 + m_2r_2^2 + m_3r_3^2 + \&c.}{AG\,(m_1 + m_2 + m_3 + \&c.)}$$

expresses the length of the simple pendulum vibrating in the same time.

Now, by raising the weight C, we augment the numerator of this fraction, and at the same time lessen the denominator, since the centre of gravity is also raised, so that we lengthen the time of the oscillation. If C were raised so high as to bring the centre of gravity up to A, the mean distance of oscillation would become infinite; so that there is no degree of slowness that cannot be attained by this arrangement.

If M be the weight of the permanent part of the metronome pendulum, including the axis and pallets, R its mean distance of gyration round the axis, and l the distance of its centre of gravity, then

$$L_0 = \frac{MR^2}{Ml}$$

is the mean distance of oscillation of the unloaded metronome. And if m be the weight of the sliding-piece, ρ its mean distance of gyration round an axis passing through its own centre of gravity parallel to the axis of the pendulum, and λ the distance of its centre of gravity above that axis,

$$L=\frac{MR^2+m\rho^2+m\lambda^2}{Ml-m\lambda}$$

is the mean distance of oscillation of the loaded metronome. The weights M and m can be determined directly, and the length L_0 can be obtained by observing the oscillations of the pendulum when unloaded, using the equation

$$l=t^2\times 39.1393;$$

by this means we can eliminate MR^2, and the equation

$$\frac{Ml}{m}L-\left(\frac{Ml}{m}L_0+\rho^2\right)=\lambda^2-L\lambda$$

expresses the relation between L and λ. In this there remain still the quantities l and ρ to be determined by experiment. By placing the weight C at three different positions on the stem, and observing the times of oscillation, these quantities l and ρ can be found, and thence the graduation of the instrument.

However, as the matter does not call for extreme precision, the ordinary method of finding by trial three or four points on the scale, and then graduating between, is sufficient for the purpose.

COMPENSATION PENDULUMS.

The expansions and contractions of the pendulum-rod, consequent on changes of temperature, are sources of great irregularity in the going of clocks. Thus, iron wire expands, according to M. Biot, $\frac{1}{812}$th from freezing to boiling water, and therefore this change of temperature would cause an alteration of 53 seconds in the daily rate; that is, very nearly 3 seconds for every 10 degrees of Fahrenheit's thermometer. A piece of white deal expands only about the third part as much as iron; and hence the irregularity of a pendulum with a deal rod is only about 1 second per day for a change of 10 degrees Fahrenheit. A well-made clock, with a deal-rod pendulum, is sufficiently accurate for the ordinary purposes of life; but where great nicety is required, means are taken to correct the effects of expansion.

As this part of the subject has already been adverted to under the head CLOCK-WORK, it is enough, here, to indicate the general features of the investigation.

A very simple and inexpensive compensation pendulum may be made of a cylindric deal rod carrying a long leaden cylinder; and if the rod be composed of several slips, well glued together, and thoroughly varnished, to prevent the effects of the moisture, there is perhaps no pendulum yet contrived which will keep better time.

Fig. 12.

The strict investigation into the effects of a change of temperature upon a clock furnished with such a pendulum would take into account—1*st*, The weight, form, and expansion of the crutch and its appendages, since these form an essential part of the oscillating mass; 2*d*, The expansion and change of stiffness of the slender steel spring AB (fig. 12); 3*d*, The expansion, lateral as well as longitudinal, of the deal rod BC; and, *lastly*, The expansion of the perforated leaden bob CD, and the thermal compensation, will be effected when the various dimensions are arranged; so that the numerator and denominator of the fraction

$$\frac{\Sigma\,.\,mr^2}{AG\,.\,\Sigma m}$$

receive proportional augmentations on an increase of temperature. Now it is evident that the square of the temperature will be found in the new numerator, while only its first power can enter into the denominator; and thus we see that no compensation can be *perfect* for every change of temperature. However, as the expansions are all minute, the second powers of the fractions which represent them may be neglected without causing any appreciable error.

There is a great uncertainty as to the rates of expansion of different bodies, arising partly from the difficulty of making the measurements, and partly from irregularities among different specimens of the same substances. On this account, it would be a waste of labour to compute the conditions of compensation strictly—the more so, that the fine adjustment must be made by trial; we shall content ourselves with an analysis on the supposition that the parts are merely linear, and that the pendulum is swung from a knife-edge.

If m_1 and m_2 be the weight of the deal rod AC, and of the leaden bob CD, the mean distance of oscillation is

$$l=\frac{2}{3}\frac{m_1\,.\,AC^2+m_2\,(AC^2+AC\,.\,AD+AD^2)}{m_1\,.\,AC+m_2\,(AC+AD)}$$

for the temperature at which the measurements are made; and if e_1, e_2 be the rates of expansion for one degree, while AC and CD are denoted by H and h, the condition of compensation is expressed by the equation

$$\frac{m_1H^2+m_2\,(3H^2-3Hh+h^2)}{m_1H+m_2(2H-h)}$$
$$=\frac{m_1\,(2H^2e_1)+m_2\,(6H^2e_1-3Hh\,(e_1+e_2)+2h^2e_2)}{m_1\,(He_1)+m_2\,(2He_1-he_2)}.$$

Again, if we suppose that the weight m_1 of the rod is insignificant in comparison with m_2, the equation becomes much simpler, and reduces itself to the form

$$e_2h^3-(4e_2+e_1)Hh^2+(3e_2+6e_1)H^2h-6e_1H^3=0;$$

so that, even in this most simple case, the determination of the ratio of h to H requires the resolution of a cubic equation.

Supposing that for deal $e_1=\frac{1}{2400}$, and that for lead $e_2=\frac{1}{350}$, we have $e_1:e_2::7:48$, and the equation becomes

$$48h^3-199h^2H+186hH^2-42H^3=0;$$

whence very nearly $H=3h$; that is, the column of lead must be one-third part as long as the deal-rod; and for a seconds pendulum the whole length must be about 46·35 inches; the leaden bob being 15·45 long.

ATMOSPHERIC INFLUENCE.

The effect of the buoyancy of the air upon the going of a clock is considerable: thus lead is about 9000 times heavier than air of the same volume, and therefore a change of one inch in the barometer will alter the apparent weight of the leaden bob by one part in 270,000, which corresponds to an alteration in the daily rate of the clock of $\frac{16}{100}$ths of a second, or rather more than one second per week; and as the whole of the pendulum is not made of such weighty materials, the actual derangement must be somewhat more than this. It is thus impossible, in a climate so variable as ours, to construct a clock that shall keep true astronomical time, unless it be cased and protected entirely from changes in the buoyancy of the air, or unless some means be fallen upon to compensate for atmospheric changes.

In the delicate operation of determining the apparent right ascension of a star or planet, the time of transit over the wires of the telescope is sought to within a small fraction, as the twentieth or fiftieth part of a second. We must be able, therefore, to depend on the going of the clock from one observation of a standard star till another within this degree of precision, otherwise the care bestowed on the collimation of the instrument is thrown away. Now a rise of half an inch in the barometer will, in twelve hours, produce a retardation of $\frac{1}{24}$th of a second; so that, if an

astronomer aim at precision in his observations, he must be able to make allowance for the effect of the air's buoyancy on the going of his clock.

By carefully collating the observed variations in the clock with the indications of the thermometer and barometer, an empirical formula may be constructed, by means of which the error may be computed up to any given time.

When steel or iron rods enter into the composition of the pendulum, an error of another kind is induced. The rod, particularly in latitudes where the needle dips much, becomes magnetic, and is then influenced by the earth's magnetism. The amount of this influence increases until the maximum magnetism is induced; and thus newly-made clocks which have steel and mercury compensation pendulums are liable to show an acceleration of rate for a considerable time after they are set up; they are also liable to changes of rate depending on variations in the intensity of the earth's magnetism.

CONICAL PENDULUM.

When a pendulum, instead of being hung on an axis which restricts its motion to one plane, is hung on a point merely, its movements are much more complex. Laplace has partially investigated the case of a single material point suspended by means of an imponderable thread; but the general subject has hardly yet been inquired into.

If the motion of a simple pendulum be restricted to a very minute distance from the point of rest, it describes almost exactly an ellipse; but whenever the amplitudes become perceptible, the major axis of the curve turns in space so as to imitate in some respects the motion of the line of apsides of a planet. When, however, the pendulum is compound, a much more intricate movement takes place.

To illustrate the nature of this complex motion, let us suppose that a pendulum of irregular shape is swung from a Hooke's universal joint, the two axes of which are parallel to the horizontal axes of greatest and least rotation. Then if the pendulum be drawn aside in the direction of one axis, and let go, it will continue to oscillate on the other axis; but the times of the oscillation on these axes will not be the same: let us represent them by T and t. If now the pendulum be drawn aside in a direction not parallel to either axis, both oscillations will go on conjointly. The determination of the complex motion thus induced is too difficult for the calculus in its present state; if, however, we restrict the amplitudes to be exceedingly minute, the form of the curve may be obtained by the following process:—

Assume O (fig. 13) as the central position, A O a, B O b as the extents of the oscillations parallel to the two axes, then the rectangle C D c d circumscribes the curve. On cD and DC describe two semicircles, and divide each of them into equal parts, the numbers being proportional to the times T and t (the ratio assumed in the adjoining fig. is 5 : 3), and through the points of section draw lines parallel to the sides of the rectangle. Then, beginning

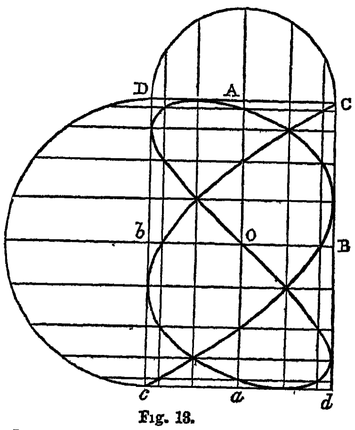

Fig. 13.

at any of the crossings, let a curve be traced diagonally through the adjoining meshes; this line represents the path of the pendulum. It is of the same nature with the curves described by the free extremity of a straight wire held firmly by the other end.

If the periodic times of the oscillations be nearly alike, the curve assumes the appearance of an ellipse, of which the major axis oscillates between the diagonals Cc and Dd, and which collapses into a straight line in each of them.

When, however, the amplitudes are considerable, this method fails to give a correct representation of the movement.

If the suspension could be by means of a thread offering no resistance to torsion, the motions of an irregular mass would be still more complex; and when the cord resists torsion, an oscillatory-rotatory motion is superadded, and the complexity becomes enormous.

One species of conical pendulum deserves attention as being used for regulating the speed of steam-engines and water-wheels. In it the pendulum is hinged on a horizontal axis, which is caused to revolve round a vertical one, and the effect of the motion is to throw the pendulum aside from the vertical position. If there were no friction on the hinge, the rotatory motion would be combined with an oscillatory motion on the horizontal axis; but in the actual apparatus, the friction and other resistances destroy the oscillation, while the rotation is kept up by the machinery; and, on this account, the only object of interest is to determine the degree of inclination which belongs to a given speed.

Let AB (fig 14) be the vertical axis of a governor, C and C′ the hinges, G and G′ the centre of gravity of the two pendulums; then having drawn GD perpendicular to AB, GD is the radius of the circle described by G, and therefore, if T be the time of a rotation, $m\frac{4\pi^2}{g}\frac{\mathrm{DG}}{\mathrm{T}^2}$ is the centrifugal tendency in the direction DG; and the resultant obtained by combining this with m in a vertical direction must lie along CG; wherefore, having produced GC to meet AB in E—

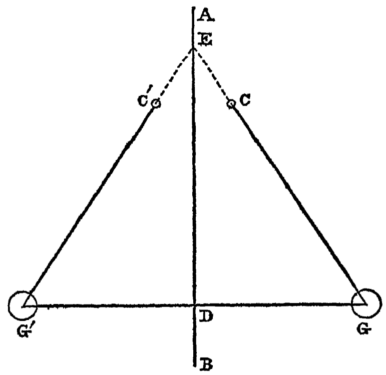

Fig. 14.

$$\tan \mathrm{DAC} = \frac{4\pi^2}{g}\frac{\mathrm{DG}}{\mathrm{T}^2} = \frac{\mathrm{DG}}{\mathrm{ED}};$$

$$\text{whence } \mathrm{ED} = \frac{g}{4\pi^2}\mathrm{T}^2.$$

If we notice that in reckoning the oscillations of a pendulum we counted from one side to another, whereas a complete oscillation requires a return to the same place, we shall see that the height DE of the conical pendulum is equal to the length of a simple pendulum oscillating along with it.

FOUCAULT'S EXPERIMENT.

When a round body, suspended by means of a flexible thread, is once set to oscillate in a plane, it continues to move in that plane. M. Foucault has taken advantage of this property in order to demonstrate the diurnal rotation of the earth. If the earth were at rest, the direction of the vibrations would remain, and would appear to remain, fixed; but as the earth turns while the plane of oscillation preserves its parallelism, that plane appears, in reference to surrounding objects, to turn in the direction of the apparent motion of the stars.

In repeating this beautiful experiment, care must be taken that the weight be symmetric in shape, and that no bias be given at the outset, lest some of the complex movements above mentioned be induced. (E. S.)

PENEDO, a town and district of Brazil, in the province of Alagoas, on the left bank of the São Francisco, 60 miles S.W. of Alagoas. The town is large and well built, partly on the bank of the river, and partly on the slope of a hill. It contains several churches and schools, a town-hall, and a Franciscan convent. The adjacent country produces in abundance cotton, rice, pulse, millet, and mandioc. Pop. of the district, 14,000.

PENELOPE, the wife of Ulysses, and mother of Telemachus, was famous for her conjugal constancy. During the long absence of her husband, numerous suitors sought in vain to win her hand. She constantly put them off by declaring that she must finish the shroud which she was then weaving before she could listen to their proposals. At the same time, she continued to undo during the night that part of the woof which she had done during the day. This stratagem kept them at bay until the arrival of Ulysses.

PENIG, a town of Saxony, circle of Leipsic, on the right bank of the Mulda, 35 miles S.S.E. of Leipsic. It contains a Gothic church built chiefly of porphyry, two ducal castles, a court of law, bleachworks, and cotton, silk, and paper manufactories. Pop. 4817.

PENINSULA (*pene*, almost, *insula*, an island) is a portion of land almost surrounded by water.

PENITENCE, or PENANCE, is one of the seven sacraments of the Church of Rome. Penitence is sometimes used for a state of repentance, and sometimes for the act of repenting. It gives title, besides, to several religious orders, consisting either of converted debauchees and reformed prostitutes, or of persons who devote themselves to the office of reclaiming them. Of this latter kind is the *Order of Penitence of St Magdalen*, established about the year 1272 by one Bernard, a citizen of Marseilles, who devoted himself to the work of converting the courtezans of that city. Bernard was seconded by several others, who, having formed a kind of society, were at length erected into a religious order by Pope Nicholas III. under the rule of St Augustin. F. Gesnay says they also constituted a religious order of the penitents, or women they converted, giving them the same rules and observances which they themselves followed. The "Congregation of Penitents" at Paris was founded with a similar view.

PENKRIDGE, a market-town of England, in the county of Stafford, on the Penk, an affluent of the Trent, here crossed by a stone bridge, 5½ miles S. of Stafford, and 131 N.W. of London. It consists of two principal streets, uniting near the bridge; and contains a parish church with a square tower, places of worship belonging to Methodists and Independents, and a national school. The lower part of the town is subject to inundations of the river. There are 3 annual fairs; and yearly races are held in September. Pop. (1851) 2663.

PENN, WILLIAM, founder of the state of Pennsylvania, and the most accomplished Englishman that ever joined the Society of Friends or Quakers, was a native of London, born October 13, 1644. He was the eldest son of a brave naval officer, one of the sea-captains of the Commonwealth, who, after the Restoration, rose to the rank of admiral, was knighted by Charles II., and appointed a commissioner of the navy. In the flag-ship of the Duke of York, Admiral Penn held the post of "Great Captain Commander," and was with his royal highness in the decisive victory over the Dutch off Harwich in 1665. An intimacy was thus formed between the prince and the admiral which had an important influence on the fortunes and character of the admiral's son, the Quaker preacher and legislator. In his fifteenth year William Penn was entered a gentleman commoner of Christ Church, Oxford. Polemical controversy and religious fervour, under various forms, then agitated the country; the university partook of the excitement, and Penn joined the serious or puritanical class of students who waged war against the surplice and high church ceremonial patronized by the court. He attended the preaching of a Quaker named Thomas Loe, neglected the college rules and discipline, and was fined: he became still more contumacious, and was expelled. Admiral Penn, a worldly, ambitious man, who looked forward to a peerage, was inexpressibly chagrined and mortified by this strange conduct on the part of his son and heir. He adopted, however, a mild and judicious mode of treatment; he sent the young Nonconformist abroad in company with some friends, to make the tour of France and Italy. The experiment was completely successful. Withdrawn from the Oxford influences, William Penn became the fine gentleman and man of the world. He remained abroad two years, and on his return to England, was introduced to the court, where his polished manners and handsome appearance soon rendered him a favourite. In order to fit him for public life, his father entered him as a student of Lincoln's Inn, and employed him also on his own private affairs. In June 1665 the plague broke out in London. That awful visitation, which carried terror to every heart and struck down thousands in the capital, revived all William Penn's serious and self-abasing impressions. He abandoned the licentious court, left off visiting the gay circles that swarmed around "the merry monarch, scandalous and poor," and, shutting himself up, took to the study of controversial and practical divinity. His father saw that it was again time to interfere. He had property in Ireland, a valuable barony in the county of Cork, which had been granted by the king in exchange for an estate bestowed on the admiral by Cromwell. The new grant was disputed by local claimants, lawsuits were instituted, and negotiations were necessary to settle the matter. William Penn had already shown his aptitude for business, and his father despatched him to Ireland, recommending him in an especial manner, by introductory letters, to the care of the Duke of Ormond, then viceroy of Ireland. At the court at Dublin Penn was a welcome visitor; and an insurrection breaking out at this time among the military at Carrickfergus, he served for a short period as a volunteer. In his capacity of soldier Penn displayed so much coolness and bravery that he was offered the command of a company. For a moment visions of military glory seem to have dazzled the future apostle of peace; but his father, not dreaming of another relapse to the Quaker rule, and sensible of the value of the services rendered to his family by his son's management of the Irish estate, opposed himself to this intended military destination. A crisis was at hand. William Penn happened to visit Cork; Thomas Loe was there on a Quaker mission; and curiosity led Penn one day to attend the preaching of his former Oxford acquaintance. The circumstance was decisive. All his former enthusiasm came back upon him with augmented force; he joined the hated and despised sect; and shortly afterwards was, with the rest of the congregation, sent to prison on the usual charge of riot and tumultuous assembling. His friends at the viceregal court procured his release, and the admiral sent for him home. The meeting must have been a painful one on both sides. To the rage and expostulations of his father the neophyte opposed calm answers and subtle arguments. He got a short time to deliberate—retired, prayed, and was immoveable in his resolution to adhere to the new doctrines. His father turned him out of doors! The die was now cast; Penn was elevated to a sort of martyrdom, and he seems to have exulted in his emancipation from all worldly compromise and restraint. He set himself vigorously to prosecute what he conceived to be his Divine mission. His father, after a few months' absence, permitted him to return home, but would not see him; and we may conceive

the astonishment and disgust with which the courtly admiral read the title-page of his son's first exposition or defence of Quakerism—a work thus set forth as a flag of defiance to all gainsayers:—

"TRUTH EXALTED, in a short but sure Testimony against all those Faiths and Worships that have been formed and followed in the darkness of Apostacy; and for that Glorious Light which is now risen and shines forth in the life and doctrine of the despised Quakers, as the alone good old way of Life and Salvation. Presented to Princes, Priests, and People, that they may repent, believe, and obey. By WILLIAM PENN, whom Divine Love constrains in an holy contempt to trample on Ægypt's glory—not fearing the King's wrath, having beheld the Majesty of Him who is Invisible."

This work appeared in 1668, in William Penn's twenty-fourth year. It is a crude, fanatical, acrimonious production, directed against all sects except that of the Quakers, and against all those "idolatrous, superstitious, carnal, proud, wanton, unclean, mocking, and persecuting princes, priests, and people" who should "go on to rebel against the reproofs and instructions of this holy light." Another work published by Penn the same year, entitled *The Sandy Foundation Shaken*, is less wildly vehement and more argumentative. It attracted a good deal of attention, and replies to it, he says, were thundered forth in books and from the pulpit. This notoriety led to a consummation very common in those persecuting times—a false charge of sedition was trumped up against Penn, and he was committed to the Tower. He was confined for eight months, the patient victim of intolerance; and he occupied himself by writing a more elaborate exposition of his doctrines and belief, which he entitled *No Cross no Crown*. This is the best of his theological treatises, and was the most popular. He enforces with great earnestness and ability (quoting largely from Scripture) the leading Quaker tenet, that to do well with constancy and bear ill with fortitude is the only way to attain lasting happiness; and he adds a series of "testimonies" drawn from the lives and writings of eminent men, ancient and modern. These selections evince considerable reading and research, and in subsequent editions he enlarged the number. It is worthy of remark, that though he praises the wit and morality of Cowley, he nowhere alludes to his great contemporary Milton, who was not only conspicuous for his advocacy of religious freedom, but was even suspected of a leaning towards Quakerism. Some doctrines or opinions of the Quakers Milton undoubtedly held; but his bold speculations and majestic genius were both above the range of the ordinary sectaries of his day. If known at all to men like Penn, he must have been regarded rather with fear and wonder than with confidence or admiration. The blind poet and patriot held aloof from all sects and "dwelt apart;" but in one instance at least tidings of Penn must have reached Milton in his small house in the Artillery Walk, and drawn from him, and from his friends Andrew Marvell and Cyriack Skinner expressions of warm sympathy and hearty approbation. The Conventicle Act prohibiting dissenters' meetings was renewed in the spring of 1670. William Penn was one day found addressing a crowd in the street, and, along with another Quaker named Mead, was taken up and committed to Newgate. They were tried at the next Old Bailey sessions before the mayor, recorder, aldermen, and sheriffs, and the trial was marked by all the coarse and brutal insolence which unrestrained power generates in vulgar minds. Penn, however, vindicated the principles of English freedom and the rights of conscience with admirable intrepidity and talent; the indictment was proved to be wrong both in its statements of law and of fact; and the whole proceedings were so glaringly and monstrously unjust, that the jury refused to return any severer verdict than that of "Guilty of speaking in Gracechurch Street." Again and again were they turned back and browbeat by the bench; they were kept two days and two nights without food, fire, or water, but the stout English spirit was strong within them, and it was found impossible to extort a verdict agreeable to the court. Their last decision was "Not guilty," and for this they were fined forty marks each, with imprisonment in Newgate until the fine should be paid. Penn and Mead were also fined for contempt of court. All of them went to Newgate. The jurors appealed to the Court of Common Pleas against the mayor and recorder; the appeal was sustained; and Penn had thus the triumph of overcoming his oppressors, and establishing the principle, that it is the right and the special function of juries to judge of the value of evidence, independent of any direction or attempted coercion of the court. Penn followed up his victory by the publication of a full report of the case, *The People's Ancient and Just Liberties asserted*, &c., accompanying the report with some forcible and pungent remarks. Altogether this trial and publication—the firmness of the twelve London citizens, and the impartial award of the Court of Common Pleas, for all which we stand indebted to Penn—form a great landmark in the progress of our popular and constitutional liberties.

Admiral Penn was now dying. The courage and ability of his son gratified the parental pride and affection, and a complete reconciliation took place. "Son William," said the admiral, "if you and your friends keep to your plain way of preaching, and also keep to your plain way of living, you will make an end of priests!" To accomplish any approach to such a sweeping result, persecution, however, would have been necessary. When the Quakers were permitted to meet unmolested, and to speak, preach, and dress after their own peculiar fashion, their importance was gone, and their exclusive self-denying doctrines were not likely ever to become general.

During the next ten years, from 1670 to 1680, Penn continued to write, preach, and hold public disputations in defence of Quakerism. He was six months in Newgate (in 1671), convicted of frequenting an "unlawful assembly;" and in those six months he wrote and published four treatises, one of which, *The Great Case of Liberty of Conscience*, is a good comprehensive statement of a great principle then little understood. He travelled in Holland and Germany, interceded with foreign states in favour of the victims of persecution, and in 1676 became one of the proprietors of West Jersey in America, and was instrumental in colonizing that province by the English. At home he was associated with Algernon Sidney in endeavouring to obtain some mitigation of the severity against dissenters; and before the infamous Popish plot of Titus Oates had driven the nation into a paroxysm of insane fury and intolerance, he was permitted to address the House of Commons in behalf of those persons who were suffering penalties for conscience sake. There was, however, little prospect of emancipation in England, and Penn applied himself to found a religious democracy in the New World. The government stood indebted to the family of Sir William Penn in a sum of about L.15,000; the claim was just and undisputed; but the exchequer of Charles II. was rarely in a condition to meet such a demand. In lieu of a money settlement, Penn solicited, and after some delay obtained, by letters patent from the Crown, a grant of land on the River Delaware, a vast province that had belonged to the Dutch, 360 miles in length by 160 in width. It had been called New Netherlands, but as the territory was mountainous, he proposed to name it New Wales. A Welsh secretary of state, Blathwayte, objected to this appropriation; and Penn substituted Sylvania, in reference to the great forests which covered the land. King Charles, in honour of his late friend the admiral, suggested the prefix of *Penn;* and thus the new province bore, in the royal charter, the liquid and euphonious name of Pennsylvania.

"God hath given it me in the face of the world," said Penn in the fulness of his heart; "He will bless and make it the seed of a nation;" a prophecy which even one century, a fragment in the history of a people, saw fulfilled.

In framing a constitution for his new colony, Penn was assisted by Algernon Sidney. That fearless politician, whose tendencies were all towards republicanism, brought ample knowledge of ancient and modern governments to the task. Penn, less enlightened, but perhaps more practical, knew and felt deeply the value of religious liberty. That sheet-anchor he never would forego, and there were no traditional associations to bind the lawgivers. Two still greater men of that age, Milton and Locke, drew up forms of government. Locke's scheme was tried at Carolina, and proved a failure. Milton's ideal republic was an intellectual aristocracy that never could have been realized with Englishmen. But Penn and Sidney made their scheme of Christian democracy essentially popular in its character, with a council and assembly elected by universal suffrage, and with ample scope for the future development and improvement of the colony. (The progress of Pennsylvania, under this enlightened system of local government, will be found described under PENNSYLVANIA.) Trading companies were soon organized; and emigration proceeded from London, Bristol, and Liverpool. Penn himself sailed for his new domain in the autumn of 1682. His voyage in the ship Welcome, his enthusiastic reception, his laying out the city of Philadelphia—that city in which, as springing from the seed sown by Penn, the great declaration of American independence was discussed and adopted,—and his solemn conference with the Indian chiefs and warriors, are proud and interesting materials of history. Who can ever forget the memorable signing of the Great Treaty, the only treaty upon record, according to Voltaire, that was never sworn to and never broken? Who does not picture in imagination that scene on the banks of the Delaware, under the magnificent old elm-tree, at which the Indian king, attended by his *sachems* and younger warriors, and the English governor, accompanied by his pilgrim-followers, interchanged pledges of amity and brotherhood,—invoking the Great Spirit, the common Father of all, to bless and ratify that scroll which was to unite for ever the Christian and the red man, the wild children of the Six Nations with the intrepid adventurers from the Old World; who were to carry civilization and commerce, equity, mercy, and peace, into the far wildernesses of the West? The annals of conquest and diplomacy, in the moment of supreme triumph, or in halls of state, furnish no parallel in picturesque or moral beauty to this simple conference on the American plain under the open canopy of heaven.

Penn landed in England on the 12th of June 1684. On the 6th of February following, Charles II. died; and Penn lost no time in waiting on the new king, and representing to him the sufferings of his Quaker brethren, imprisoned for refusing to take the oaths and attend the established church. James found that he could at once relieve the Quakers and those of his own church, the Roman Catholics; and orders were issued by which about thirteen hundred Quakers, and a still greater number of Catholics, some of whom had been confined for years, were set at liberty. Penn removed to Kensington to be near the court; he was almost daily at Whitehall closeted with the king; and such was the extent of his supposed influence, that if he had been disposed, he says, to "make a market of the fears and jealousies of the people," when James came to the throne, he could have put L.20,000 into his purse, and L.100,000 into his province of Pennsylvania. He declined every offer of reward or gratuity from those he was able to serve; the sordid vice of avarice was never charged against him. He experienced, however, the usual fate of courtiers, in being alternately envied and hated, applauded and traduced. His contemporaries said he was a Papist, holding a correspondence with the Jesuits at Rome. That amiable and tolerant divine Tillotson for a moment gave credence to the popular clamour, but was disabused of the impression by the solemn and explicit denial of Penn, who declared that he did not know one Jesuit or priest of the Romish communion. To another friend, William Popple, secretary to the Plantation Board, Penn made a fuller communication on the subject. He visited Whitehall, he said, because he had continual business there in making solicitations for his friends. His own affairs also were unsettled; and he required royal authority to restrain encroachments on his distant property. "To this," he continues, "let me add the relation my father had to this king's service, his particular favour in getting me released out of the Tower of London in 1669, my father's humble request to him on his deathbed to protect me from the inconveniences and troubles my persuasion might expose me to, and his friendly promise to do it, and exact performance of it, from the moment I addressed myself to him: I say, when all this is considered, anybody that has the least pretence to good-nature, gratitude, or generosity, must needs know how to interpret my access to the king." That access, however, was so familiar and uninterrupted during the whole of the king's unpopular reign, that we need not wonder at its exposing Penn to obloquy and suspicion. As in the classic fable, all the footsteps pointed to the royal cave; but there were few traces of mercy or favour issuing from it. Penn had witnessed the horrors of the Bloody Assizes for which Jeffreys was rewarded by his sovereign; he was present at the burning of Elizabeth Gaunt and the execution of Henry Cornish; and he saw daily the oppressions and confiscations exercised towards the Puritans and Nonconformists, with the insane efforts of James to advance and re-establish Popery. He was in several instances employed as arbiter and negotiator. All these things, it might be imagined, would have disgusted Penn with the court, and driven him, as they did Locke and Burnet, to Holland and the Prince of Orange. But he continued a courtier and friend of King James to the last. His conduct no doubt proceeded, like most actions in life, from mixed feelings or motives. His vanity was gratified by the royal attentions he received, and by the crowd of suitors that thronged his doors at Kensington. Such distinction was a pleasing novelty to one who had felt persecution, and been thrust into Newgate and the Tower: it was a public recognition of his services as a pacificator and patriot. There was also attachment to the king as his guardian and benefactor; and, above all, there was his conscientious desire and study to "allay heats and moderate animosities." If he struck off from the court, all hope of promoting religious toleration or benefiting his oppressed brethren was at an end; he was a breakwater between the royal vengeance and the noncomplying Protestants.

The latest and most brilliant of English historians, Lord Macaulay, has looked with disfavour amounting to aversion on these courtly compliances of the Quaker negotiator. He has even charged him with direct complicity in some of the most questionable transactions of the period, and with having thereby compromised his character as a man of honour and humanity, and as a consistent supporter of religious liberty. It is evident that Penn did not know James as well as Lord Macaulay, or Lord Macaulay's readers. But the worst of the historian's accusations seem to rest on imperfect evidence. They are derived from meagre reports of personal conferences, doubtful letters, and obscure despatches, which, if full information could be obtained, might be susceptible of a totally different interpretation.

The most prominent of Lord Macaulay's charges is, that Penn was a pardon-broker or extortion-agent, a character by no means uncommon in that age, when the sale of par-

dons was a regular trade. After the suppression of the Monmouth rebellion, some young girls of Taunton who had worked colours, and presented them to the unfortunate duke, were excepted from the general amnesty, and thrown into prison, in order that their relatives might purchase for them separate pardons. The money to be thus extorted was granted to the queen's maids of honour; and William Penn, according to the historian, was appointed an agent to the maids of honour, and submitted to receive instructions to make the most advantageous composition he could in their behalf. Had his name appeared on the other side as intercessor for the poor girls (who had only acted under the orders of their schoolmistress), the incident would have been in keeping with his general character; but the discredit of undertaking such a commission to gratify the rapacity of the court is foreign to all we know previously of the life of William Penn. The member for Bridgewater, Sir Francis Warre, was at first requested to exact the ransom. He excused himself, and then the Earl of Sunderland, secretary of state, wrote a letter which begins:—"Mr Penne, Her Majesty's maids of honour having acquainted me that they design you and Mr Walden in making a composition with the relations of the maids of Taunton," &c. The question arises, was the party so addressed William Penn? The slight difference in the spelling of the name Penne or Penn is a point of no consequence, for at that time, as Lord Macaulay has remarked, a proper name was thought to be well spelt if the sound were preserved. But it is of importance to ascertain whether there was not some other individual of the name to whose character, position, and circumstances, the language of Sunderland would apply. Now, it is proved that there existed at this time a certain George Penne, engaged, as the registers of the Privy Council show, as a pardon-broker at Taunton. He had been paid a sum of L.65 for the ransom of Azariah Pinney, one of the persons compromised with Monmouth. The character of this man, the spelling of his name, and the circumstance of his trafficking in pardons at Taunton, all point him out as a fit agent for the maids of honour, and warrant the conclusion that he was the person addressed by Sunderland. The minister apparently had no doubt of the willingness of his intended agent to accept the scandalous commission. The maids of honour, he says, "*design you* and Mr Walden." Is it probable that the offer, rejected by Sir Francis Warre, would have been made in such terms to William Penn, a man high at court, and the personal friend of Sunderland and the king? But if even the insulting offer were made to William Penn, there is literally no proof that he accepted it. According to Oldmixon (a bad authority, it is true, but his word may be taken on an indifferent matter when there is nothing to controvert his statement), the composition with the Taunton maids was ultimately arranged by another pardon-broker, a lawyer named Brent, who was assisted by a local agent at Bridgewater. The name of William Penn, therefore, may, we think, be considered as standing free from this degrading association. The charge rests on what we believe to be a wrong inference from a single letter in the State-Paper Office, and it is one which only the clearest and most indubitable evidence could render credible.[1]

In another case cited by Lord Macaulay, Penn, we admit, appears in a humiliating position. When the churchmen at last abandoned the doctrine of passive obedience, and refused to acquiesce in the arbitrary edicts of James, the weak and bigoted monarch endeavoured to gain over some of the more conspicuous of the dissenters. Amongst these was William Kiffin, a wealthy London merchant, and a leader among the Baptists. Kiffin had lost two grandsons, popular young men, who had joined Monmouth's rebellion, and suffered death under circumstances that excited the public compassion, and evinced the hard and unrelenting character of the king. In consequence of this severity, it was doubtful whether Kiffin would accept the offer of a city magistracy held out to him by the court. "I used all the means I could," says the old man, "to be excused, both by some lords near the king, and also by Sir Nicholas Butler and Mr Penn, but it was all in vain. I was told that they knew I had an interest that might serve the king, and although they knew my sufferings were great in cutting off my two grandchildren and losing their estates, yet it should be made up to me, both in their estates and also in what honour or advantage I could reasonably desire for myself. But I thank the Lord these proffers were no snares to me." (*Kiffin's Memoirs.*) It is painful to find William Penn engaged in such a mission, and connected, as Lord Macaulay remarks, with "the heartless and venal sycophants of Whitehall." But we know not how far he was implicated in the work of seduction. The language of Kiffin is general and obscure, and the proffers to which he refers are likely to have proceeded from the "lords near the king." Penn individually may have been passive in the transaction, though led by his attachment to the king, or urged by the royal entreaties, to confer with Kiffin. The matter is to be regretted; but it is one that implies a want of feeling, not a want of principle.

There is still another case of Penn's mediation which has exposed him to censure. This is the case of Dr Hough, president of Magdalen College, Oxford, afterwards Bishop Hough, "loved and esteemed by all the nation," as Pope has written. Hough, supported by the fellows of his college, would not retire from his presidency at the dictation of the king, to make way for the infamous Parker, Bishop of Oxford. Such compliance would be a violation of their statutes and their oaths. But anxious to conciliate James, the fellows engaged the services of Penn as intercessor on their behalf. "He exhorted the fellows," says Lord Macaulay, "not to rely on the goodness of their cause, but to submit, or at least to temporize." The authority for this statement is a note addressed during the heat of the controversy to Bailey, one of the fellows of Magdalen. The note was without signature, and was not in Penn's handwriting, but Bailey believed it to proceed from him, and he replied to it in a letter addressed to Penn. Both letter and answer were printed, and afterwards, during Penn's life, were frequently reprinted, without calling forth any public contradiction from him. Hence Lord Macaulay concludes that the anonymous epistle containing such discreditable counsel was really the production of Penn. To this it is replied that Penn *did* deny the letter. A contemporary account of the transaction is extant among the papers of Magdalen College, and on the margin of the anonymous letter is written by Hunt, one of the fellows engaged in the conference, the distinct declaration,—"This letter Mr Penn disowned." How he disowned it, whether verbally or by letter, does not appear; but the indorsement made by Hunt seems an authentic contradiction. Having satisfied the parties most nearly interested, Penn might be unwilling for various reasons to resort to a public disavowal. He had completely failed as a mediator, and the king, in his contest with the college, had rendered himself at once odious and contemptible. Silence, therefore, was the euthanasia to be desired.

The conference with the fellows was afterwards resumed at Windsor. On this occasion Penn is charged by

[1] Sir James Mackintosh first inferred that Sunderland's letter was addressed to William Penn. He was ignorant of the existence of George Penne. (For the full discussion of this and other charges against the Quaker legislator, see the *Life of William Penn*, by Mr Hepworth Dixon, new edit., 1856; and Lord Macaulay's *History of England*, edition of 1858.)

Penn Lord Macaulay with having "used a bishopric as a bait to tempt a divine to perjury." The divine was Dr Hough, who, in a letter to a friend, gave the only account we possess of the interview. "I thank God," says Hough, "that he (Penn) did not offer any proposal by way of accommodation; only once, upon the mention of the Bishop of Oxford's indisposition, he said, smiling, 'If the Bishop of Oxford die, Dr Hough may be made bishop. What think you of that, gentlemen?'" And Hough adds, "When I heard him talk at this rate, I concluded he was either off his guard, or had a mind to droll upon us." The drollery was certainly ill-timed and open to misconstruction; but we cannot think that it affords any good basis for a serious accusation. Penn we believe to have been sick of the conference. He knew how utterly fruitless the whole would be; his own views were directed towards a larger measure of toleration; and, tired of the contest, he was glad to escape for a moment from unavailing argument to the shelter of even a poor jest. He had better been absent from both conferences; but the sum of his errors does not amount to criminality. He was credulous and deluded as to the king's intentions; he lived in bad times; and, considering political questions as vastly subordinate to his religious views, he was willing, in order, as he conceived, to promote the latter, and preserve peace, to concede points which his friends Sidney and Locke would have strenuously resisted or unhesitatingly condemned.

In the midst of these difficulties and contentions, Penn issued another theological treatise—*Good advice to the Church of England, the Roman Catholic, and Protestant Dissenters.* The work was an earnest pleading for toleration to all sects, and for the repeal of the Test Act; but it was little regarded. The nation had then entered on that great contest which resulted in the abdication and flight of the king. Penn saw the inevitable tendency of James's measures, and counselled him against the headlong defiant course which lost him his throne, but his efforts had only the effect of increasing the popular suspicion against himself. The infatuated monarch had scarcely crossed the Channel ere Penn was summoned before the lords of council, and obliged to give security, in a sum of L.6000, for his appearance on the first day of next term. When that day arrived there was no charge and no accuser. But in May 1690 Penn was arrested on the grave accusation of holding a treasonable correspondence with the deposed king. James had written to Penn soliciting his assistance and renewing his professions of regard, and the letter, along with others, had been intercepted. Penn's defence was simple and direct. He could not prevent the royal exile from writing to him: he felt towards James a sincere friendship, but he had never thought of restoring him to the throne; and he had not been able to agree with him on state affairs. The new sovereign, William III., would at once have set him at liberty without imposing any conditions, but in deference to some members of council, Penn was required to give bail. Next year a similar charge was preferred against him by an infamous informer named Fuller (afterwards branded by the House of Commons as a cheat, a rogue, and false accuser), and Penn withdrew from public notice. His enemies were numerous and strong: they darkened the very air against him, he said. He retired to his seat in the country (whither he does not seem to have been pursued), and continued there for more than two years. He solaced his forced retirement by literary labour, and produced a series of *Reflections and Maxims,* embodying the experiences of his busy life, and an *Essay towards the Present and Future Peace of Europe,* in which he argued for a great European congress to settle international differences without an appeal to arms. At length, towards the close of 1692, Penn, on an urgent application to the Crown, obtained a public hearing in council, and was fully acquitted of all the charges and suspicions that had so long hung over him. A brighter day seemed at length to be at hand.

A new series of troubles, however, sprung up regarding his American colony—that "Holy Experiment" which lay so near his heart. The success of the French in the war then raging rendered it necessary to strengthen the frontiers, and form one imperial government out of the northern colonies. The separate charter of Pennsylvania would require to be abolished in order to secure military co-operation, and in such a step, however liberally the government might be disposed to act in acquiring the province, the governor saw the destruction of all his long-cherished hopes and plans. The calamity was averted by Penn relinquishing in part his pacific Quaker principles, and agreeing to furnish a contingent of eighty men, with the necessary equipments, during the continuance of the war. The peace of Ryswick afterwards removed this difficulty, and no military organization was attempted. Discontent, however, began to spread in Pennsylvania, and Penn was resolved to proceed once more to his colony. In September 1699 he embarked for America, and arriving in safety at Pennsylvania, continued to reside there for a period of three years. His presence had the effect of appeasing the animosities of rival factions. He renewed and extended his friendly treaties with the natives, and, in conjunction with his council and assembly, arranged another governmental code or charter for the province. In all these transactions—difficult and delicate as many of them, with a mixed body of settlers, must have proved—the justice, benevolence, and generosity of Penn are strikingly apparent. His exertions in the New World were, however, threatened with total destruction at home. A strong effort was made to convert the private into Crown colonies. A Bill of Annexation had been drawn up and brought into the House of Lords; and Penn hastened back to England to vindicate his rights. He was again successful; but other calamities awaited the governor of Pennsylvania. His son, whom he had sent out as his representative to the colony, disgraced his birth, and alienated the affections of the people by flagrant misconduct; and the executors of a crafty steward, whom he had long trusted, preferred against him a claim amounting to L.14,000, at the same time threatening to seize and sell the province if the sum were not immediately paid. The accounts were complicated; a Chancery suit followed; and Penn, acting under legal advice, sought shelter from successful knavery in the Fleet Prison. In this extremity of his fortunes he contemplated the sale of Pennsylvania to the Crown. For the soil and government of the province he asked a sum of L.20,000, with a guarantee that it should remain a separate and distinct colony, and enjoy the free institutions established by its founder. A considerable portion of the settlers had grown lukewarm or hostile to their old benefactor, animated by that grasping and selfish spirit too often the concomitant of young colonies struggling for wealth and power. But Penn remembered the principles on which he had founded his Christian democracy, and still desired to legislate for future generations. The imperial government declined his offer, restricted by the conditions to which he adhered; and Penn was able by the help of friends, to effect a settlement with his rapacious creditors. He was again at liberty, and he retired to a country seat which he had taken in Berkshire. His long confinement in the close atmosphere of the Old Bailey, his griefs, disappointments, and losses, and the pressure of more than threescore years, had seriously impaired his health and vigour. He still corresponded on the affairs of his colony, his latest efforts being directed towards the relief of the poor Negroes. But in 1712 he sustained several shocks of paralysis, and ere the year closed the once active and fertile mind of William Penn was laid in ruins. He lingered

on for nearly six more years, lost to the world, but free from suffering—a child in intellect, and delighting in his children, his fields, and flowers, till death came to his release, July 29, 1718. "The traveller," says a local historian, "in passing from Beaconsfield to the neighbouring village of Chalfont St Giles in Bucks, passes a small inclosure on the right-hand side of the road, known as the Friends' or Jourdan's burial-ground. But though no monumental stone attracts attention, and the sunken graves hidden in the tall grass escape the passing glance of a stranger, it well deserves to be recorded as the resting-place of William Penn, the founder of Pennsylvania." Two of Milton's friends—Thomas Ellwood, who read to the poet in his blindness, and Isaac Pennington—were buried in the same sequestered graveyard. Near it is the cottage in which Milton resided during the prevalence of the plague in London, and where he is supposed, at the suggestion of Ellwood, to have written his *Paradise Regained;* and a few miles off, separated from Chalfont by green lanes and groves of beech and elm, are the last residences and the graves of Waller and Burke. Amidst scenes thus consecrated by genius and patriotism, and rich in natural beauty, the ashes of William Penn—an English worthy of the old simple heroic stamp—have found a fitting place of repose. (R. C—S.)

PENNANT, THOMAS, an eminent naturalist, was born of an old Welsh family at Downing in Flintshire on the 14th June 1726. He acquired the rudiments of his education at Wrexham, and subsequently studied at the university of Oxford. His taste for natural history was first excited by the perusal of Willughby's *Ornithology;* and he had no sooner left Oxford than he set out on an excursion into Cornwall in pursuit of his favourite science. He became a contributor to the *Philosophical Transactions* as early as 1750; and in 1756 was chosen a member of the Royal Society of Upsal on the recommendation of Linnæus. His reputation as a naturalist was established by his *British Zoology*, in one volume folio, in 1761, and subsequently extended to 2, 3, and 4 octavos. He visited the Continent while this work was in the press, and made the acquaintance of Buffon, Pallas, and Haller. He set out for Scotland on a scientific excursion in 1771, and published an amusing account of his tour in three volumes 4to, which passed through several editions. During the same year he published his *Synopsis of Quadrupeds*, afterwards enlarged into a *History of Quadrupeds.* His Welsh tour was published in 1778, and his journey from Chester to London in 1782, in one volume 4to. About the year 1784 appeared his *Arctic Zoology*, a work which, although chiefly a compilation, was very much esteemed. He also published a natural history of the parishes of Holywell and Downing, within the latter of which he had resided during more than fifty years. Not long before his death appeared his *View of Hindustan*, in two volumes 4to, two more volumes being brought out by his son after his death, entitled *Outlines of the Globe.* Pennant died at his seat at Downing in 1798, in the seventy-second year of his age.

PENNISTON, a market-town of England, in the West Riding of Yorkshire, stands on the right bank of the Don, 17 miles S.S.W. of Wakefield, and 175 N.N.W. of London. It is well and regularly built; and contains a parish church, places of worship belonging to Independents, Methodists, and Quakers, a grammar school, and a free school for girls. There are here quarries of paving-stones, coal-pits, and woollen and cotton manufactories. A weekly market and five annual fairs are held at Penniston. Pop. of parish, 6302.

PENNSYLVANIA is central in its position with respect to the original Thirteen States and their territories; New England at the N.E., and the southern states at the S., being equally distant. Later accessions of territory have thrown it eastward and northward of the geographical centre, though it still remains nearly central to the business and population generally. The limits of the state form a nearly perfect rectangular figure, lying between a line at 39. 43. N. Lat. at the S., and one at 42. 15. at the N. The eastern boundary is irregular, following the course of the Delaware River, and at the extreme points reaching to 74. 42. W. Long. The western boundary is a right line at 80. 46. W. Long. The adjacent states are,—New York on the N., New Jersey on the E., Delaware, Maryland, and Virginia on the S., with a part of Virginia and Ohio on the W. At the north-western corner some territory is added, giving a shore-line of 45 miles on Lake Erie; and at the S.E. the state of Delaware extends northward, along a crescent line of 25 miles, into the rectangle. The extreme length of the state is 310 miles, and its width 160 miles, to which last 15 miles are added at the point of contact with Lake Erie. The whole area is 44,400 square miles, or 28,416,000 acres.

The south-eastern part of the state is very little elevated above the sea; but proceeding northward and westward, it soon becomes rough, and finally mountainous, the central part of the state being particularly so. The elevated mass which this mountainous interior presents is cut through by several branches of the Susquehanna and Delaware rivers; yet the most accessible pass for the railroad to Erie is at 1900 feet above the sea, and that of the central railroad to Pittsburg is at 2360 feet. A tunnel here reduces the actual track of the railroad to 2161 feet. Westward of this mountainous centre the surface declines toward the Ohio River and Lake Erie, remaining generally at about 1150 feet elevation, though deeply cut by the Ohio and its tributaries. The bed of the Ohio is at 650 feet above the sea at the point where it leaves the state, and the plain bordering Lake Erie is at nearly the same altitude. Notwithstanding the number of mountain ridges, and the general altitude of the interior and western portions, the surface aspect is usually smooth and well wooded, without the proportion of rocky and precipitous declivities usually found in such uplifted tracks.

The mountains of the state are a section of the great Appalachian chain, and consist of a large number of parallel ridges, which come into the state at the S., on a line from S.W. to N.E., but curve more eastward toward the N., forming crescent lines, and passing into New Jersey and southern New York. This mountainous belt is nearly 200 miles in width, and the ridges on the eastern side are generally more narrow and precipitous than those on the W. These last are the Alleghanies proper, and they are more massive, often with broad summits, and with large areas of arable surface. The ridges at the E. have a share of igneous and altered rocks, but those of the interior and the W. are all made up of rocks of the coal measures, or of rocks just below them. None of the mountains are granitic or volcanic, except some small portion of the South Mountain, the first ridge met from the east. This ridge is about 1000 feet above the sea; and the next inland, called the Blue Mountain or Blue Ridge, is about 1500 feet high,—the first named being interrupted in the interior, and the last named passing entirely through the state from New Jersey into Maryland at the south. West of this, in the coal region, is Broad Mountain; and a constant succession of less distinguished or less continuous ridges occupies the space westward, until, at the most elevated portion, the Bald Eagle, Alleghany, Chesnut, and Laurel ridges of mountains are met. These last named are often near 3000 feet above the sea, and their average is about 2500 feet. There are no single peaks of any note in the state, and the remarkable continuity of the ridges is everywhere characteristic.

The valleys are the complement of the peculiar ridge formation belonging to this chain of mountains, though not so decisively marked as those of Virginia in this respect. The whole arable portion of the interior of the state lies in

the succession of valleys corresponding with the ridges, and in the river valleys cutting through these ridges. The Susquehanna and Delaware cut through the entire belt of ridges; but their tributaries usually drain the valleys in a line at right angles to the two greater rivers. The Cumberland or Appalachian Valley is the principal one in the state, extending entirely through it eastward and southward of the Blue Ridge. The Wyoming Valley is the most important on the north branch of the Susquehanna; and on the west branch the Juniata and Sinnemahoning valleys are examples. West of the mountains the beds of the Alleghany and Monongahela rivers constitute deep and continuous valleys, into which tributaries from the lateral valleys of the Alleghany ridges fall; the most important of which are in Fayette, Somerset, and Indiana counties.

Delaware River forms the eastern boundary of the state, and it is much like the Hudson in its breadth and depth of water for a considerable distance inland. Tide water extends 132 miles from the sea to Trenton, New Jersey; and the river is remarkable for its depth at and below Philadelphia, admitting ships of the largest class. For much of the wharf-line of that city it measures 45 feet in depth. The Delaware rises in New York among the Shawangunk Mountains, and it is navigable for boats for the whole distance after touching Pennsylvania, though partial interruption exists at the Delaware Water Gap, where it breaks through the Blue Ridge, and again where it passes over a ledge of primary rocks at Trenton, New Jersey. Its length is 300 miles. The Susquehanna drains the central portion of the state southward into Chesapeake Bay. This is a rapid river with a rocky bed, and navigable only for floats and lumber within the state, which are sent down it in great quantities at the spring floods. The main stream is 150 miles long below Northumberland. The north branch rises in New York, and has a tortuous course of 250 miles to the point of junction. The west branch rises beyond the Alleghany Mountains, and cuts through them in a very irregular course of 200 miles to Northumberland, the point of junction. The Ohio River drains all the western part of the state, except a small slope to Lake Erie; yet 50 miles only of the river so named lie within it. The Alleghany is its chief branch, rising in the northern county of Potter, and making a curve within the limits of New York, to return southward 150 miles to Pittsburg. It is navigable for steamboats throughout this distance for a part of the year. The Monongahela is the other great branch, rising in Virginia, and running northward, and navigable for steamboats 60 miles. Below their junction the Ohio is usually navigable for large boats, though sometimes failing in summer. The Lehigh and Schuylkill are branches of the Delaware from the west, and of note in the business and history of the state. Both have canals and lockage navigation, and send vast quantities of coal and iron to market. The Lehigh is 90 miles in length, and the Schuylkill 120 miles, passing through Philadelphia just below its entrance into the Delaware. The Juniata is a large branch of the Susquehanna from the west, running through a rich coal and iron region for 150 miles.

Lake Erie is the only lake bordering on or within the state. At this point, which is one-third its length from Buffalo, the lake is clear from ice early, and here is the very superior harbour of Presque Isle, or Erie.

The geological features of the state may be described as being made up of an area of primary rocks of the stratified class, with small veins of granite and intrusions of trap at intervals, covering the south-eastern counties below a line from Easton to Harrisburg and Gettysburg. All these lie at an angle of 30° to 60°, dipping S.E. Next is a belt of gneiss, mica-slate, and the older sandstones, in the like positions. Other altered rocks, with their unaltered associates, in various positions of folding and even of overturned plication and contortion, succeed, in proceeding inland; and following in the ascending series, are the white sandstone, the iron-bearing shales, the valley limestone, and then the slates, limestones, sandstones, and shales of the New York formations. Above these are the conglomerates, and upon these last the coal measures, which, like all below them, present the most extraordinary phenomena of folding, overlapping, and every form of wave-like disturbance. To this disturbance and its attendant alterations the production of the anthracite coal is due. Many faults and dislocations of shale exist here, and the entire body of the coal is deprived of its bitumen. Toward the interior a portion of the coal becomes semi-bituminous, and beyond the Alleghanies it is wholly bituminous. The coal measures cover the whole western portion of the state, sinking all the older geological formations far beneath the surface, the deepest point of the basin being near Pittsburg. The vast bituminous coal basin is little disturbed by geological uplifts, dipping inward and southward; the strata cropping out, however, at the northern line of the state. Toward Lake Erie the descent is rapid over the outcropping strata of the New York shales, the only rocks in this part of the state below the coal, 2000 feet of these being cut through in a descent of 1000 feet to the bed of the lake. The distortion and alteration of the eastern part of the great coal formation of Pennsylvania is the most remarkable geological feature of the state.

The minerals of the state are indicated by its geological character. Coal is first, and iron next, as its natural associate. There are no mines of the precious metals; but copper, zinc, and lead are found in small quantities in the east. Plumbago is also mined. Iron is more extensively made than in any other part of the Union, because of the proximity of rich fossil and hematite ores to the anthracite coal. The entire belt of hilly lands lying next the first high ridges is remarkably rich in all forms of the sedimentary oxides of iron, both the open surface and the lower strata of the primal shales yielding great quantities of these ores; and they are also abundant in the interior and western part of the state. Very valuable iron sandstones are also worked at Danville and in other parts of the interior. The production of iron for three years is here given, the anthracite iron being made in the anthracite coal region, and the charcoal and coke-iron mainly near Pittsburg:—

	Anthracite. Tons.	Charcoal and Coke. Tons.	Total. Tons.
Iron made in 1854	208,703	152,703	361,406
„ 1855	255,326	138,201	393,527
„ 1856	306,966	140,752	447,718

The production of coal is very great. The mines of the anthracite region are remarkable for the great size of the beds, their peculiar and often vertical position, and for the very great facilities they offer for cheap mining on the hillsides, the constant succession of folded strata often bringing thick beds of coal to the very tops of the hills. A picturesque feature of the anthracite region is the machinery for running coal down the hills to the level of rivers and railroads. In the bituminous coal region equal facility of access to the coal beds exists, and much of it is mined from horizontal strata, easily exposed, and opening directly into the river valleys. The quantity of coal mined for recent years is as follows:—

	Anthracite Coal. Tons.	Bituminous Coal. Tons.
1855	6,626,288	1,503,000
1856	7,258,891	1,842,600
1857	6,764,587	(estimated at) 2,000,000

In 1857, 34,000,000 bushels of bituminous coal were shipped to markets on the Ohio River below Pittsburg, or 1,360,000 tons. Valuable beds of cannel coal are worked near Pittsburg for the manufacture of oil, as well as for fuel. Large quantities of marble are produced in various parts of the state; and the recent limestone of the coal

Pennsylvania.

measures, with the blue limestone of the Appalachian valleys, are generally abundant, and largely used as fertilizers after burning. The marble used so much at Philadelphia is from the limestone basin of Montgomery county.

Salt springs are worked on the Monongahela and Beaver rivers. In 1850, 919,100 bushels of salt were made there. Nitrate of potash (saltpetre) has been found in large deposits. Mineral and medicinal springs exist in many parts, generally chalybeate, or but slightly sulphurous, of which the Bedford springs are the most celebrated as a resort. Valuable white sulphur springs exist in a few localities.

The climate of Pennsylvania is marked by the extremes of heat and humidity peculiar to all parts of the United States in that latitude. The yearly mean temperature is 45° on the northern border, and 52° on the southern; the isothermal line of 50° traversing the state somewhat south of its centre. The summer mean is 70° for the central portion, varying from 66° at the highest part of the northern border to 73° at the south. In winter the western part is relatively coldest, the mean for the three months being 30° at Pittsburg, and 33° at Philadelphia. At Philadelphia the most extreme cold observed is 10° below zero, and the greatest heat in the shade 100°. The average of minimum observations for January is 8°, and of maximum temperature in July 93½°. At Pittsburg the coldest point observed is 18° below zero, and the greatest heat 100°. The elevated portions of the interior are colder than the cities named by about 1° for 400 feet of altitude. The quantity of rain falling has an average for the year of 42 to 45 inches for the eastern part of the state, and of 36 inches for the part west of the mountains. In the three months of summer 12 inches fall east of the mountains, and 10 inches west of them. In winter the eastern part has 10 inches, and the western 7, more than half of which falls as snow. In the central and northern parts the snow remains on the ground throughout the winter; but at Philadelphia it rarely lies long. In extreme winters the Delaware is covered with ice. Navigation was closed for weeks in 1856 and 1857; but such instances occur only at remote intervals. The Ohio River is more frequently frozen, and navigation is usually suspended on it for the three winter months. Periods of severe drought are incident to the climate; and periods of excessive humidity also occur, the quantity of rain falling in one summer month sometimes reaching to 12 inches. The winds are generally from the west; but south-east and north-east winds produce great storms, particularly in the eastern part of the state. The climate is, on the whole, a favourable one to energy and health, being less severe than that of the northern states, and free from the unhealthy heats of the states at the south and along the Gulf of Mexico.

The soil is very uniformly fertile, except on the declivities of the mountain ridges. No considerable portion is sandy to excess, as is the case with soils nearer the Atlantic; and most of the arable surface overlies limestone, or is within easy reach of it. Lime is largely used as a fertilizer; and with it clover and wheat have been established and maintained as staple crops. The red clay of the Atlantic border occurs in small quantities in the south-eastern counties; but the soil is generally better, and made up of more diversified elements, than that of the states southward. In the north there are elevated tracts of a somewhat tenacious soil of clay and loam, best fitted for grazing purposes; a belt made up of the northern line of counties being generally of this character. The richest lands are on the many river alluvions, and on the bituminous coal measures in the western part of the state; the last being remarkably productive both in grain and forage crops, and consisting of a deep loam, into the composition of which lime largely enters, by abrasion of rocks at or near the surface. Guano is largely used as a fertilizer near Philadelphia, but not in the western part of the state. Narrow belts of barren magnesian soil exist on the serpentine rocks of the south-eastern counties.

The agriculture of the state is mainly devoted to grain-growing and grazing. Corn and tobacco are largely cultivated,—the second, however, is not cultivated as a leading field crop; while cotton is unknown, and hemp very little cultivated. By the census of 1850 there were 127,577 farms, embracing 8,628,619 acres of land, which quantities would be in 1858 probably 140,000 farms and 9,000,000 acres under cultivation, in consequence of the opening up of new lands. In 1850 the crop of wheat was 15,367,691 bushels; of rye, 4,805,160; of Indian corn, 19,835,214; of oats, 21,538,156; of peas and beans, 55,231; of Irish potatoes, 5,980,732; of buckwheat, 2,192,693; of barley, 165,584; of clover and grass seeds, 178,983; of flax-seed, 41,728 bushels, &c. The grazing products were 39,878,418 lb. of butter; 2,505,034 lb. of cheese; 4,481,570 lb. of wool; 1,872,970 tons of hay. Value of live stock, L.8,645,844; and of slaughtered animals, L.1,712,468. The production of tobacco was 912,651 lb.; of maple-sugar, 2,326,425 lb. The value of orchard fruits was given as L.150,706, and of market products L.143,842. For the year 1858 the increase upon these last sums is very great, raising the last named at least to twice the sum here given.

The manufactures of the state are extensive, particularly in iron and the textile fabrics of wool and cotton. The most recent official statistics are those of the census of 1850, and these are probably nearly correct for the interior of the state, though known to have been imperfectly taken in the great cities, and to be very much below the actual extent of all the manufactures of the state at that time. This census gives the following division of items:—

	No. of Establishments.	Capital.	Hands employed.	Production.
Cotton manufactures.....	208	L.943,525	7663	L 1,108,805
Woollen manufactures ..	380	626,055	5726	1,108,722
Manufactures of pig-iron	180	5,783,005	9294	1,264,898
Manufac. of iron castings	320	713,084	4783	1,115,600
Manufac. of wrought-iron	162	1,631,024	6598	1,921,720

The total for the state of all classes embraced under the head of manufactures, mining, and the mechanic arts, is 21,605 establishments, L.19,682,000 of capital, 127,768 persons employed, and an annual product of L.32,301,000. By researches carefully made at Philadelphia at the close of 1857, it was ascertained that the manufacture of iron in all its forms for that city and its vicinity reached an aggregate value of L.3,000,000 for the year ending July 1, 1857; employing 12,000 workmen. The same investigation showed a production of L.5,000,000 in cotton, woollen, and silk textile fabrics for the same district, employing 20,000 male and female work-people. At Pittsburg alone there was produced in 1857 glass to the value of L.548,330. The leading manufactures other than these are paper, drugs and chemicals, gold-leaf and watches, silver ware and plate, boots and shoes, clothing and hats, plain and morocco leather, glass-ware, brass and brazier's and bolt copper, cabinet and house furnishing wares, soap and candles, carriages, and a large number of classes of useful and fancy goods. These manufactured goods are mainly sold at the south and west, including the West Indies, though many are sent to the northern states and Canada.

The commerce of the state is large and increasing, though several causes have recently concurred to cause foreign importations to come through the port of New York. It is estimated that about L.2,500,000 worth of package dry goods are so imported at New York and Boston for merchants in Philadelphia, and for distribution to the interior from this point. The tonnage for the port

of Philadelphia for the year ending June 30, 1857, was,—tons registered, 59,404; tons enrolled and licensed, 151,976; total, 211,380 tons. The tonnage of the river-port of Pittsburg was 51,061 tons; and of the lake-port of Erie, 10,378 tons. The coasting and coal trades employ much of the tonnage now entered at Philadelphia. A line of Liverpool packets of the first class exists; and an ocean steam line to Liverpool was in operation from 1852 to 1856. The total value of imports at Philadelphia, where all the foreign commerce of the state is carried on, for the year ending July 1, 1857, was,—of free goods, L.428,000; of goods paying duty, L.3,290,850; total, L.3,718,850. The principal articles were,—

Sugar	58,137,504 lb.	L.651,350
Coffee	18,823,714 „	371,410
Molasses	3,137,011 gallons	164,630
Salt	1,101,567 bushels	32,537
Sulphur, soda, and chloride of lime	......	99,830
Copper, lead, brass, and tin	.....	54,685
China and porcelain	....	101,047
Manufactures of wool, and wool and cotton	......	481,255
Manufactures of cotton	....	585,378
Manufactures of silk	....	79,938
Manufactures of linen	......	234,602
Iron, steel, and manufactures of do.	.....	302,314
Raw hides and skins	.....	110,532

The total value of exports to foreign countries for the year ending July 1, 1857, was, for goods the produce of the United States, L.1,451,050; and for goods of foreign origin, L.35,400. The chief articles of export were—

Flour and wheat	L.622,259	Manufactures of iron	L.92,473
Indian corn and meal	184,505	Manufactures of wood	43,741
Pork, lard, and bacon	151,558	Candles and soaps	30,463
Butter and cheese	17,168	Clover-seed	26,754
Beef and tallow	35,800		

The principal trade of the state is not represented in its imports or exports, being with other states of the Union west and south. Dry goods (foreign and domestic), manufactures of iron and other metals, glass, manufactures of leather, chemicals and drugs, and the full supply of all goods, indeed, is taken to the south-western states, mainly from Philadelphia and Pittsburg. Large quantities are also sent northward and coastwise to all parts of the United States. Great quantities of lumber, coal, glass, and iron are carried down the Ohio River from Pittsburg. The lumber trade of the Alleghany River alone for 1857 reached the amount of L.300,166 for lumber sold at Pittsburg, and L.373,080 for that sent by way of the Ohio River to other states. The amount of lumber sent down the Susquehanna River for 1856 and 1857 was about 70,000,000 superficial feet, and its value L.163,000 for each year.

Railroads were constructed as early as 1828 in the coal-mining districts; and they have maintained their prominence among transportation agencies, this state now having a greater aggregate number of miles than any other. At the close of 1857 there were 59 railroads in the state not less than 10 miles in length, and making up an aggregate length of 2500 miles. Their total cost was L.27,000,000. The principal were,—Pennsylvania Central, Philadelphia to Pittsburg, 329 miles; Philadelphia and Reading, 98; Delaware, Sackawanna, and Western, 113; North Pennsylvania, Philadelphia to Bethlehem, 67½; Williamsport and Elmina, 78; Sunbury and Erie, 270 miles—now finished, 40; Lehigh Valley, 46; Catawissa, Williamsport, and Erie, 63½; Alleghany Valley, 176 miles—finished, 44; Northern Central, 138 miles—within the state, 96; Lebanon Valley, 53½. Of the great southern road to Baltimore 19 miles are within the state. The Philadelphia and Newton road, 28 miles, is a part of the great northern line. From Pittsburg there are several great roads leading westward, each about 40 miles in length within the state, as the Pittsburg, Fort Wayne, and Chicago; Pittsburg and Steubenville; and Pittsburg and Connellsville. Within the year ending with June 1858 the sale and transfer of all the state property in lines of internal transportation by canal and railroad has been effected. The Pennsylvania Central Railroad Company purchased the main line of public works, consisting, 1*st*, of two canals, one 181 miles in length, from Columbia to Hollidaysburg, and the other, 101 miles in length, from Johnstown to Pittsburg; 2*d*, of a double-track railroad, 81 miles in length, from Philadelphia to Harrisburg, and 37 miles of railway between Johnstown and Hollidaysburg. For these roads and canals the Central Railroad Company pays L.1,500,000, which sum is added to the cost of that road as given above. The second sale by the state was to the Sunbury and Erie Railroad Company, conveying to them the canals of the north and west branches of the Susquehanna River, four in number, and forming a connected line from the Juniata River to the New York State line along the north branch, and to Farrandsville on the west branch,—a total distance of 167 miles; and also the Delaware division of the state canals, from Bristol to Easton, 60 miles. These canals were sold for L.700,000, both sales by act of the legislature. The remaining canals within the state are the property of private companies. The total length of canals in the state is 1293 miles, of which 921 miles are east of the mountains, and 372 miles west of the mountains. The canals belonging to private companies are as follows:—Schuylkill Navigation, Philadelphia to Port Carbon, 108 miles; Lehigh Navigation, Easton to Stoddartsville, 84; Union Canal, Reading to Middletown and Pinegrove, 99; Susquehanna and Tidewater, Columbia to Havre de Grace, 45; Delaware and Hudson Canal, Howsdale to Hudson River, 25 in the state; Erie Canal, Beaver to Erie, 136; Pennsylvania and Ohio,—portion within the state, 10; Monongahela Navigation, along Monongahela River, 84; Bald Eagle Navigation, at Bellefonte, 25; and Conestoga and Youghiogheny Navigation, 36. The business of these railroads and canals in the coal region is immense. For 1856 the Schuylkill Canal transported 1,275,988 tons of coal, and the Reading Railroad 1,709,692 tons. The Lehigh Canal transported, in 1856, 1,186,230 tons of coal.

The government of Pennsylvania has the simple republican form common to all the States. The legislature consists of a House of Representatives of 100 members, elected annually, and a Senate of 33 members, elected for a term of three years. Both classes are now elected by districts having sometimes two or three representatives each, but after 1864 the constitution requires their election by single districts. The powers of the legislature are liberally construed; it may enact any laws not prohibited by the constitution. In 1776 the colony made many changes in its charter, giving it much of the form of a state constitution; but the first complete state constitution was prepared and adopted by a general convention called for that purpose in 1790. In 1838 the constitution was amended by general convention, and the amendments were adopted by popular vote. In 1850 it was again amended to make the judiciary elective; and in 1857 it was still further amended by restricting the power of the legislature to contract debts beyond the sum of L.150,000, to confer power to repeal corporate enactments, and to require elections to the legislature by single districts. The governor is elected for three years, and has the usual powers and restrictions. He has now no power to appoint judges or magistrates of any grade, except to fill vacancies until the time of the stated election. The judiciary consists of five judges of the Supreme Court, elected for fifteen years; of one president and two associate judges for each Court of Common Pleas, elected for terms of five years each; and of local and municipal magistrates. The Supreme Court and Court of Common Pleas possess many

of the powers of courts of Chancery, and the judges of Common Pleas also hold quarter sessions of the peace, and an orphans' and probate court.

The revenues of the state are derived from various forms of taxation. The townships levy taxes for the support of schools, and for the construction of roads. The counties levy, collect, and disburse the taxes necessary to support the administration of justice in matters confined to themselves. The state levies a direct tax of three mills on a dollar upon all property at the value fixed by assessments; but a still larger sum of its revenues is obtained from special taxes. The following sums were raised in 1857:—

General tax	L.323,890
Canal and railroad tolls	272,825
Tax on bank dividends and corporations	115,517
Tax on tonnage and passengers	42,617
Tax on licenses	80,983
Various special taxes	141,365
Total revenues	L.977,197

The expenditures of the state in 1857 were L.1,126,516. The public debt at the close of 1857 was L.8,308,695; from which sum the sale of the public works in effect takes L.2,200,000, leaving the actual debt L.6,108,695. By the triennial assessments the valuation of all property in the state, real and personal, was as follows:—

Valuation of 1851	L.102,687,506
„ 1854	110,777,315
„ 1857	118,493,800

The religion of the population is chiefly Protestant, though many Catholic churches exist. With the exception of a preponderance of Friends, or Quakers, in Philadelphia and the eastern part of the state, there is nothing to distinguish the religious character of the population as a whole. The principal sects are Methodists, Presbyterians, Lutherans, and Baptists.

The educational system of the state was re-organized and greatly invigorated by the legislature in 1838, which gave the counties power to establish free schools; and again in 1854, when all were required to support free schools. An energetic and well-directed system of teaching and supervision for these free schools is now fully established, with an efficient county and state superintendence. A sum of L.40,000 annually is distributed by the state for the support of these schools, and a larger sum is raised by local tax. The tax levied for school purposes in the year ending June 1, 1857, was L.323,037; and for buildings, L.68,680. Of this there was—

Collected and expended within the year	L.319,733
Received from the state	34,317
Cost of instruction	L.236,949
Cost of fuel, &c.	35,952
Cost of school-houses, &c.	92,559
Total cost, 1856–7	L.365,460

The number of children taught for the same year was 541,247, and the number of teachers 12,475. In all this statement the county of Philadelphia is not included. A system of academies was established previous to the adoption of the free school system, one in each county receiving an appropriation of money from the state; but the appropriations are not continued, and that class of institutions is not well sustained. There are ten flourishing colleges, seven theological schools, four medical colleges, and one law school in the state,—all incorporated, and generally flourishing, though sustained by their own revenues and endowments alone. The university of Pennsylvania at Philadelphia has 12 professors, 129 students, and 1269 alumni. Jefferson college has 10 professors, 222 students, and 1492 alumni. The ten colleges have together 10 colleges, 73 professors, 886 students, 5191 alumni; 7 theological schools, 19 professors, 184 students; 4 medical colleges, 31 professors, 1182 students.

The district bordering on the Delaware River and Bay, which subsequently became the province of Pennsylvania, and its appendage of the three Lower Counties, received its first colony from Sweden. An extensive scheme of colonization for the New World was set on foot in Sweden and Finland nearly at the date of the earliest colonization of New England; and in 1627 a body of Swedes and Finns settled on the Delaware, going as far northwards as the locality of Philadelphia. They made little progress, though a deserving people, and not particularly unfortunate, until visited in a hostile manner by the Dutch from New York in 1655; and submitting without a contest, they passed, with all other possessions of the Dutch, under British rule in 1664. In 1681 the whole district west of the Delaware was granted to William Penn; and in 1682 Penn founded Philadelphia, and planted his colony near it. Under this charter from Charles II. the three Lower Counties were retained under the same governor and proprietor until 1699, when the Lower Counties were granted a separate legislature, though retained under the same governor until the revolution in 1776. The colony planted by Penn was remarkably fortunate in its relations with the Indians. His justice and firmness, with the high character of the body of the colonists, who were all Friends, or Quakers, preserved a peace with them unbroken during the whole colonial period previous to the French war of 1755. Subsequently the original colonists, or Friends, were regarded with uniform kindness by the Indians; though Braddock's defeat and the Wyoming massacre attested the identity of the savage tribes of this colony with others of their race. In the contest of the colonies with the mother country, Pennsylvania bore an active but not an embittered part. The most prosperous of the colonies, and in a central position, it became the seat of the congresses held by the colonies both before and after the decision of the struggle. Franklin, Rush, and Robert Morris represent the moderate yet firm views of Pennsylvania at that time. Independence was proclaimed here; and the seat of the general government of the United States remained here until 1800. A large emigration from Germany settled in the counties near Philadelphia before and subsequent to the revolution, and these have retained their language and national characteristics much longer than like colonies of Germans elsewhere. The defeat of Braddock, and the revolutionary battles of Brandywine and Germantown, with the memorable hardships of Washington's winter encampment at Valley Forge, are prominent historical incidents.

The population is derived from several sources. Traces of the original Swedish colony remain, but the Friends constituted nine-tenths of the population for more than half a century. The large German and Irish emigrations peopled the middle and western parts next, and at the revolution began that indiscriminate interchange of populations which now characterizes all the States. The following statistics are from the enumerations at the several dates of the national census:—Population of Pennsylvania in 1790, 434,373; 1800, 602,545; 1810, 810,091; 1820, 1,049,313; 1830, 1,347,672; 1840, 1,724,033; 1850, 2,311,786.

The classification of the population in 1850 was, 1,142,734 white males, 1,115,426 white females; 25,369 coloured males, and 28,257 coloured females. Thirteen per cent. were of foreign birth: 151,723 in Ireland; 44,260 in England, Scotland, and Wales; 78,592 in Germany; and 4083 in France. Of paupers there were 11,551; 1145 deaf and dumb, 1914 insane, and 1467 idiotic. There were 408,497 families, inhabiting 386,216 dwellings. In 1857 there were returned 603,407 taxables, which number would, at the ratio of former years, place the total population of the state in 1857 at about 3,400,000. (L. B.)

PENNY. See COINAGE.

PENNYWEIGHT. See COINAGE; also WEIGHTS AND MEASURES.

PENOBSCOT, a river in the United States. (See MAINE.)

PENON DE VELEZ, a fortified town of Morocco, belonging to Spain, stands on a lofty rock on the S. side of the Straits of Gibraltar, 80 miles S.E. of Ceuta. It is built in the form of an amphitheatre, with two principal streets; and contains several churches, a bomb-proof magazine, storehouses, and a state prison. It was founded in 1508 by Pedro of Navarre; captured by the Moors in 1522; but recovered in 1664 by the Spaniards, who have since retained it.

PENRITH, a market-town of England, county of Cumberland, in a fertile valley watered by the Eamont and Lowther, which unite about a mile below the town, 17 miles S.S.E. of Carlisle, and 282 N.N.W. of London. It stands at the foot of a hill, on the verge of the county, and of the district called Inglewood Forest. The principal street extends along the road from Kendal to Carlisle; and many of the houses are handsome, most of them being built of red freestone. On a knoll to the W. of the town stand the ruins of the castle, which give to Penrith a very picturesque appearance. It was built by the Nevilles during the wars of the Roses, and dismantled in the civil war by the parliamentary party. The parish church of Penrith is a large and handsome though plain edifice in the Grecian style. It was almost entirely rebuilt in 1722. In the churchyard is a singular ancient monument, called the Giant's Grave, consisting of two pyramidal stones 11½ feet high, and 15 feet distant from each other, which are said to have been set up in memory of a giant named Owen Cœsarius. A new Episcopal church, in the style of the thirteenth century, was built at Penrith in 1850, and forms one of the principal ornaments of the town. There are also places of worship belonging to Independents, Wesleyan Methodists, United Presbyterians, Quakers, and Roman Catholics. The town has several schools, a mechanics' institute, a reading-room, and a savings-bank. To the N. of Penrith is a race-course, on which races take place annually in October; and about a mile from the town, in the same direction, stands a square tower called the Beacon, commanding a beautiful and extensive view. The people of Penrith are chiefly employed in agriculture and weaving; some retail trade is also carried on. Since the opening of the Lancaster and Carlisle Railway, on which Penrith is a station, the place has risen very much in importance; and many handsome new houses and shops have been built. The town is a place of considerable antiquity, and it formerly played a conspicuous part in the border warfare. It was taken by the Scots several times in the fourteenth century, and in 1715 and 1745 was occupied by the insurgents. In the vicinity there are many relics of antiquity; and among the best, King Arthur's Round Table, an inclosed circular area, probably intended for martial exercises, which is called by Sir Walter Scott,

> "Red Penrith's table round
> For feats of chivalry renowned."

Pop. (1851) 6668.

PENRYN, a municipal and parliamentary borough and market-town of England, county of Cornwall, stands on the slope of a hill, in a sheltered, rich, and fertile valley, at the head of a branch of Falmouth harbour, 30 miles S.S.W. of Bodmin, and 266 W.S.W. of London. It consists of one broad main street crossed by other smaller ones; and the principal buildings are the town-hall, market-house, Episcopal church, Wesleyan and Baptist churches, national and grammar schools. Manufactures of paper, woollen stuffs, arsenic, and gunpowder are carried on; and there is a quay between the two branches of Falmouth harbour. Some trade is carried on with the mining district of Redruth; and granite is exported in considerable quantities. Five cattle fairs are held annually at Penryn. The borough unites with Falmouth in sending two members to Parliament. Pop. (1851) 3959.

PENS, PEINS, or PENCZ, GREGOR, a German painter and engraver, was born at Nuremberg about 1500. His knowledge of art was obtained under very favourable circumstances. He first became the pupil of his fellow-townsman Albert Durer. Then having removed to Rome, he softened and refined his style of painting by studying the works of Raphael, and acquired the art of engraving by attending the instructions and aiding the labours of Marcantonio Raimondi. How much advantage he received from these great masters is shown by his numerous prints, which are so well known in England, and by his historical pictures, which are preserved in the galleries of Vienna, Munich, Nuremberg, and Berlin. The death of Pens took place about 1550.

PENS. The word *pen*, in Holy Scripture, refers either to an iron *style* or to a *reed;* the latter being the earliest form of pen used for writing on papyrus with a fluid ink. Reed pens are still in use in the East, and are said to be better adapted to the Arabic character than quill pens. Quills came into use about the fifth century, and continue to maintain their ground, notwithstanding the general employment of metallic pens. The goose furnishes the chief supply, vast flocks being maintained in Russia and Poland for the sake of their quills, of which as many as 27,000,000 have been received in this country in one year from St Petersburg alone. The swan, the crow, the ostrich, the turkey, and other birds occasionally contribute. As there is still a considerable demand for quill pens, a few words on the method of preparing them will not be out of place. The quills, as imported, are tough and soft in texture, and covered with a membrane, so that they will not make a clean slit; the vascular membrane which adheres to the internal surface of the barrel also renders them opaque. These defects are got rid of by the operations of *quill-dressing* or *quill-dutching.* The quills are first sorted into *primes, seconds,* and *pinions.* They are next plunged into hot sand, which causes the interior lining membrane to shrivel up and detach itself from the barrel, and so far loosens the outer membrane that it can be removed readily by scraping with a sharp instrument. The heat also dries up the oily matter of the quill, and renders the barrel transparent, like fine thin horn. By dipping the barrels in dilute nitric acid they become hardened, and acquire a fine yellow tint. In some cases the quills are exposed to the action of steam, and scraped under the edge of a fine instrument, which flattens and apparently spoils them; but they are restored to shape by exposure to a moderate heat.

The first attempt at metallic pens was to arm the points of quill pens with metallic nibs. Pens have also been constructed of horn, tortoise-shell, and glass. Small pieces of precious stones, such as the diamond and the ruby, have been embedded in the points of horn and tortoise-shell pens by pressure. Thin pieces of gold or other metal have also been attached to tortoise-shell. Nibs of ruby set in fine gold have also been employed; and to prevent injury to the points, the ink-stand was lined with india-rubber. Dr Wollaston constructed pens with two flat slips of gold placed at an angle, and tipped with rhodium. Messrs Wiley of Birmingham have pens of gold, palladium, gold and silver, and silver, pointed with the native alloys of iridium and osmium. Such pens have the advantage of presenting the writing always of the same character and of not being corroded by the ink; they are, however, too costly for common use.

Steel pens were introduced about the year 1803; but many of the improvements which led to their present ex-

tensive use were introduced by Mr Gillott of Birmingham and by Mr Perry of London. Birmingham is the chief seat of the manufacture; the steel is rolled for the purpose at Sheffield into thin sheets, and these are cut into strips about three feet long and four inches broad. After annealing, the scales are removed by pickling in dilute sulphuric acid, when the strips are again rolled to the required thickness. From these strips *blanks* or *flats* are cut out by means of a stamping-press, the fibres of the steel being made to take the direction of the length of the pen. After this the hole which terminates the slit is pierced, and the superfluous metal is removed. The blanks are now annealed in a muffle, and the maker's name is stamped on each blank by means of a small punch. The next operation is to make the flaps concave for nib-pens, and to form the barrel for barrel-pens: this is done at a stamping-press with an appropriate bed and punch. The pens are next inclosed in an iron box raised to a red heat, and quenched in oil, which hardens them. The adhering oil is got rid of by agitating the pens in a tin-plate barrel. They are tempered at a moderate heat, and are placed in a revolving cylinder with sand, which restores the natural colour of the steel. The nib is next ground upon a small emery wheel, after which the slit is made by means of a chisel with a flat side fixed to the bed of a press, the descending screw of which has a cutter which accurately corresponds with the chisel. The pens are coloured brown or blue by placing them in a revolving cylinder over a charcoal fire, and removing them as soon as the film of oxide of the desired colour is formed. A gloss is given to them by immersing them in a solution of lac in naphtha, after which they are dried by heat, counted, and made up in boxes. Steel pens are liable to be corroded by the ink, a defect which does not apply to the pens of thin laminated zinc recently introduced. Pens have also been formed of the new metal aluminum, and pen-holders have been made of the same light material, which, however, is too costly for such common applications.

Pens have been made of vulcanized india-rubber, the ingredients for which are first rolled out in a thin sheet of the thickness of a strong quill, then cut into strips of the width suitable for pens, next heated between two surfaces of glass, one convex and the other concave, and raised in the course of six hours from the temperature of 230° to 305°. This effects the combination of the ingredients, and gives a permanent form to the semi-cylinders, which are made into lengths, and formed into pens by appropriate cutting instruments.

Numerous patents are taken out every year for pens, pen-holders, lead-holders, and pencil-cases; so numerous, indeed, that a list of them for the last few years would occupy considerable space. Purchasers are fond of novelty; and novelty, however slight, is sure to claim the protection of a patent. It is not creditable to our inventive skill that in so copious a patent list so very small a number of inventions should retain a permanent hold on the public. (C. T.)

PENSACOLA, the capital of Escambia county, in the state of Florida, North America, stands on the W. shore of Pensacola Bay, about 10 miles from the Gulf of Mexico, and 64 E. from Mobile. The harbour is safe, but admits only vessels of light draught. The town is regularly built; and contains several churches, a market-house, court-house, and custom-house. About 6 miles below the town, and 5 from the entrance of the harbour, is a U.S. navy station, covering nearly 80 acres of ground, and surrounded by a high brick wall. Pop. of town (1850) 2164.

PENSACOLA BAY, an inlet of the Gulf of Mexico, at the mouth of the Escambia River, is about 27 miles in length by 12 in extreme breadth.

PENSIONARY, or PENSIONER, a person who has an appointment or yearly sum, payable during life, by way of acknowledgment, and charged on the estate of a prince, company, or particular person. At the universities of Cambridge and Dublin the term *pensioner* is applied to those students who live at their own expense, and who are at Oxford called *commoners*.

The term *Grand Pensionary*, was formerly applied to the first minister of the states of Holland, and the first minister of the regency of each city in that kingdom was called a *Pensionary*.

PENSHURST, a village of England, county of Kent, on the Eden, near its confluence with the Medway, 6 miles W.S.W. of Tunbridge. It has a fine old church with many interesting monuments, a Baptist chapel, and two national schools. In the vicinity is an ancient mansion called Penshurst Place, the birthplace of Sir Philip Sidney and Algernon Sidney. Manufactures of paper are carried on; and there are stone quarries in the neighbourhood. Pop. 1628.

PENTACHORD, a musical scale consisting of five conjunct diatonic degrees. Also an instrument of five strings, according to Martianus Cappella and other writers. Julius Pollux ascribes its invention to the Scythians.

PENTAGON. See GEOMETRY.

PENTAMETER (πέντε, *five*, μέτρον, *a measure*), a peculiar kind of verse, consisting, as the name implies, of five feet or metres. The first and second feet may be either dactyls or spondees; the third is always a spondee; and the two last anapests. A pentameter line subjoined to an hexameter constitutes what is called *elegiac* verse. Numerous specimens of this verse are to be found among the Greek and Latin classics. Callinus, Tyrtæus, Mimnermus, Theognis, and Solon, in Greece; and Catullus, Propertius, Tibullus, and Ovid, in Rome, were the most celebrated of the ancient elegiac writers. Goethe and Schiller have attempted the introduction of this species of versification into German poetry; and the characterization of the hexameter and pentameter distich by the latter poet is well known through Coleridge's version :—

> "In the hexameter rises the fountain's silvery column,
> In the pentameter aye falling in melody back."

PENTATEUCH (Πεντάτευχος, from πέντε, *five*, and τεῦχος, *a volume*) is the title given to the five books of Moses,—viz., GENESIS, EXODUS, LEVITICUS, NUMBERS, and DEUTERONOMY. The division of the *Book of the Law* (ספר התּוֹרָה), as the Jews called the Pentateuch, into five books is alluded to in the works of Josephus and Philo. It seems that this division was first made by the Alexandrian critics. In Jewish writers are found statements indicating that the Pentateuch was formerly divided into seven portions (comp. Jarchi, *ad Proverb.* ix. 1; *ibique* Breithaupt). In the Jewish canon the Pentateuch is kept somewhat distinct from the other sacred books of the Old Testament, because, considered with reference to its contents, it is the book of books of the ancient covenant. It is the basis of the religion of the Old Testament, and of the whole theocratical life. The term *law* characterizes the principal substance of the Pentateuch, but its real kernel and central point is the foundation of the Jewish theocracy, the historical demonstration of that peculiar communion into which the God of heaven and earth entered with one chosen people, through the instrumentality of Moses; the preparation for, and the development of, that communion; the covenant relation of Jehovah and Israel, from its first rise down to its complete termination.

In considering the Pentateuch, the first question which arises is—Who was its *author?* It is of great importance to hear, first, what the book itself says on this subject. The Pentateuch does not present itself as an anonymous production. On the contrary, it speaks most clearly on this subject. According to Exod. xvii. 14, Moses was commanded by God to write the victory over the Ama-

Pentateuch lekites *in the book* (בספר). This passage shows that the account to be inserted was intended to form a portion of a more extensive work, with which the reader is supposed to be acquainted. It also proves that Moses, at an early period of his public career, was filled with the idea of leaving to his people a written memorial of the Divine guidance, and that he fully understood the close and necessary connection of an authoritative law with a written code. It is therefore by no means surprising that the observation repeatedly occurs, that Moses wrote down the account of certain events (Exod. xxiv. 4, 7; xxxiv. 27, 28; Num. xxxiii. 2). Especially important are the statements in Deut. i. 5; xxviii. 58. In Deut. xxxi. 9, 24, 30, the whole work is expressly ascribed to Moses as the author, including the poem in Deut. xxxii. It may be made a question whether the hand of a later writer, who finished the Pentateuch, is perceptible from ch. xxxi. 24 (comp. xxxiii. 1, and xxxiv.), or whether the words in xxxi. 24–30 are still the words of Moses. In the former case we have two witnesses, viz., Moses himself, and the continuator of the Pentateuch; in the latter case, which seems to us the more likely, we have the testimony of Moses alone. Modern criticism has raised many objections against these statements of the Pentateuch relative to its own origin. Many critics suppose that they can discover in the Pentateuch indications that the author intended to make himself known as a person different from Moses. The most important objection is the following,—that the Pentateuch, speaking of Moses, always uses the third person, bestows praise upon him, and uses concerning him expressions of respect. The Pentateuch even exhibits Moses quite objectively in the blessing recorded in Deut. xxxiii. 4, 5. To this objection we reply, that the use of the third person proves nothing. The later Hebrew writers also speak of themselves in the third person. We might adduce similar instances from the classical authors, as Cæsar, Xenophon, and others. The use of the third person, instead of the first, prevails also among oriental authors. In addition to this we should observe, that the nature of the book itself demands the use of the third person, in reference to Moses, throughout the Pentateuch. This usage entirely corresponds with the character both of the history and of the law contained in the Pentateuch. By the use of the word I, the objective character of this history would have been destroyed, and the law of Jehovah would have been brought down to the sphere of human subjectivity. If we consider that the Pentateuch was destined to be a book of Divine revelation, in which God exhibited to his people the exemplification of his providential guidance, we cannot expect that Moses, by whom the Lord had communicated his latest revelations, should be spoken of otherwise than in the third person. In the poetry contained in Deut. xxxiii. 4, Moses speaks in the name of the people, which he personifies and introduces as speaking. The expressions in Exod. xi. 3, and Num. xii. 3 and 7, belong entirely to the context of history, and to its faithful and complete relation; consequently it is by no means vain boasting that is there expressed, but admiration of the Divine mercy glorified in the people of God. In considering these passages, we must also bear in mind the far greater number of other passages which speak of the feebleness and the sins of Moses.

It is certain that the author of the Pentateuch asserts himself to be Moses. The question then arises, Whether it is *possible* to consider this assertion to be true—whether Moses *can* be admitted to be the author? In this question is contained another, viz., Whether the Pentateuch forms such a continuous whole that it is possible to ascribe it to one author? This question has been principally discussed in modern criticism. In various manners it has been tried to destroy the unity of the Pentateuch, and to resolve its constituent parts into a number of documents and fragments. Eichhorn and his followers assert that GENESIS only is composed of several ancient documents. This assertion is still reconcileable with the Mosaical origin of the Pentateuch. But Vater and others allege that the whole Pentateuch is composed of fragments; from which it necessarily follows that Moses was not the author of the whole. Modern critics are, however, by no means unanimous in their opinions. Ewald, in his history of the people of Israel (*Geschichte des Volkes Israel*, vol. i., Göttingen 1843), asserts that there were seven different authors concerned in the Pentateuch. On the other hand, the internal unity of the Pentateuch has been demonstrated in many able essays. The attempts at division are especially supported by an appeal to the prevailing use of the different names of God in various portions of the work; but the arguments derived from this circumstance have been found insufficient to prove that the Pentateuch was written by different authors. The inquiry concerning the unity of the Pentateuch is intimately connected with its *historical character*. If there are in the Pentateuch decided contradictions, or different contradictory statements of one and the same fact, not only its unity, but also its historical truth, would be negatived. On the other hand, if the work is to be considered as written by Moses, the whole style and internal veracity of the Pentateuch must correspond with the character of Moses. Considerate critics, who are not under the sway of dogmatic prejudices, find that the passages adduced to prove that the Pentateuch was written after the time of Moses by no means support such a conclusion; and that a more accurate examination of the contents of the separate portions goes to demonstrate that the work originated in the age of Moses.

The general arguments for and against the authenticity of the Pentateuch which remain to be considered are the following:—

1. The history of the art of writing among the Hebrews has often been appealed to in order to disprove the authenticity of the Pentateuch. It is true that in our days no critic of good repute for learning ventures any longer to assert that the art of writing was invented subsequent to the Mosaical age (Ewald's *Geschichte des Volkes Israel*, p. 64, sq.); but it is questioned whether the Hebrews were acquainted with that art. It is said that a work of such extent as the Pentateuch was beyond the means of the primitive modes of writing then existing. But various testimonies, not merely in the Pentateuch itself, but also derived from other sources, from the period immediately subsequent to that of Moses, prove that a knowledge of the art of writing was widely diffused among the Hebrews (comp. Judges viii. 14). And if there was any knowledge of this art, its application would entirely depend upon the particular circumstances of a given period. Some writers seem to entertain the opinion that the materials for writing were yet, in the days of Moses, too clumsy for the execution of larger works. This opinion is refuted by the fact, that the Hebrews became acquainted, just in the Mosaical period, with the use of very good materials for writing, such as papyrus, byssus, parchment, &c. (comp. Herodotus, v. 58.) There are, indeed, mentioned in the Pentateuch some more solid materials for writing, such as tables of stone (Exod. xxiv. 12; xxxi. 18; xxxiv. 1, &c.); but this does not prove that in those days nothing was written except upon stone. Stone was employed, on account of its durability, for specific purposes.

2. The language of the Pentateuch has also been the subject of many discussions. It has frequently been urged that it differs less from that of the later books of the Old Testament than might have been expected if this work proceeded from Moses. In this objection the characteristic stability of the oriental languages has been overlooked. The oriental languages are not, in the same degree as the

occidental, in a state of development and constant change. It is also overlooked that the Pentateuch itself, by its high authority, exerted a constant influence upon the whole subsequent religious literature of the Hebrews. And we do not know any other literature of the ancient Hebrews except the religious. In addition to this, we must observe that, nevertheless, the style of the Pentateuch has its distinctive features of antiquity. It contains, for example, a number of characteristic *grammatical formations;* it contains also *words* which do not occur in the other parts of the Old Testament; as well as certain characteristic *phrases* peculiar to the style of that time. Others have vainly endeavoured to find in the Pentateuch, and especially in Deuteronomy, vestiges of a later style. The instances produced by the opponents of the Mosaical origin of the Pentateuch do not stand examination, and are therefore unable to counterbalance the weight of argument deducible from the antique expressions in the Mosaical writings.

3. The historical contents of the Pentateuch are of very great importance in our present inquiry, because they constantly bear testimony in favour of its age and authenticity, and lead to the following important results:—We find, in later times, no period which we could deem capable of producing the Pentateuch as a whole: for this reason, the opponents of its authenticity are obliged to ascribe the different portions of the work to widely different periods. If we allow that the apostles were such persons as they assert themselves to be, we must admit also that the very frequent apostolical allusions to the Pentateuch are a high sanction to the work; and we cannot overlook the fact, that every opinion which, with greater or less decision, finds in the Pentateuch a work of fraud, enters into an unavoidable conflict with the New Testament itself.

In the remote times of Jewish and Christian antiquity, we find no vestiges of doubt as to the genuineness of the Mosaical books. The Gnostics, indeed, opposed the Pentateuch, but attacked it merely on account of their dogmatical opinions concerning the Law, and Judaism in general; consequently they did not impugn the authenticity, but merely the Divine authority of the Law. Heathen authors alone, as Celsus and Julian, represented the contents of the Pentateuch as being mythological, and paralleled them with pagan mythology. In the middle ages, but not earlier, we find some very concealed critical doubts in the works of some Jews—as Isaac Ben Jasos, who lived in the eleventh century, and Aben Ezra. After the Reformation, it was sometimes attempted to demonstrate the later origin of the Pentateuch. Such attempts were made by Spinoza, Richard Simon, Le Clerc, and Van Dale; but these critics were not unanimous in their results. Against them wrote Heidegger (*Exercitationes Biblicæ,* i. 246, sq.); Witsius (*Miscellanea Sacra,* i. 103, sq.); and Carpzov (*Introductio,* i. 38, sq.) In the period of English, French, and German deism, the Pentateuch was attacked rather by jests than by arguments. Attacks of a more scientific nature were made about the end of the eighteenth century. But these were met by such critics as John David Michaelis and Eichhorn, who energetically and effectually defended the genuineness of the Pentateuch. These critics, however, on account of their own false position, did as much harm as good to the cause.

A new epoch of criticism commences about the year 1805. This was produced by Vater's *Commentary* and De Wette's *Beiträge zur Einleitung in das Alte Testament.* Vater embodied all the arguments which had been adduced against the authenticity of the Petateuch, and applied to the criticism of the sacred books the principles which Wolf had employed with reference to the Homeric poems. He divided the Pentateuch into fragments, to each of which he assigned its own period, but referred the whole generally to the age of the Assyrian or Babylonian exile. Since the days of Vater, a series of the most different hypotheses has been produced by German critics about the age of the Pentateuch, and that of its constituent sections. No one critic seems fully to agree with any other; and frequently it is quite evident that the opinions advanced are destitute of any sure foundation—that they are quite arbitrary, and produced by merely subjective motives. We will illustrate this by a few examples relative to the Pentateuch as a whole.

Schumann makes Ezra the author of the law. According to A. T. Hartmann, the separate portions of the law sprang up gradually, some of them as late as the exile; but he does not show by what circumstances they were combined into a whole. According to Dr Ammon, the Pentateuch was planned by Moses; was gradually continued down to the times of Solomon; was entirely forgotten during the period of idolatry; was re-discovered under the reign of Josiah; and was then re-touched, and edited under the name of Moses. Von Bohlen urges the fact mentioned in the Second Book of Kings (ch. xxii.) as if it were explanatory of the origin of Deuteronomy; but he considers some portions to be of a much later origin. He asserts that the Pentateuch was partly written after the exile, that it was gradually developed, and was brought to a conclusion in the age of Christ. According to the latest statements of De Wette, in his *Einleitung in das Alte Testament,* § 157, sq., the ELOHIM portions were written in the age of Samuel and Saul, the JEHOVAH portions nearly about the same period, but Deuteronomy much later, under Josiah. Ewald assigns seven authors to the Pentateuch, who, however, wrote in very different periods. The first, he supposes, wrote in the days of Samson; the second in the reign of Solomon; the third in the reign of Elijah, &c.

The critical doubts respecting the authenticity of the Pentateuch have produced in modern times several works in defence of its genuineness; such as Kanne's *Biblischer Untersuchungen,* 2 vols., 1820; the observations by Jahn, Rosenmüller, and Bleek; Ranke's *Untersuchungen über den Pentateuch,* 2 vols.; Hengstenberg's *Beiträge zur Einleitung,* vols. 2 and 3; Hävernick's *Einleitung in das Alte Testament,* vol. 1; Drechsler, *Ueber die Einheit und Authentie der Genesis;* König's *Alt-testamentliche Studien,* 2d number; Sack's *Apologetik,* &c.

The most important commentaries and exegetical aids for the explanation of the whole Pentateuch, and its constituent parts, are the following:—Calvini Bonfrerii *Pentateuchus Commentario Illustratus,* 1625; Marckii *Commentarius in præcipuas quasdam Pentateuchi partes,* 1721; Clerici *Commentarius,* 1710; Gerhardi *Commentarius in Genesin,* 1693; Merceri *Commentarius in Genesin,* 1593; Vater, *Commentar über den Pentateuch,* 1802, sq., 3 vols.; Rosenmulleri *Scholia,* 3d ed., 1821, sq.; Schumann, *Pentateuchus Hebraice et Græce,* tom. 1, 1829; Von Bohlen, *Die Genesis übersetzt und erklärt,* Königsberg, 1825; Tiele, *Das erste Buch Mosis,* &c., 1st vol., 1836; Tuch, *Commentar über die Genesis,* 1838, &c. The following are the principal English works on the Pentateuch:—Ainsworth, *Annotations on the Five Books of Moses,* 1699; Kidder, *Commentary on the Five Books of Moses,* 1713; Parker, *Bibliotheca Biblica,* 1720, 1735; Jamieson, *Critical and Practical Exposition of the Pentateuch,* 1748; Robertson, *Clavis Pentateuchi,* 1770; Graves, *Lectures on the Pentateuch,* 1815; *The Pentateuch and its Assailants,* by Dr W. T. Hamilton, 1852; *Commentary on the Pentateuch,* by G. Townsend, 2 vols., 1849. There are English translations of the following German works on the Pentateuch. *On the Genuineness of the Pentateuch,* by E. W. Hengstenberg, 2 vols., 1847; an *Historico-Critical Introduction to the Pentateuch,* by H. A. Ch. Hävernick, 1850; and an *Historical Introduction to the Old Testament,* by H. A. Ch. Hävernick, 1852.

PENTATHLON (πέντε, *five*, and ἆθλον, *the prize of contest*), signifies properly the contest of the five exercises, and was a general designation given to the five Grecian games of leaping, running, throwing the discus, throwing the spear, and wrestling. This is the order in which, according to Böckh, these games followed each other in the pentathlon. This was considered, after the *pancratium*, the most beautiful of all athletic performances. It was called by the Romans *quinquertium*.

PENTECOST (Πεντηκοστή, *fiftieth*) is the name given in the New Testament to the "Feast of Weeks," or of "Ingathering," which was celebrated by the Jews on the *fiftieth* day from the festival of the Passover; or seven weeks from the 16th day of Nisan. It was a feast of thanksgiving for the harvest, and commenced immediately after the Passover. It was one of the three great yearly festivals in which all the males were required to appear before God at the place of his sanctuary. Josephus states that in his time great numbers of Jews resorted from every quarter to Jerusalem to keep this festival. (*Antiq.* xiv. 13, 4; xvii. 10, 2; *De Bell. Jud.* ii. 3, 1.) This testimony affords corroboration of Acts ii. 1, 9–11; xx. 16; 1 Cor. xvi. 8, in which the same fact appears. The commencement of the Christian church on the day of Pentecost attached a peculiar interest to this season, and it was established as one of the great festivals in the fourth century. This day became one of the three baptismal seasons (Tertull. *De Baptis.* c. 19; Hieron. *in Zach.* xiv. 8); and it derives its name of Whitsunday, or white-Sunday, from so many being clad in *white* on this the day of their baptism.

PENTLAND FIRTH, a channel separating the Orkney Islands from the coast of Caithness, and joining the North Sea and the Atlantic. It is about 17 miles long from E. to W., and 6 or 8 broad. At the eastern extremity, 4 miles N.E. of Duncansby Head, are the Pentland Skerries, two islands, the largest of which has a lighthouse, with two fixed lights. The depth of the strait varies from 10 to 40 fathoms; and the current runs strongly to the E., with a velocity from 4 to 9 miles an hour.

PENTLAND HILLS, a range of hills in Scotland, in the counties of Edinburgh, Peebles, and Lanark, extending from the distance of 4½ miles S. by W. of Edinburgh for about 16 miles in a S.W. direction. They consist of porphyry, with boulders of granite and gneiss; are partially cultivated, and afford good pasture for sheep. The highest summit is East Carnethy Hill, near the middle of the range, 1878 feet above the sea.

PENUMBRA (*pene*, almost, *umbra*, a shade) is a partial shade observed between the perfect shadow and the full light in an eclipse. As long as any part of the sun is visible during a solar eclipse, the observer is in the *penumbra*, and not in the *umbra* or shadow.

PENZA, a government of European Russia, lying between N. Lat. 53. and 54., E. Long. 42. 20. and 45. 20. It is bounded on the N. by the government of Nijni-Novgorod, E. by that of Simbirsk, S. by that of Saratov, and W. by that of Tambov. Length from E. to W., 170 miles; greatest breadth, 145; area, 14,670 square miles. The surface is generally flat, or slightly undulating; and is crossed by low ranges of hills, which in the S. form the watershed between the Volga and the Don. Numerous rivers water the country; but of these none are of any size or importance, except the Sura and the Moksha, both affluents of the Volga,—the latter rising in this government, and the former in that of Saratov. There are also several small lakes. The soil is fertile, producing corn, hemp, flax, potatoes, and fruit. The extent of arable land in the government in 1849 was 3,962,008 acres; of meadow land, 1,251,249 acres; of wood, 3,645,551 acres; and of waste land, 389,029 acres. There were produced in the same year 39,182,368 bushels of corn, and 1,569,186 bushels of potatoes. The climate is healthy, and the summers are mild and temperate; but severe cold is frequently experienced during the winter. Great attention is paid by the inhabitants to the raising of cattle, sheep, and especially horses; and large quantities of bees are kept. Penza contained in 1849, 291,994 horses, 205,500 horned cattle, 494,314 sheep, and 190,348 swine. The principal mineral production of the government is iron, of which there are mines in the vicinity of Troitzk. Mill-stones are also quarried; and sulphur and vitriol are obtained. There are few large manufacturing establishments; but the peasants in their cottages spin flax and hemp, weave large quantities of coarse linen and woollen cloth, and prepare articles of other kinds for their own use. There are, besides, blast-furnaces and iron-works, soap-works, glass-works, tanneries, and distilleries, all of which, especially the last, are both numerous and large. The trade is chiefly carried on by land, especially with Nijni-Novgorod. Annual fairs and markets are held at various places in the government. The principal exports are corn, flour, honey, wax, brandy, soap, timber, wool, leather, blankets, carpets, and potash. In respect of education, Penza is under the university of Kasan; but the schools are neither numerous nor good. The only printing-press in the government is entirely under the control of the Crown. There are about 600 churches, 11 of which are cathedrals, several convents, and about 70 Tartar mosques. The government is divided into 10 circles, and contains 1,058,444 inhabitants:—

	Pop.		Pop.
Penza	93,371	Nijni-Lomov	112,282
Insara	136,157	Kerensk	83,246
Saransk	112,620	Mokshansk	86,072
Narovchat.	87,558	Gorodischtche	116,151
Chembar	113,136	Krasnosslobodsk	117,851
Total			1,058,444

The most of the people belong to the Greek Church; but there are also 41,210 Mohammedans, and a few Jews and Roman Catholics.

PENZA, the capital of the above government, stands at the confluence of the River Penza with the Sura, 210 miles S.S.E. of Nijni-Novgorod, and 465 S.E. of Moscow. It occupies a beautiful situation on a hill, and is in a great part built of wood, having numerous gardens within its precincts. Among its many churches there is a large stone cathedral. It has several schools and benevolent institutions, the residences of the civil governor and of the Bishop of Penza and Ssaranssk, &c. Tanning, soap-making, weaving, and silk-making are carried on here; and there are large magazines for corn and salt. An active trade is carried on in corn; and an annual market is held (from June 25 to July 4), at which about L.9000 worth of goods is sold. In front of the town is a fine park, with an orchard and a school of agriculture. Pop. (1851) 22,723.

PENZANCE, a municipal borough and market-town of England, in the county of Cornwall, stands on the N.W. shore of Mounts Bay, 24 miles S.W. of Truro, and 281 W.S.W. of London. It is the most westerly town in Great Britain, and is beautifully placed along the curving shore, encircled by rocky eminences. The principal streets, four in number, meet in the market-place; they are for the most part but ill paved, and lined with mean houses. The town-hall is a handsome building of granite in the Grecian style, surmounted by a cupola. There are two Episcopal churches, one of which, recently built, is a fine granite edifice, in the early English style, containing a pulpit made of a single block of granite. The town also contains places of worship belonging to Methodists, Independents, Baptists, Roman Catholics, and Jews. The Royal Geological Society of Cornwall has its head-quarters here, where there is a museum with a valuable collection of minerals. There

is also here a natural history and antiquarian society, an agricultural society, a literary institution, and a public library. The town has a custom-house, and a pier 600 feet long, with a lighthouse at the end. The harbour, however, is only suitable for small vessels. The trade of the place is considerable: tin, copper, china clay, and fish, being exported; while iron, timber, hemp, hides, and tallow are the chief articles of import. Fishery is actively carried on in Penzance, pilchards being the fish chiefly obtained; and there are here tanneries and smelting-houses for tin. The climate of Penzance is extremely mild, and much less variable than that of London. The mean temperature of summer is 60°·5., and of winter 44°·66. Markets are held twice a week, and there are three annual fairs. The number of vessels registered at the port in 1857 was 81, aggregate tonnage 7299. In the same year there entered the port 733 sailing-vessels, tonnage 45,338; and 72 steamers, tonnage 23,042: and there cleared 221 sailing-vessels, tonnage 14,092; and 1 steamer, tonnage 32. The environs of the town are very beautiful; and many interesting remains are to be seen in the neighbourhood. A curious custom is observed in Penzance on the 23d and 28th of June, which is supposed to be a remnant of the ancient sun-worship practised at the summer solstice. After burning a number of tar barrels in conspicuous places, they dance about with blazing torches, and on the following day festivities of a more quiet character are celebrated. Penzance was destroyed by the Spaniards in 1695, and was afterwards sacked by the parliamentary party under Fairfax in 1646. Sir Humphry Davy was born here in 1778. Pop. (1851) 9214.

PENZING, a town of Lower Austria, on the Wien, 3 miles W. of Vienna. It contains many fine villas, a parish church, barracks, and a bathing establishment. Cotton and silk stuffs are manufactured. Pop. 4135.

PEPIN D'HERISTAL, surnamed *Le Gros*, the ancestor of the Carlovingian line of French kings, became "Mayor of the Palace" in 679, and in that capacity was virtually the head of the Frankish monarchy till his death in 714. (See FRANCE.)

PEPIN, surnamed *Le Bref*, or "The Short," was the first king of France of the Carlovingian dynasty, and grandson of the preceding. Having been installed in the hereditary office of "Mayor of the Palace," he dethroned Childeric III. in 750, and caused himself to be consecrated king in 752. He died in 768, leaving the crown to his son Charlemagne. (See FRANCE.)

PEPLUM, or PEPLUS, was a large full robe or shawl worn by Grecian women, and was much larger than either the *chlamys* or *pallium*, as well as finer and thinner than the latter. It was without sleeves, and was fastened by a clasp. It was worn above the common dress, and fell in rich folds around the person, sometimes, in the case of women of rank, trailing upon the ground, as alluded to by Homer, in his epithet of "trailing-the-robe" (ἑλκεσίπεπλος), applied to the Trojan ladies. (*Il.* vi. 442.) The peplum was occasionally used to veil the head. It was the most costly and ornamental of all the productions of the loom, and the art of manufacturing it was entirely oriental. The peplum was the robe of state of Minerva at Athens, with which her statue was solemnly invested every five years at the panathenæa.

PEPPER, the English name of a genus of tropical plants, and also of the fruit which is used as a condiment. The most important of these is black pepper, the dried ripe berries of *Piper nigrum* (Linn.), Nat. Ord. *Piperaceæ*, a shrubby, climbing plant, which has for ages been cultivated in India. It has been introduced into the West Indies, tropical Africa, and South America, where it succeeds admirably. The earliest mention of pepper is by Hippocrates, who employed and recommended it as a medicine. Pliny refers to it as a condiment; but it is doubtful if he could have referred to the true pepper, as he declares that it has neither strength nor taste to recommend it.

The short spike-shaped clusters of berries are produced in great abundance, and when ripe the berries resemble those of our common holly in size and colour, but they lose their bright scarlet colour and smoothness in drying, and become wrinkled and black. In this state we receive them, and they are ground into the coarse grey powder known at table as *black pepper*. *White pepper* is the produce of the same plant, but in order to manufacture it, the black wrinkled coats of the seeds are removed by soaking and friction; they are then somewhat smaller, perfectly spherical, and of a light drab colour. It is ground to powder, and used in a similar manner, and is by many preferred in consequence of its apparently superior appearance, but it loses both strength and flavour by the manipulation. *Long pepper* is the produce of a distinct species, the *Piper longum* of Linnæus, or *Chavica Roxburghii* of Miquel, a native of the Circar Mountains, where it is gathered in its wild state. It is also cultivated in some parts of India. The time for gathering it is just before ripening, when the fruits are very small, and are compactly pressed together upon a small cylindrical spike, which, with the fruit, is about an inch and a half in length, and a little thicker than a quill: when dried it is of a light greyish colour. We receive it from Bengal; but the quantity imported is inconsiderable, as its qualities are analogous to those of white pepper. It enters into certain medicinal preparations, and is a favourite in some culinary operations, particularly the manufacture of pickles. *Betel pepper*, the leaf of which is so extensively used in India and its islands as a masticatory, is the produce of *Piper Betel* (Linn.), or *Chavica Betel* of Miquel. It is not imported into Europe. *Cubeb pepper* is the dried berries of *Cubeba officinalis*. They are rather smaller and less wrinkled than those of black pepper, and are of a dark brown colour. Cubeb pepper is extensively used in medicine, and has been in high esteem from a very early period. It was employed by the Moors; and in England, during the reign of Edward I., the London merchants held the right to levy a toll of one farthing per pound upon all cubebs carried over London Bridge,—an indication that even then this medicinal pepper constituted an important article of commerce. In 1856 the imports to the United Kingdom were 25¼ tons, worth from L.5 to L.6 per cwt. *Cayenne pepper* is a compound condiment, the principal ingredient in which is the epidermis and pulp of the common capsicum (*Capsicum annuum*, Linn., Nat. Ord. *Solanaceæ*), a plant very extensively cultivated in most tropical countries, but said to have been procured originally from South America. The best Cayenne pepper is made in the West Indies. The berries, which are often larger than an egg, although other varieties are scarcely larger than a clove, are opened, and the seeds are taken out; the scarlet epidermis and pulp are then well beaten up with flour and salt into a paste, which is afterwards baked until quite hard, and then ground into a coarse powder, which is put into well-corked bottles for use. Other methods are used, but this is the mode of preparing the much-prized West India Cayenne pepper. The *Neilgherry pepper*, so highly esteemed by East Indian epicures, is prepared in a similar manner from the berries of a yellow variety of the same species, which is cultivated for the purpose on the Neilgherry Hills. It is flavoured with cumin and other aromatic seeds. The two last-mentioned condiments, though so essentially different from the true peppers, pay the same duty (6d. per lb. and 5 per cent.), and are included in the same returns as the others, with the exception of cubeb pepper, which, as a drug, is duty free. The quantity imported in 1856 was 4826 tons, worth L.224,746. Of this enormous quantity, 2238 tons were re-exported. It was

principally imported from British India direct; but some was also sent from the Dutch possessions in Java, and other places.

Pepper is occasionally adulterated with farinaceous matter, such as starch or powdered rice; and bone-dust, known to the trade as "ivory-dust," is sometimes used to adulterate white pepper. An adulterate for pepper, under the name of "P.D." (*i.e.*, pepper-dust), is manufactured from rape or linseed cake, mustard dross, and Cayenne pepper. (See "Blue-book" on *Adulteration of Food*, &c., 1856.)

PEPYS, Samuel, author of the well-known *Diary* which bears his name, was descended from the Pepyses of Cambridgeshire, and was born on the 23d of February 1632. His family had some pretensions to gentility, but his father exercised the humble trade of a tailor in the city of London. Passing from St Paul's school in 1650, young Pepys became a sizar in Trinity College, Cambridge, but removed shortly after to Magdalen College. The only record we possess of his university career is contained in a memorandum of discipline entered in the Register-book of his college, where we read how Samuel and one Hind "were solemnly admonished for having been scandalously overserved with drink ye night before." The next notice we obtain of his progress is in October 1655, when we discover that he has married a girl of fifteen fresh from a convent. As this young lady had more of pedigree than portion, Pepys was glad to accept of an asylum in the family of his cousin, Sir Edward Montagu, afterwards Earl of Sandwich, a gentleman who proved his fast friend through life. He attended his patron on his expedition to the Sound in March 1658, and on his return received a clerkship connected with the Exchequer. It was about this time that Pepys began his interesting *Diary*, which he continued without interruption from 1st January 1659–60 for upwards of nine years, when defective vision compelled him to desist. His new appointment of Clerk of the Acts of the navy, in June 1660, brought his valuable business talents into notice, and he soon gained the confidence and esteem of the Duke of York, then Lord High Admiral. The intelligence and energy which Pepys brought to bear upon the reformation of the affairs of the navy, were attended with the best results during the critical times consequent upon the Dutch war. The plague visited the metropolis in 1665, but Pepys courageously stood by his post when every branch of the service was completely deserted. The fire of London followed; and no man did more to arrest the progress of that calamity than the Clerk of the Acts. On the resignation of the Duke of York in 1673, upon the passing of the Test Act, Pepys was appointed by his Majesty Charles II. to the important post of Secretary to the Admiralty. His close connection with the late Lord High Admiral was like to involve the new secretary in a share of the odium to which that nobleman was exposed. Pepys and Sir Anthony Deane were committed to the Tower on the 22d of May 1679, on the charge of being secret enemies of the Protestant cause, and of maintaining a clandestine correspondence with the French government respecting the condition of the English navy. They had to find security in L.30,000; but the foul depositions were shortly afterwards withdrawn, and the prisoners discharged. Charles having taken a fancy for again changing the constitution of the Admiralty, Pepys lost his post for a time as secretary. Meanwhile he accompanied Lord Dartmouth to Tangier, and employed his shorthand in preserving some records of the expedition. These notes were deciphered and published in 1841 from the MS. in the Bodleian Library. On his return, Pepys was re-installed in his secretaryship; a post for which no man in England was better qualified, and which he was allowed to occupy till the reign of James II. came to an end. He enjoyed much of the confidence of the latter monarch. We are told that on the arrival of the news that the Prince of Orange had landed, James was sitting to Kneller for his picture, which was intended as a present to the secretary of the Admiralty. That his "good friend might not be disappointed," the king commanded the painter to proceed, and complete the picture. Much of the credit frequently accorded to James II. for "renovating the navy" is unquestionably due entirely to Pepys. For the part borne by him in the naval history of the period the reader will find ample details in his *Memoirs relating to the State of the Royal Navy of England, determined December* 1688, 8vo, London, 1690. The studious retirement which Pepys sought, on being deprived of his official employments at the succession of William and Mary, was devoted to the arrangement of his extensive materials for a general history of the *Navalia* of England. Death came, however, to cut the work short on the 26th of May 1703.

Judging from the great variety, both of his duties and amusements, Pepys must have been a man of singular versatility. Despite his burdensome duties in connection with the affairs of the navy, which must have absorbed no ordinary degree of strength and courage, there seems to have been positively no end to the play-going and amusement in which the author of the *Diary* indulged. He sat for many years, besides, in the House of Commons; he was a connoisseur in the fine arts; he practised music; he patronized letters; and, to crown all, he was president of the Royal Society for two successive years. Among the invaluable MSS. bequeathed by him to Magdalen College, Cambridge, is to be found a remarkable collection of English ballads, from which were taken a large portion of Percy's *Reliques*. A small anonymous book in the Pepysian Library is likewise ascribed to him by Watt (*Bibliotheca Britannica*), entitled *A Relation of the Troubles in the Court of Portugal in* 1667 *and* 1668, by S. P., Esq., 12mo, London, 1667. But the work on which the reputation of Pepys chiefly rests is the *Diary* already alluded to, which was exhumed from its stenographic obscurity by the skill of John Smith (then a young student at Cambridge, afterwards rector of Baldock, Herts), and published, with a selection from the author's private correspondence, by Lord Braybrooke, in 2 vols. 4to, London, 1825. A third edition appeared, by his lordship, in 1848, containing very extensive and interesting additions formerly left out, with a Life and Notes, extending in all to 5 vols. 8vo. There is perhaps no book, either in our own or any other language, which presents such lively and truthful delineations of the society and manners of a former age. The *Diary* of Pepys is invaluable as a history of the court and times of Charles II.; yet, from its endless diversity of quaint gossip and amusing detail, drawn from domestic life and personal experience, it is, at the same time, unquestionably the most interesting book of its kind in existence.

PERA, a suburb of Constantinople, N. of the "Golden Horn," and connected with the city proper by a bridge of boats. It occupies the summit of the hill on which Galata is built, and is separated from that suburb by a wall, and entered by gates, which are closed during the night. Owing to its lofty and salubrious position, Pera is chiefly inhabited by Europeans; and it has not at all a Turkish appearance, but rather resembles a small Italian town. Most of the foreign ambassadors and the dragomans reside here. A great number of houses, including the palace of the British ambassador, were burned down in 1831; but these have been since rebuilt in a better style than formerly. Since then it has several times suffered from fire. There are a Greek and several Roman Catholic churches, a Mohammedan college, and a monastery of dervishes.

PERAK, an independent state on the west coast of the Malay Peninsula, lies between Keddah on the N., and Sangalore on the S. It is watered by a river of the same

name; and is partly mountainous, and partly consists of rich alluvial plains. There are valuable tin mines, producing upwards of 3600 cwt. of tin annually. Gold is also obtained by washing in many of the streams. The country was at one time subject to Siam, but is now governed by a sultan of its own. The population is estimated at 35,000 Malays, exclusive of the aboriginal tribes in the interior.

PERAMBULATOR, in surveying, an instrument for measuring distances, called also an *odometer*, and a *surveying-wheel*.

PERCEPTION. See METAPHYSICS.

PERCEVAL, SPENCER, an English statesman, the second son of John, Lord Egmont, was born in 1762, and received his education at Harrow, and at Trinity College, Cambridge. Becoming a member of Lincoln's Inn, and pursuing the study of law with a close and unwearied attention which stooped to the most minute details, he soon laid the foundations of future eminence. Accordingly, he had not been long in Parliament as member for the borough of Northampton, when he entered upon a career of promotion. Under the Addington administration, the office of solicitor-general was conferred upon him in 1801, and the office of attorney-general in 1802. On the overthrow of the Grenville ministry in 1807, he was appointed chancellor of the exchequer; and on the retirement of the Duke of Portland from the premiership in 1809, he succeeded to the post of prime minister of Great Britain. His administration was marked by strong opposition to the tolerant views which had ruined his predecessors; and he is one of the few English statesmen who have rendered themselves notorious from the rancour of their religious intolerance. He seems to have been a man of a cold, ungenial nature. Perceval was still at the head of affairs when he was shot by an assassin named Bellingham in the lobby of the House of Commons on the evening of the 11th May 1812.

PERCH (Lat. *pertica*, a long staff or pole frequently used in measuring land) is used, like the word *pole*, as a denomination both of lineal and of superficial measure. As a measure of length, it is equal to $5\frac{1}{2}$ yards, or $16\frac{1}{2}$ feet; in square measure, the perch is the $\frac{1}{40}$th part of a rood, or equal to $30\frac{1}{4}$ square yards. (See WEIGHTS AND MEASURES.)

PERCIVAL, THOMAS, an eminent physician and moralist, was born at Warrington in Lancashire in 1740. His characteristic enthusiasm began to appear at an early age. After studying with great ardour at the newly-instituted academy of his native place, he devoted himself to the medical profession. He began his studies at Edinburgh in 1761, continued them at London in 1764, and finished them by graduating at Leyden in 1765. But it was not until 1767, when Percival commenced to practise as a physician in Manchester, that his enthusiasm obtained its full scope. Fond of his profession, addicted to scientific investigations and discussions, earnest, and religious, he now entered upon a career of wide and varied activity. He became a frequent contributor to the *Philosophical Transactions* of London; and he became the chief instrument in establishing the Literary and Philosophical Society of Manchester. His numerous papers on medical subjects were devoted to the cause of public health; and his *Moral Dissertations*, *Instructions to Children*, and *Medical Ethics* were consecrated to the interests of public morality. His professional duties were also discharged with the most conscientious assiduity till his death in August 1804. The entire works of Dr Percival, accompanied with a Life, were published by his son, in 4 vols. 8vo, London, 1807.

PERCY, THOMAS, Bishop of Dromore, editor of the well-known *Reliques of Ancient English Poetry*, was born of humble parents at Bridgenorth in Shropshire on the 13th of April 1728. He had his elementary education at the free school of his native town, and entered Christ Church, Oxford, as an exhibitioner in July 1746. On being presented to the vicarage of Easton-Mauduit in Northamptonshire, and to the rectory of Wilby in 1756, he commenced a career of faithful pastoral labour, relieved as often as leisure would permit by the cultivation of literature. In 1761 he came before the public with a translation from the Portugese of a Chinese story in four volumes, entitled *Hau Kiou Choaan*. This performance was followed up by *Chinese Proverbs*, and a new version of *Solomon's Song*. In 1763 he published a translation into Latin prose of five pieces of Runic poetry, and the year following a *Key to the New Testament*. Percy had by this time formed an intimacy with the most eminent men of letters then in England. Samuel Johnson visited him at his vicarage in 1764, and spent three very happy months in the society of the learned ecclesiastic, then in eager pursuit of old heroic ballads and songs. It does not appear, however, that Johnson showed a very lively sympathy with those reliques of ancient minstrelsy. Men of letters and professed antiquarians gave him their aid or encouragement; and "the last male descendant of the ancient house of Percy" gave "Otterbourne" and "Chevy Chase," and the rest of the famous *Reliques*, to the world in 1765. The greater part of this collection was taken from an ancient folio manuscript in the editor's possession, containing nearly 200 compositions of all times and dates, from the ages prior to Chaucer to the conclusion of the reign of Charles I. The Pepysian Library at Magdalen College, Cambridge, likewise furnished some valuable pieces. (See PEPYS.) The reception given to these immortal ballads was at first by no means enthusiastic. Percy received 100 guineas for the first edition; and what was more substantial, was made chaplain in ordinary to the king in 1769, dean of Carlisle in 1778, and bishop of Dromore in 1782. In this Irish retreat, where a century before Jeremy Taylor had nursed his fine genius to a ripe maturity, Percy continued to prosecute his literary studies, to administer comfort to the poor, and spiritual consolation to all. In addition to the works of this elegant scholar already specified, he in 1770 printed the *Northumberland Household Book*, and a poem connected with the history of the family of Percy, written in imitation of the old ballad, and entitled *The Hermit of Warkworth*. It was during the same year that his translation of Mallet's *Northern Antiquities* was given to the public. Interesting remains of Bishop Percy are still to be found in *The Percy Correspondence*, published by John Bowyer Nichols. His assiduous application to study, and especially to old manuscripts, cost Percy his eyesight. He had become quite blind before his death, which took place on the 30th of September 1811, in the 83d year of his age.

PERDICCAS, the name of three kings of Macedonia. The first is supposed by Herodotus to have been the founder of the monarchy; the second was the son and successor of Alexander I.; and the third was the son of Amyntas II., and the successor of his brother, Alexander II. (See MACEDONIA.)

PERDICCAS, one of the most distinguished of the generals of Alexander the Great. (See MACEDONIA.)

PEREIRA, JONATHAN, a distinguished pharmacologist, was born on the 22d of May 1804 in the parish of Shoreditch, London. Passing from a classical academy, Queen Street, Finsbury, where he had received his preliminary education, he was at the age of fifteen articled to a navy surgeon in the City Road. In 1821 his apprenticeship was brought to a termination, and he entered as a student at the Aldersgate General Dispensary, and at St Bartholomew's Hospital. At these institutions he had an opportunity of devoting himself with ardour to those studies which he had prosecuted with so much zeal in private during the years of his apprenticeship. In 1823 Pereira obtained the appointment of apothecary at the Aldersgate Street Dispensary, and began to give lessons to

private pupils preparatory to their medical examination. His success in this undertaking already pointed him out as a person destined to rise to distinguished eminence as a public instructor. It was during this period that he commenced his career as an author by publishing for the use of students a translation of the London *Pharmacopœia*, *Selecta e Præscriptis*, which has gone through many editions; *A Manual for the Use of Students;* and *A General Table of Atomic Numbers, with an Introduction to the Atomic Theory.* Pereira had just completed his twenty-first year when, in 1825, he was made lecturer on chemistry at the Aldersgate Street Dispensary; and three years afterwards he commenced a course of lectures on his favourite subject of Materia Medica. As a scientific teacher he soon attained an extensive popularity, and his class became the largest of the kind in London. He resigned his office of apothecary in 1832, married, and established himself in general practice in Aldersgate Street. In the winter of the same year he was elected professor of Materia Medica in the New Medical School in Aldersgate Street, and was made lecturer on chemistry at the London Hospital. To pave the way for his great work, *The Elements of Materia Medica*, on which he was then busily engaged, Pereira published his lectures on that subject in the *Medical Gazette* for 1835–6–7, which contributed greatly to raise his reputation both at home and abroad. His *Elements* appeared in 1839–40; and about the same time he was appointed examiner in Materia Medica at the London university. He was chosen assistant physician to the London Hospital in 1841, having previously become a licentiate by examination of the College of Physicians, and having obtained the degree of M.D. from the university of Erlangen. On the opening of the School of Pharmacy in 1842, Dr Pereira delivered two lectures at that institution "On the Elementary Composition of Food," which he subsequently amplified into *A Treatise on Food and Diet.* In 1843 he published his *Lectures on Polarized Light;* and during the same year became professor of Materia Medica to the Pharmaceutical Society, a position which he continued to occupy till 1851. The greater number of Pereira's valuable contributions to the *Pharmaceutical Journal* were made at this period. In 1845 he was elected a fellow of the Royal College of Physicians, and shortly afterwards was appointed curator of the museum of that institution. His death, which took place on the 20th of January 1853, in the forty-ninth year of his age, was caused by the rupture of a blood-vessel about the heart, induced by the effects of a severe fall. As an authority in Materia Medica, Dr Pereira had few equals in Europe.

PEREJASLAV, or PEREJASLAVL, a town of European Russia, government of Poltava, at the confluence of the Alta and the Frubesh, 176 miles W.N.W. of Poltava. It is an ancient town, and is defended by an earthen wall and a dilapidated fortress. Brandy is made here, and some trade is carried on in corn and cattle. Pop. (1852) 10,848.

PEREKOP, a town of European Russia, in the government of Taurida, stands in an unhealthy position on the isthmus of the same name, joining the Crimea to the mainland, 88 miles N.N.W. of Simferopol. It is defended by irregular wooden fortifications and by a strong castle. There are here a Greek church and a mosque; and large fairs are held, frequented chiefly by the Nogai Tartars. The principal trade carried on is in salt, which is obtained in the neighbouring steppes. Pop. (1849) 4116. The isthmus of Perekop is about 20 miles long, and 4 miles broad at the narrowest part. It separates the Gulf of Sivach on the E. from that of Perekop on the W., and where narrowest is crossed by a rampart and ditch.

PEREZ, ANTONIO, the natural son of Gonzalo Perez, for a long time secretary of state to Charles V. and Philip II., was born in 1541 at Monreal de Ariza in Aragon, and legitimated by imperial diploma in 1542. In his boyhood he accompanied his father, who attended the court through Europe, and received the elements of education at Louvain and Venice, which he finished in Madrid. Trained by his father to succeed him, he became, at the death of the latter, the principal of the two secretaries of state, and had the charge of the *despacho universal.* The royal council was divided into two hostile parties, headed respectively by Ruy Gomez, Prince of Eboli, and by the Duke of Alva: Perez adhered to the former, which had been all-powerful since the failure of Alva in the Netherlands, and continued so after the death of Ruy Gomez in 1573, till his own disgrace in 1579. Adroit, devoted, and unscrupulous,—an able writer, and assiduous in business,—he had by degrees assumed the highest place in the king's confidence, and was the depositary of the dangerous secrets of that suspicious tyrant. In this unenviable eminence he behaved himself imprudently, creating enemies among the nobles by ostentatious contempt, as well as by the wealth which he extorted from petitioners, and acquired (as Spanish ministers have generally done) by the sale of offices and titles. His own account of the disgrace which determined the whole of his subsequent history is, that, being authorized by the king to ensnare Escovedo, then supposed to be engaged in a plot for securing the Spanish crown for his master, Don Juan, the king's brother, Perez, after several unsuccessful attempts at poisoning Escovedo, caused him to be stabbed in the street on the 31st of March 1578. Perez's real motive, however, for the murder, was to get rid of a dangerous enemy; for Escovedo was acquainted with an intrigue of Perez with the Princess Eboli, the king's mistress, and the murderer feared his conduct might reach the ears of Philip. That this was the real motive of Perez was long questioned by historians. So high an authority as Ranke discredited it; but it has been placed beyond doubt by the researches of Mignet, which appeared first in the *Journal des Savans*, and were afterwards published separately, and appeared in an English translation in 1846. Rumour at once fastening on the real motive and culprit, the relatives of Escovedo demanded justice; and having discovered the truth, Philip had the Princess Eboli and Perez simultaneously arrested. Perez was sentenced in 1585 to ten years' banishment (including two years' close imprisonment), and heavy restitution and fine. He was shut up in the fortress of Turreguano, where he had the society of his wife, Juana Coëllo, whose whole life gave proof of a remarkable fidelity and self-devotion. To compel him to give up the documents that implicated Philip, he was put to the torture (February 1590), a stretch of power which had no other effect than to procure for him the sympathy of the nobles, whose privileges were violated in his person. On the 20th of July of the same year, assisted by his faithful friend Gil de Mesa, he escaped to Saragossa in Aragon, and placed himself under the protection of the *fueros* or independent jurisdiction of that kingdom. The events that ensue belong to Spanish history; for it was the protection Perez received from the fueros, and the spirited resistance to the arbitrary invasion of them in his case, that gave Philip, who had been long secretly undermining them, the pretext for their abolition by force of arms.

Acquitted by the court of Saragossa, the attempt was made by the monarch's instruments to transfer Perez forcibly to the prison of the Inquisition, a charge of heresy being got up against him out of the passionate blasphemies he was too apt to utter when enraged by his misfortunes. A popular insurrection set him at liberty, in which the Marquis of Almenara, viceroy in Aragon, lost his life.

In the reaction produced by this unlucky catastrophe, the attempt was repeated under more legal forms; but a second insurrection, contrived by the friends of Perez, frustrated it, and he was able to escape to France. He

was received with kindness at Pau by the Princess Catherine, who brought him to her brother Henri IV., at Tours, in the spring of 1593. Henri sent him on a secret mission to the coast of England, where he warmly and ably seconded the active counsels of the Earl of Essex, which well accorded with his own animosity against his former master. Through Essex he became intimate with Francis and Antony Baca, and received a pension of L.130. While in England he published his *Relaciones* in 1594, under the name of Raphael Pelegrino. In January 1595 he was recalled by Henri IV., who had declared war against Philip II. He received as residence a house that had belonged to the Duc de Mercœur and a guard to protect him against assassination. His position, however, was precarious and irksome. An unsuccessful mission to England in 1595, aggravated his discontent, and the part he played in the treaty with Spain in 1597 had not the effect of strengthening his interest with the French king. The succession of Philip III. in 1598 raised his hopes again; but it was not till April of the following year that his wife and children were liberated. All the efforts he made to get himself recalled were, however, vain; a mission which he undertook to England in the interest of Spain in 1604, and on the strength of which he resigned his pension, ignominiously failed: he was obliged to leave England as soon as he had arrived, and returned to France to spend his last days in want, solitude, and despair. He died 3d November 1611, and was buried in the Célestins.

Perez has an eminent place in Spanish literature. Besides the *Relaciones* above mentioned, the *Memorial* and *Comentarios* relating to that work, which is not very trustworthy, he published *Cartas Familiares*. Many of these letters are in Latin; those, namely, to Essex and his other English and French friends. They have the same essential qualities as those in his own language to his family and friends in Spain. His faults are those of his age; and some of them were adopted from the fashionable euphuism of England. He has conceits, false and strained analogies, in abundance; the whole vocabulary of mythology, and the fabulous natural history in vogue, are at his command; of Tacitus he imitated the compression and the obscurity; he affected the sententious smartness of Seneca: these were his favourite authors. On the other hand, he has passages of a noble and touching pathos, happy similitudes well hit off, and much of the bitter wisdom of disappointment. He had seen the great very closely, had been the secretary and agent of a dark and tortuous tyrant, knew well and cleverly delineates the Machiavelism of the age. Many of his sharp sentences have become proverbial; many deserve to become so. A Life of Philip II. by him is in existence, but has not been published.

PERFUMERY is the art of preparing certain substances for the gratification of the sense of smell. But according to a modern professor of the art (Madame Celnart, *Manuel du Parfumeur*, Paris, 1845), perfumery has a much more extensive range, including the preparation of *volatile oils*, *pommades*, *absorbent powders* for increasing, and *depilatories* for diminishing the growth of hair; *creams* and *cosmetics* for the skin; almond and other *pastes; dentifrices*, and *mouth-washes; essences* and *scented waters;* dry perfumes, such as *pastilles*, *cassolettes*, and *printanniers*, or little perforated ivory boxes containing a dry scented paste, to be worn in the pocket; *sachet powders* for insertion in silken bags or ornamental envelopes; *aromatic vinegars*, and *toilet soaps*, *hair powders*, and *bandolines*, hard and liquid, for dressing the hair. All these names indicate as many different classes of perfumes, and each class sometimes contains an almost endless variety, as in the various scents for the handkerchief, oils for the hair, &c.

The use of perfumes has been common among most nations from the earliest times. The monuments of ancient Egypt represent the censer exhaling its grateful odour before the presiding deity; and the surfaces of tombs often represent the preparation of spices and perfumes for the embalming of the dead. The unrolling of the mummy in our museums has placed in our hands the costly perfumes actually used by the ancient Egyptians. Frequent reference is made in Holy Scripture to perfumes. In Exod. xxx., Moses is directed to take pure myrrh, sweet cinnamon, sweet calamus, cassia, and oil of olive, which he is to compound, "after the art of the apothecary," for a holy anointing oil. He is also directed to take sweet spices, stacte, onycha, galbanum, and pure frankincense, to make a perfume to be placed "before the testimony in the tabernacle of the congregation." Several perfumes are also mentioned in the Canticles,—iv. 14; Ps. xlv. 8; Prov. vii. 17; Jer. vi. 20; and other passages, of which the most familiar in the New Testament is in Mark xiv. 3, where a woman "having an alabaster box of ointment of spikenard, very precious, brake the box, and poured it on his head." The ancient Greeks and Romans made free use of perfumes, which they carried in costly and elegant boxes to the bath, after the use of which they anointed and scented themselves. Perfumes are still largely used in the East, where it is the custom to sprinkle guests with rose-water, and to perfume them with aloes-wood at the close of a visit, as a mark of hospitality and friendship. The use of perfumes in Great Britain, at least among the male sex, has greatly declined since the free use of soap has become general. The man who is most fastidious about his dress now hesitates to employ perfumes freely, lest he should become obnoxious to the sarcasm of the poet Cowper:—

"The sight's enough; no need to smell a beau."

Still, however, the trade in perfumes is enormous, a considerable portion of the industry of the south of France being employed in their preparation. Cannes is celebrated for perfumes produced from the rose, tuberose, cassia, jasmine, and orange *neroli*. At Nismes, thyme, rosemary, aspic, and lavender are manufactured. Nice is famous for the products of the violet and *reseda;* Sicily for those of the lemon, the bergamot, and the orange; England excels in the preparation of lavender and peppermint; Mitcham in Surrey, and Hitchin in Hertfordshire, being celebrated for their essential oils.

Perfumes are chiefly of vegetable origin, although there are a few of animal, such as musk and civet, and of chemical, such as the salts of ammonia. Various parts of a plant may contribute odour: in some cases it is the root, as in the iris; in others, the stem or wood, as in cedar; or it may be the leaves, as in mint; or the flower, as in the rose and the violet; or the seed, as in the Tonquin bean; or the bark, as in cinnamon. Some plants give more than one odour: thus the orange tree yields three,—namely, *petit grain*, from the leaves; *neroli*, from the flowers; and the essential oil of orange, called *Portugal*, from the rind of the fruit.

Vegetable odours are due to volatile oils contained in certain small vessels or sacs, or generated from time to time during the life of the plant, as when it is in blossom. Some odours exude by incision, as in the case of certain odoriferous gums, such as benzoin; or balsams, which are mixtures of an odorous oil and an inodorous gum. Some balsams are prepared, in the country which produces the plants, by boiling the plant in water, straining, and evaporating to the consistence of treacle; as in the case of balsam of Peru, which is prepared from the *Myroxylon peruiferum*. Such balsams are used for mixing with soap, and in some cases medicinally.

Perfumes are for the most part prepared by one of four operations, namely,—(1.) *Expression;* (2.) *Distillation;* (3.) *Maceration;* (4.) *Absorption* or *enfleurage*. By the first operation essential oils may be obtained, such as the oil of orange, of lemon, or of citron peel. The peel is packed

in a cloth bag, and subjected to pressure in a powerful iron press. The oil which exudes is contaminated with the watery extract, but the different fluids separate on being left to repose in appropriate vessels, and the oil can be removed by means of a pipette. In the second process, the herbs are put into a still, together with a quantity of water, which being raised to the boiling point, the volatile otto comes over with the steam. Spirit is sometimes used in the still, but it is better to draw the oil first with water, and then to dissolve the oil in spirit. The products of the distillation are put into a funnel, and they separate by standing. The stills are heated by means of steam, by which the risk of burning and imparting an empyreumatic flavour to the products is avoided. Some idea of the extensive nature of the operation of distilling may be formed from the fact, that at Mitcham a ton of herbs is distilled at one operation. With the exception of the essential oils of lavender and peppermint, the south of France is the great seat of the manufacture of essential oils,—such as those of the rose, neroli, lemon-thyme, and rosemary. In preparing the essence of roses, the water and the roses are put into the still until one-half of the water has been distilled off, and when a considerable quantity of water of the first distillation has been obtained, it is used as water upon fresh rose-leaves; and this plan is repeated five times. In distilling orange-flowers to obtain the essence of neroli, the same process is adopted; but orange-flower water is obtained at the first distillation.

By means of maceration, or, as the perfumer sometimes calls it, *infusion*, a variety of pommades, scented oils, and scented spirits are prepared. The vessel containing the liquid, such as the fat, oil, or spirit, together with the essential oil, or the parts of the plant which afford the scent, is heated by means of a water-bath or *bain-marie*. The fat for pommades should be first pounded in a marble mortar until the membranes are completely torn: it should then be heated in a water-bath, skimmed, and filtered through canvas. Mr Piesse, in his work on *Perfumery* (2d edit. 1856), speaks of the *oil of behn*, from Jamaica, as being a perfectly inodorous fat oil, well adapted for extracting the odours of flowers by maceration. In preparing rose, orange-flower, and cassia pommades, a quantity of lard and beef suet are melted in a pan called a *bugadier;* the rose-leaves are stirred in, and left for twenty-four hours, when the mass is again melted, strained, and fresh flowers are added; and so on for ten or fifteen times. In some cases the pommade is made into rectangular bricks, and pressed to separate the solid matter from the soft pommade: the bricks are then put into a perforated barrel, and pressed until the pommade exudes and flows into a copper vessel placed under the trough of the press. In preparing scented spirits, the essential oil and spirits of wine are digested in a water-bath, and frequently agitated during three days, when the spirit is drawn off into a second digester, and after three days to a third digester, with similar treatment. The celebrated *eau de Cologne* is prepared by distillation and infusion, the latter process being preferred. The successful preparation of this perfume is regarded as the perfection of the art. The various essential oils of which it is composed ought to be combined so harmoniously that no one of them shall be perceptible, not only at the first impression, but during the evaporation of the scent; a remark which should apply to other perfumes. When the ingredients differ but little among each other in odour and volatility, the desired result may be more easily attained. The constituents of *eau de Cologne* are said to be the essential oils of the lemon, the citron, and the orange, prepared from the fruit in different stages of maturity, and they approach so closely to each other as to produce only a single aromatic impression. Minute proportions of other oils are added, such as otto of roses, oil of cloves, or oil of cinnamon; but the *eau de Cologne* is regarded as of inferior quality if a residuary odour of either of these substances remains after volatilization. Perfumes for the handkerchief are known to the perfumer as simple or compound,—the former being called *extracts, esprits*, or *essences;* and the latter, *bouquets* or *nosegays*.

By the process of absorption or *enfleurage* pommades and scented oils are extensively prepared, for which purpose a square four-sided frame or *chassis*, two or three inches deep, with a pane of glass resting on its inside ledges, is used. On this pane of glass a simple pommade of hog's lard and suet is spread, and into this sweet-scented flowers are stuck every day for two or three months, until the pommade is sufficiently rich in perfume. Several thousand frames are operated on in this way, and they are arranged in piles over each other. Pommades of jasmine, tuberose, violet, &c., are prepared in this way. The oils of the same flowers are similarly prepared. Cotton cloth, stretched in an iron frame, is imbued with the best olive-oil, and completely covered with a thin layer of flowers. Upon this is placed another frame treated in the same manner, and a pile is made in this way; and when the oil is saturated with the odour of the flowers the pile is carefully pressed, and the scented oil flows out. Rose, orange-flower, and cassia oils, however, are made by infusion.

For the proportions in which the various ingredients are used, particulars of manipulation, apparatus, &c., we must refer to books appropriated to the subject, such as that of Mr Piesse; but we cannot close this short article without remarking how so apparently trivial a subject as perfumes rises in dignity as soon as it touches on chemical science. So long as the perfumer confined himself to empirical processes and shallow secrets, science did not disturb his operations; but when it was asserted, at the time of the Great Exhibition of 1851, that certain essences in extensive use had for some time previously been prepared by artificial means, the chemist took a lively interest in the perfumer. It appeared that a scent called *winter-green oil*, obtained from an ericaceous plant, the *Gaultheria procumbens*, had been imported in considerable quantities from New Jersey in America. Now, it was found that this oil was a true compound ether, consisting of salicylic acid and pyroxylic spirit, and capable of being formed by a combination of these substances, so as to possess all the characters of the natural product. This observation led to the discovery, that among the numerous ethers prepared by the chemist, some, on being properly diluted, presented the odour of certain fruits so decidedly that it appeared all but certain that the fruits themselves were indebted to these ethers for their odours. (See CHEMISTRY, vol. vi.; also OILS, *Essential*.) (C. T.)

PERGAMUS, or PERGAMUM, an ancient city of Mysia in Asia Minor, was situated on the north bank of the Caïcus. The facts regarding its origin are not authenticated. It is said to have been founded by a colony of Arcadians, and to have derived its name from Pergamus, a son of Pyrrhus. At any rate, in the time of Xenophon it was a strong town perched on the top of a conical hill, and numbering many Greeks among its inhabitants. In course of time its population began to increase; houses began to be grouped round the foot of the Acropolis; and the city continued to grow in importance until about 283 B.C., when it became the seat of a kingdom. The first sovereign was one Philetærus, an eunuch, and a Paphlagonian by birth. This man being in the service of Lysimachus, King of Macedonia and Thrace, was appointed by him keeper of the treasures lodged in Pergamus. Whilst he held this employment, having fallen under the displeasure of Arsinoë, wife of Lysimachus, she found means to excite a quarrel between him and his master, upon which Philetærus seized on the town, together with the treasures entrusted to his care. At first he offered his service, together with his

treasure, to Seleucus, the King of Syria; but both Seleucus and Lysimachus dying soon afterwards, he contrived to keep possession of the town and treasure until his death, which happened in 263 B.C., twenty years after his revolt from Lysimachus.

The city of Pergamus was left an independent state to Eumenes I., the nephew of Philetærus. This ruler laying hold of the opportunity offered by the dissensions amongst the Seleucidæ, possessed himself of many strongholds in the province of Asia; and having hired a body of Galatians, defeated Antiochus Soter near Sardis. By this victory he obtained possession of the greater part of Asia. But he did not long enjoy his acquisitions, for he died next year of immoderate drinking.

Eumenes was succeeded, in 241 B.C., by Attalus I., who was also a nephew of Philetærus, and who was the first to assume the title of King of Pergamus. He defeated the Gauls, who seemed desirous of settling in his territory; and, according to Livy, he was the first of the Asiatic princes who refused to pay a contribution to these barbarians. Taking advantage of the wars in which Seleucus Ceranus was engaged, he invaded the territories of that monarch, and conquered all the provinces on the Anatolian side of the Taurus. Seleucus, however, with the aid of Achæus, soon deprived him of all his newly-acquired territories, and even besieged him in his capital. Upon this, Attalus, inviting to his assistance the Gauls who had settled in Thrace, not only obliged the enemy to raise the siege of Pergamus, but quickly recovered all the provinces he had lost. After this he invaded Ionia and the neighbouring provinces, where several cities voluntarily submitted to his sway. Thence he advanced to Apia, and, encamping on the banks of the River Megithus, received homage from the neighbouring nations. But here the Gauls, being frightened by an eclipse of the moon, refused to proceed farther; a circumstance which obliged the King of Pergamus to return to the Hellespont. Attalus now entering into an alliance with the Romans, joined them in their war against Philip, King of Macedonia. In this war, in command of the Rhodian fleet, he not only drove the Macedonians quite out of the Greek seas, but having landed his men, he invaded Macedonia, and obliged Philip to raise the siege of Athens. For these services the Athenians not only heaped on him all the favours they could bestow, but called one of their tribes by his name,—an honour which they had never before bestowed upon any foreigner. Attalus next attempted to organize a general confederacy of the Greeks against Philip. But whilst he was haranguing at Thebes, with a view to this object, and exhorting the Bœotians to enter into an alliance with the Romans against their common enemy, he fell in a fit of apoplexy. Having somewhat recovered, he was carried by sea to Pergamus, where he died soon after his arrival, in 197 B.C., in the seventy-second year of his age, and forty-third of his reign.

Attalus was succeeded by his eldest son Eumenes II. The latter was exceedingly attached to the Romans. He refused the daughter of Antiochus the Great in marriage, lest he should thus be led into a quarrel with that people. He also gave intimation to the Roman Senate of the transactions of Ariarathes, King of Cappadocia, who was making great preparations both by sea and land. Nor did his fidelity stop here. When he saw the war about to break out between Antiochus and the Romans, he sent his brother Attalus to Rome in order to give information of the proceedings of Antiochus. At the battle of Magnesia, too, he behaved with the greatest bravery, not only sustaining the first attack of the enemy's elephants, but driving them back again upon their own troops, and thus throwing the hostile ranks into confusion, and contributing materially to the complete victory of the Romans. Such assiduous services were well rewarded. On the conclusion of peace between Antiochus and the Romans, his dominion was extended over all the countries in Asia Minor west of Mount Taurus. Soon after this Eumenes engaged in an unsuccessful contest with Prusias, King of Bithynia, who made war upon him by the advice of Hannibal, the celebrated Carthaginian general. The Romans, however, interfered, and by their deputies not only put an end to the differences between the two kings, but prevailed on Prusias to betray Hannibal. Eumenes being thus freed from such a dangerous enemy, engaged in a new war with the kings of Cappadocia and Pontus, in which he proved victorious. His friendship for the Romans he now carried to such a degree of enthusiasm that he went in person to Rome to inform them of the machinations of Perseus, King of Macedonia. This journey, however, had almost proved fatal to him. On his return, as he was going to perform a sacrifice at Delphi, two assassins, sent by Perseus, rolled down two great stones upon him as he entered the straits of the mountains. He was so severely injured that a report of his death was spread over Asia; and on reaching home, he found that his brother Attalus had married his wife and assumed his crown. In spite of this flagrant attempt upon his life, however, Eumenes, on the outbreak of the war between the Romans and Macedonians, entered into negotiations with Perseus. He offered, if the latter would pay him a sum of money, to influence the Romans to grant him a safe and honourable peace. These negotiations were indeed broken off prematurely, but not before the Romans had begun to be suspicious, and to entertain no little jealousy of their old friend, and to heap favours upon his brother Attalus. Eumenes in alarm resolved to proceed in person to Rome, in order to justify himself. But the Senate having already condemned him in their own minds, resolved not to hear his vindication, and made an act that no king should be permitted to enter the gates of Rome. Accordingly, on landing at Brundusium, he was met by a quæstor, and ordered to quit Italy and go back to Pergamus without delay. On his return, the Gauls, encouraged by the cold reception which he had met with at Rome, invaded his territories, but were repulsed with great loss. This produced new complaints at Rome. Eumenes was accused of keeping up a secret correspondence with the King of Macedonia; and the senators having conceived the most implacable hatred against him, seemed absolutely bent on his destruction, when he died in 159 B.C., in the thirty-ninth year of his reign, leaving his kingdom and his wife to his brother Attalus.

Attalus II., in the commencement of his reign, found himself greatly distressed by Prusias, King of Bithynia, who not only overthrew him in a pitched battle, but advanced to the very walls of Pergamus, ravaging the country as he marched along, and at last reduced the royal city itself. The king, having saved himself by a timely flight, despatched ambassadors to Rome for assistance. Prusias was accordingly obliged to conclude a peace with his adversary, and to give indemnities. The last enterprise in which we find Attalus engaged was against Andriscus, the pretended son of Perseus, King of Macedonia, in which he assisted the Romans. After this he gave himself up to ease and luxury, committing state affairs entirely to his ministers; and thus continued till his death, which happened in the eighty-second year of his age, about 138 B.C.

Attalus II. was succeeded by Attalus III., the son of Eumenes II., and of Stratonice, the daughter of Ariarathes, King of Cappadocia. This prince is said to have been deprived of his senses through the violence of his grief for his mother's death; and, indeed, throughout his whole reign, he behaved more like a madman than a person of sane mind. On the death of this tyrant in 133 B.C., a will was found, by which he left the Roman people his heirs, upon which they seized on the kingdom, and reduced it to a province of their empire by the name of Asia Proper. Aris-

tonicus, however, a son of Eumenes by an Ephesian courtesan, reckoning himself the lawful heir to the crown, assembled a considerable army in order to maintain his pretensions. The news were speedily carried to Rome; and Licinius Crassus, the *pontifex maximus*, was sent into the East to vindicate the Roman claims. But he managed matters so ill that he was entirely defeated and taken prisoner by Aristonicus. Aristonicus did not long enjoy the fruits of his victory. He was soon surprised by Perpenna, the new consul, who obliged him to venture an engagement at a disadvantage, defeated him, and took him prisoner. The Pergamenians, notwithstanding the defeat and captivity of their leader, still held out with such obstinacy that Aquilius, the succeeding consul, was obliged to besiege and take by force almost every city in the kingdom. At last, however, the whole country being reduced, Aquilius triumphed, and the unhappy Aristonicus, being led in chains before his chariot, probably ended his miserable life in a dungeon.

The city of Pergamus retained its importance long after its subject territory had been thus reduced into the form of a Roman province. It still continued to be famous for its magnificent library, which had been founded by Eumenes II., and which contained, according to the ordinary reports, about 200,000 volumes. In the times of the New Testament it was the seat of one of the Seven Churches mentioned in the Apocalypse. In the age of Pliny it was by far the most celebrated city of Asia. Yet after passing into the Byzantine empire Pergamus gradually declined, and in course of time was transformed into the modern city of *Bergamah*. The ruins of a palace, of the temple of Æsculapius, of a theatre, and of other public buildings, are the only remnants of its ancient grandeur.

PERGOLESE, Giovanni Battista, one of the most celebrated musicians of the Neapolitan school. Among his biographers, Italian, French, German, and English, there are conflicting statements regarding his birthplace, the date of his birth, his surname, and the conservatory in which he was trained at Naples. By some of those he is surnamed Jesi; by others Pergolese, or Pergolesi; and is said to have been born in 1704 or 1707 at Pergola, a small town in the duchy of Urbino; and to have been educated in the conservatory of St Onofrio at Naples. According to the Marchese di Villarosa, who published a biography of Pergolese in 1831, and who had in his hands the official certificate of the musician's birth and baptism, Pergolese was the true surname, his birthplace Jesi, a small town near Ancona in the Papal States, and the date of his birth ten o'clock on the night of the 3d of January 1710. The Marchese di Villarosa asserts also that Pergolese was admitted in 1717 into the Neapolitan conservatory *dei Poveri di J. C.*, and not into the conservatory of St Onofrio, as has been so often stated. There Pergolese studied the violin under Domenico de Matteis, and musical composition under Gaetano Greco, and Durante, Greco's successor. It appears that Pergolese was patronized by the noble families Stigliano and Caracciolo. In his earlier productions he adhered to the severer style of Greco and Scarlatti, but afterwards adopted that of his fellow-student Vinci, who considered melodic freedom and dramatic expression to be the chief objects of music. Padre Martini remarked that some passages in the sacred music of Pergolese were more suitable for operatic compositions. His first great work was the oratorio of *San Guglielmo d'Aquitania*, in 1731. In 1731 and 1732 he composed his operas *Sallustia*, *La Serva Padrona*, *Lo Frate Innamorato*, *Il Prigionier Superbo*; and in 1734 the opera *Adriano in Siria*, and the intermezzo *Lirietta e Tracollo*. In the same year he was appointed chapel-master of the church of Our Lady at Loretto. In 1735 he produced the operas *I Flaminio* and *Olimpiade*. Suffering from pulmonary consumption, he retired to Pozzuoli, near Naples, and there composed his cantata *Orfeo*, a *Salve Regina*, and his famous *Stabat Mater*. He died there on 16th March 1736, and was buried in the cathedral church. Besides the above-mentioned works, Pergolese composed the following:—A three-act intermezzo, *La Contadina Astuta*; *Amor fa l' Uomo Cieco*; *Recimero*; *Il Maestro di Musica*; *Il Geloso Schernito*; two *Salve Regina*; a Mass for two choirs; a Miserere for four voices; a Confitebor for five voices; a Motett; a Mass for two voices; a Mass in D major; the score of an Oratorio on the Birth of Christ; a Laudate, with accompaniments; a Dixit, with accompaniments; four Cantatas for a voice, with harpsichord and violin; a Mass for ten voices; a Dixit for ten voices; a Confitebor in Canto-Fermo for four voices; six Cantatas, three of them with accompaniments for violin, viola, and bass, and three with harpsichord accompaniments; a violin Concerto; and thirty Trios for two violins, violoncello, and harpsichord. (G. F. G.)

PERIANDER, Tyrant of Corinth, succeeded his father Cypselus, about 625 B.C. He began to rule with a mild and beneficent sway, yet soon adopted a system of vigorous and salutary despotism. His first measure was to insure internal peace by shutting up the clubs, common tables, and other scenes of political discussion, by removing or strictly watching all the citizens of high birth and influence, and by prohibiting all that wasteful extravagance which might result in wanton misconduct or factious poverty. Then, in order to strengthen his power, he enrolled an army, equipped a fleet, and entered into leagues with both Grecian tyrants and barbarian kings. At the same time, it was his care to adorn his capital with magnificent architecture, and to grace his court with men of philosophy and letters. The last days of Periander were clouded by domestic misfortune. His wife Melissa died in consequence of a blow which he had given her in a fit of jealous rage. His younger son Lycophron was assassinated by the Corcyræans while residing among that people. The only member of his family that was left was his idiot son Cypselus. Overwhelmed by these calamities, the hoary tyrant died at the age of eighty, and after a reign of forty years. Periander is said by his biographer Diogenes Laertius to have left behind him a didactic poem, which consisted of moral and political precepts, and amounted to 2000 verses. It was this work, in all probability, which led some to rank him among the seven sages of Greece.

PERICARP. See Botany.

PERICLES, the greatest of Athenian statesmen, was born about the beginning of the fifth century B.C. The family influences amid which he was brought up were well calculated to foster political ambition. His extraction was noble; his patrimony was splendid; his relations held some of the high offices in the state; his maternal grandfather Cleisthenes was one of the expellers of the Pisistratidæ; and his father Xantippus was the conqueror of the Persians at the battle of Mycale. Yet these advantages of birth did not induce the youthful Pericles to enter prematurely into the arena of politics. Like an ancient athlete who subjected himself to a careful process of training before entering the lists at Olympia, he patiently prepared himself by the most thorough education. From Damon, a professed teacher of music, but in reality an inveterate politician, he learned the history and principles of the Athenian constitution. In the school of Zeno the Eleatic, he acquired the art of carrying an argument into the most intricate subtleties and sophistries, and of "making the worse appear the better reason." But it was especially under Anaxagoras, "the Intelligence," as he was called, that his mind attained its fullest development. In the genial atmosphere of that great man's philosophy his intellect expanded to receive the rays of truth, his heart warmed

with the largest sympathies, and his spirit stood forth clear, serene, and calm. The refining influence even passed into his outward frame. His features assumed a settled repose, and his bearing became instinct with an easy dignity.

Thoroughly prepared by this complete process of training, Pericles began his political career about 469 B.C. In no long time he was the recognised leader of the democratic party against the warlike Cimon, the chief of the aristocracy. His conduct in this position was very unlike that of other demagogues. Dwelling apart in self-satisfied seclusion like a king, and wrapped up in his own thoughts like a philosopher, he showed himself to be the master and not the slave of the mob. He would not injure his self-respect by making his power subservient to his avarice, and wringing from the horny grasp of labour its hard-earned gains. He would not demean his talents by studying the vicious tastes of the populace, and by haranguing them on every paltry occasion. To parade himself often in public, and to mingle in the society of his friends, was, he thought, to impair his magisterial dignity. Even to wince under popular abuse, or to return the enmity of political adversaries, was, according to him, to act unworthy of a man of superior capacity. He pursued a far different line of policy. The art of raising Athens to the height of prosperity was the only subject worthy of his study. The quiet of his own chamber was his only proper sphere. When he condescended to punish any public insolence, he waited silently until the reviler had exhausted himself, and then ordered his servant to light the rascal home, or to do him some other act of kindness. When it pleased him to court the favour of the people, he did it like a prince, giving them money out of the treasury to frequent the theatres, and paying them for their military service and for their attendance at the courts of justice. When he deigned to appear as a public orator, it was for some great cause worthy of his transcendent genius. Then his usual cloak of calm reserve was thrown aside, and he stood forth in all the native earnestness of his character. He mounted the *bema* with his oration thoroughly premeditated, and began to speak with a prayer to the gods that no inappropriate word might fall from his lips. All the resources of his highly-gifted nature were immediately brought into play. He wielded the powers of his majestic intelligence and the stores of his spacious imagination with consummate ease and mastery. His gestures rose into commanding dignity, his words flowed fast and free, and nothing could resist the winning sweetness of his tone. The people swayed hither and thither before the breath of his mouth. "When I throw him," said his political antagonist Thucydides, "he swears he has never been down, and even persuades the populace to believe it." In fact, he was, as his contemporaries called him, a real *Olympian*. He thundered and he lightened, and darted from his tongue the bolts of almighty Jove. Nor was the foreign policy of Pericles, though less imposing, at all less far-sighted and less successful than his internal policy. He managed to take no active part in the expedition which resulted in the defeat of the Athenians at Tanagra in 457 B.C. The disastrous inroad of Tolmides into Bœotia in 447 B.C. was stigmatized with his disapproval at its very outset; and his remark on that occasion, that Time, the best of all counsellors, would corroborate his advice, became ever memorable. His measures were also successful in saving the city in 445 B.C. from a threatened revolt of her tributaries, and a simultaneous invasion of the Lacedæmonians. Bribing the Spartans to return in peace to their own country, he concentrated all the strength of the state against the factious Eubœans, brought them to terms of submission, and thus crushed a dangerous insurrection in the bud.

It was about 444 B.C., when Pericles had become absolute master of the Athenian destinies, that the most comprehensive and most magnificent schemes of policy that were ever entertained by any heathen statesman began to pass before his mind. The greatness of Athens, he thought, must be made to depend upon the concentrated influence of every excellence. She must be at once a fortress of strength, a city of palaces, an abode of refinement, and a temple of the gods. Her friends must be fascinated by her beauty and attractions; and her enemies must be overawed by her splendour and majesty. Her citizens and dependents must love and admire her as a cherishing and peerless mother; and all Greece must reverence and obey her as a stately mistress and an accomplished teacher. The first measure of Pericles for the execution of this great plan was to establish the political superiority of the city. Continuing the Athenian policy of exacting tribute in lieu of military service from the rest of the Hellenic confederacy, he drained the resources of the other Greek cities, and amassed the money within his own. Urging as a plea that Athens, if she protected the independence of Greece, might use this money for any purpose whatever, he employed it in rearing up the fabric of the national strength. A third long wall was built to the Piræus, in order that the communication between the city and its port might be rendered more secure. A fleet of sixty galleys was sent out to sea for eight months annually, in order that the sailors might be inured to service, and the ships be kept ever ready for action. Several colonies were planted to draw away the surplus population from the city, and to extend the commerce and influence of the state. At the same time, the right of Athens to arbitrate in all important disputes between her subject allies was pertinaciously claimed; so that in 440 B.C. the island of Samos, after a blockade of nine months, was reduced and punished for setting at nought this asserted supremacy. Nor, while Pericles was thus strengthening the outward fortifications, did he neglect to attend to the interior arrangements of the city. He set all the arts into their fullest activity to make it a theatre of beauty, pleasure, and refinement. Solemn festivals and religious pageants were prepared to relieve the attention and fascinate the eye. The great dramas of Æschylus, Sophocles, and Euripides were employed to stir the imagination and elevate the soul. But it was the illustrious Phidias and his able coadjutors that were specially honoured to complete the beautiful and sublime spectacle. At their command, the genii of painting, and sculpture, and architecture were summoned to fabricate a gorgeous crown for this queen of cities. Accordingly, up on the brow of the Acropolis, with wonderful rapidity, were reared two grand and elegant structures of white marble—the Propylæa, with its lofty porticoes, and the Parthenon, the most exquisite fabric that Grecian genius ever designed. The inner walls of these edifices were crowded all over with painted and sculptured figures; the intermediate ground was studded with statues; and towering over all, and visible to the mariner as he doubled the distant Cape of Sunium, rose the colossal image of Athene Promachos, with shield upraised and javelin balanced, as if in the act of protecting her favourite city, the seat of her worship and her name.

While these great works and enterprises raised Athens to a transcendent height of power and glory, they were only the occasion of involving the latter years of their great author in trial and difficulty. The Spartans, jealous of the supremacy which the Athenians were establishing under his administration, began to organize a conspiracy, and to meditate the Peloponnesian war. His political adversaries, taking advantage of the excitement produced by coming hostilities, commenced to assail him. They vented severe criticisms upon his government, charged him with the design of assuming the tyranny, and condemned his defensive attitude towards the hostile Lacedæmonians. The comic

poets threw every available scandal at his head, and made him the butt of every species of ridicule. There were some who, not content with attacking him directly, aimed at him indirectly by assailing his connections and acquaintances. His friend Phidias was arraigned for introducing his portrait on the shield of one of the statues of Minerva, and was thrown into prison, and left there to die. His paramour, the notorious Aspasia, was accused of pandering to his licentiousness, and was only acquitted after he had descended to plead for her life with tears and entreaties. His aged teacher also, Anaxagoras, was charged with overturning the national religion, and was sentenced to pay a fine, and to go into banishment. Yet the great statesman, completely mailed in his own probity, withstood these darts of calumny, and addressed himself to meet the attack of the Peloponnesians, who had now declared war. His tactics were directed by a policy as thorough-going and effective as it was cautious. Knowing that the enemy was superior in land forces, he collected all the moveable property of the Athenians within the walls of the city, and contented himself with assuming a defensive attitude towards the advancing invaders. Knowing also that Athens was the undisputed mistress of the seas, he sent out a fleet to make descents and reprisals upon the coasts of the Peloponnesus. This system of strategy was carried on efficiently during the first two years of the war. It might have been continued with the same result, and might have brought hostilities to a successful issue, had not an unforeseen disaster occurred to remove the able general and administrator. A plague broke out in Athens, raged with dreadful malignity, and threw the citizens into a ferment of irritable discontent. Pericles was made the scape-goat of all the national calamities, and was condemned to suffer the unreasonable ill-humour of the ungrateful populace, and the indignity of being fined. A series of private afflictions at the same time fell fast and fearfully upon him. Many of his relations and political friends died of the epidemic. His family also gradually wasted away. At length his only surviving legitimate son was carried forth lifeless. The stoical fortitude of the solitary old man now broke down. As he placed the funeral garland upon the head of the ill-starred youth, he burst into a flood of tears, and sobbed aloud. He resumed his public duties; but it soon became evident that public ingratitude and domestic misfortune had prostrated his strength and spirit. About the middle of the year 429 B.C., a slow fever seized him, and he lay down upon his death-bed. As the closing hour drew near, his attendants, thinking him in a stupor, stood round the couch recounting the deeds of the great soul that was preparing to depart. "You have forgotten," muttered he, "my greatest praise: you have not noticed that no fellow-citizen has ever put on mourning on my account." These were the last words of this great Athenian.

The authorities for the biography of Pericles are Plutarch and Thucydides. (See also the Grecian Histories of Grote and Thirlwall.)

PERIGEE (περί, *near*, γῆ, *the earth*) is that point of the moon's orbit at the least distance from the earth. In this sense it is opposed to *apogee*. (See Astronomy.)

PÉRIGUEUX, a town of France, capital of the department of Dordogne, is built in the form of an amphitheatre on the right bank of the Isle, here crossed by a fine bridge, 68 miles E.N.E. of Bordeaux, and 296 S.S.W. of Paris. It consists of two parts, the town proper and Puy-Saint-Front. The former of these is substantially though irregularly built of freestone. The streets are narrow; and many of the houses are curiously ornamented. The ancient ramparts are now replaced by boulevards; and a fine public walk in the highest part of the town commands a beautiful view of the valley of the Isle. The cathedral of St Front is a very remarkable edifice; it is an exact copy of St Mark's at Venice, having five domes, and a tower 197 feet high at the W. end. The prefecture of Périgueux is a fine edifice of modern date; and the church of the Jesuits is also a beautiful structure. There are here a public library, containing 16,000 volumes, a museum of antiquities, court-house, barracks, hospital, theatre, and other buildings. In one of the suburbs stands a round tower of Roman origin, 100 feet high; also a Roman arch and amphitheatre. The manufactures principally carried on in the town are those of paper, woollen fabrics, hosiery, leather, cutlery, brandy, and the celebrated pies of Périgueux, made of partridges and truffles, and which form a considerable article of export. An active trade is carried on in flour, salt, iron, wood, pork, groceries, &c. Périgueux occupies the site of the ancient Vesunna, which was at the time of the Roman invasion the capital of the Petrocorii. Under the empire it was a place of no small importance, as it stood at the junction of five roads and was strongly fortified. Périgueux, along with Aquitaine, was ceded to the English by Louis IX. After having been recovered by the French, the town was again lost; but it was finally taken from the English by Charles V. During the civil wars of the Reformation it was a stronghold of the Protestants till the year 1581; and it was not till 1653 that it came into the power of the Crown. Pop. (1856) 13,291.

PERIHELION (περί, *near*, ἥλιος, *the sun*) is that part of the orbit of a planet or comet at its least distance from the sun. In this sense it is in opposition to *aphelion*. (See Astronomy.)

PERIM, or Mehun, an island in the Strait of Bab-el-Mandeb, off the coast of Yemen in Arabia, and having its southern extremity in N. Lat. 12. 38., E. Long. 43. 23. In form it is oval, 3½ miles in length from W.N.W. to E.S.E., by 2½ in breadth; and it divides the entrance of the Red Sea into two channels, called the Great and Little Straits respectively; the former, between Perim and the African coast, being 13 miles broad, and the latter, formed by the island and Cape Bab-el-Mandeb, 1¾. The Little Strait is the one most frequently used by vessels entering the sea, as it is quite safe, though varying from 7 to 13 fathoms in depth, and as it affords good anchorage; whereas in the Great Strait, where the depth varies from 13 to 25 fathoms, there are only a few places where anchorage can be obtained; but during the night, with a favourable breeze, the wider passage is to be preferred. The island is a bare black rock, without water, and almost entirely destitute of vegetation; but it has on the S.W. side a magnificent harbour, more than 1½ mile in length, and from a half to three quarters of a mile in breadth, with a depth of 7 or 8 fathoms. It is capable of containing forty men-of-war; and the entrance is safe, being about half a mile wide, and 16 fathoms deep. The island of Perim commands the entrance of the Red Sea; and for this reason it has been twice occupied by the British in order to defend the approach to India. The first occasion on which it was occupied was in 1799, in order to guard against the designs of the French, who were then in possession of Egypt. The island was, however, abandoned in 1801, when that danger had passed away. In recent times, the project of the Suez Canal has given rise to similar apprehensions; and the island was a second time occupied, February 1, 1857, and formally taken possession of on the 14th of the same month. Since that period fortifications have been erected on the island, under the guns of which all vessels have to pass that sail through the straits.

PERIMETER, the bounds or limits of any figure or body. The perimeters of surfaces or figures are lines, and those of bodies are surfaces. In circular figures, instead of perimeter, we say circumference or periphery.

PERIOD, in *Astronomy*, is the time occupied by a star or planet in making a revolution round the sun, or the

duration of its course till it return to the same part of its orbit. (See ASTRONOMY.)

PERIOD, in numbers, is applied to the recurring part of a circulating decimal.

PERIOECI (περίοικοι) is an old geographical term used to denote those who dwell under the same latitudes but under opposite longitudes, just as *antœci* (ἄντοικοι) meant those under the same longitude but opposite latitudes, and *antipodes* (ἀντίποδες) those under opposite latitudes and opposite longitudes.

PERIPATETICS (περιπατέω, *I walk about*), a term applied to the disciples of Aristotle, because he taught them while *walking* in the περίπατος, or promenade of the Lyceum at Athens. *Peripatetic* accordingly came to be equivalent to Aristotelian. (See ARISTOTLE, and ARISTOTELIAN PHILOSOPHY.)

PERIPHERY (περιφέρω, *I carry round*) signifies, according to the Greek use of the term, the circumference of a circle. It is usually applied, however, by the moderns both to rectilinear and to curvilinear figures.

PERIPHRASIS (περί, *about*, φράζω, *I speak*) signifies properly circumlocution, and is applied to that figure of rhetoric in which more words are used than are necessary to express the idea, with the design of avoiding common and trite modes of expression, and thus giving dignity and elevation to the discourse. The periphrasis is of great use on some occasions; and it is often necessary, to make things be conceived which it is not proper to name. It is sometimes polite to suppress the names, and only to intimate or allude to them. These turns of expression are also particularly serviceable in oratory; for the sublime admitting of no direct citations, there must be a compass taken to insinuate the authors whose authority is borrowed. A periphrasis, by turning round a proper name in order to make it understood, amplifies and raises the discourse; but care must be taken that it be not too much swelled nor extended *mal à propos*, in which case it becomes flat and languid.

PERIPNEUMONY (περί, *about*, πνεύμων, *the lungs*) signifies properly an inflammation of the substance of the lungs, as distinguished from pleurisy, or the inflammation of the membrane which invests the lungs.

PERISTALTIC (περιστέλλω, *I involve*) is an epithet given to a vermicular spontaneous motion of the intestines, performed by the contraction of the circular and longitudinal fibres of which the fleshy coats of the intestines are composed; by means of which the food, chyme, chyle, fæces, &c., are kept moving towards the termination of the alimentary canal.

PERISTYLE. See Glossary to ARCHITECTURE.

PERITONEUM (περιτόναιον, from περί, *about*, and τονόω, *I stretch*) is the fine membrane which lines the inside of the abdominal cavity, and envelopes every portion of the intestines. Inflammation of the peritoneum is called *peritonitis*.

PERJURY is defined by Sir Edward Coke to be a crime committed when a lawful oath is administered in some judicial proceeding, to a person who swears wilfully, absolutely, and falsely, in a matter which is material to the issue or point in question. In ancient times it was in some places punished with death; at other periods it made the false swearer liable to the punishment due to the crime which he had charged the innocent person withal; and at others, again, it subjected him to a pecuniary fine. But though it escaped human, yet it was thought, amongst the ancients in general, that the Divine vengeance would most certainly overtake it; and there are upon record many severe inflictions believed to be from the hand of God, as monuments of the abhorrence in which this atrocious crime is held by the Deity. (See OATHS.) Perjury is a misdemeanour at common law, and is punishable by fine and imprisonment, and by transportation for a period not exceeding seven years. Owing to the painful increase of perjury, all courts of justice, civil or criminal, down to petty sessions, are now empowered by stat. 14 and 15 Vict., c. 100, § 19, forthwith to commit and direct to be prosecuted any one appearing to them to be guilty of perjury.

PERIZONIUS, JACOB, a learned Dutchman, was born at Dam, in the province of Groningen, in 1651; studied at Deventer, and afterwards at Leyden. He applied himself with great ardour to philology and history; and in 1674 was appointed rector of the gymnasium at Delft. In 1681 he removed to the academy of Franeker as professor of eloquence and history, and accepted the chair of history, eloquence, and the Greek language in the university of Leyden. During his whole life he plied his pen with great industry in connection with his favourite pursuits. But his assiduous and uninterrupted labours at length undermined his health, which was naturally delicate, and after languishing for some time in a hopeless condition, he died at Leyden on the 6th of April 1715.

Perizonius, though a man of an amiable and obliging disposition, was nevertheless sensative, and fond of disputation. He engaged in several keen controversies, particularly with Ulric Huber, professor of law at Franeker, on the sense of a passage in the Epistle of St Paul to the Philippians; with Francius, professor of eloquence at Amsterdam; with James Gronovius on the death of Judas Iscariot; with John Leclerc, on the subject of Quintus Curtius; and with Kuster on the *æs grave* of the ancients.

The works of Perizonius all display erudition, but are deficient in order and method Besides good editions of various authors, he wrote *Animadversiones Historicæ*, Amsterdam, 1685, in 8vo; *Q. Curtius Rufus in integrum restitutus, vindicatus*, Leyden, 1703, in 8vo; *De Doctrinæ Studiis, nuper post depulsam barbariem diligentissime denuo cultis et desideratis, nunc vero rursus neglectis fere et contemptis*, Leyden, 1708, in 8vo; *Rerum per Europam sæculo XVI maxime gestarum Commentarii Historici*, ibid. 1710, in 8vo; *Origines Babylonicæ et Ægyptiacæ*, Leyden, 1711, 2 vols. 8vo,—a work full of curious and interesting remarks on the chronology of Egypt, in opposition to Marsham, Usher, Capell, Pezron, and some other chronologists; *Opuscula Minora, Orationes atque Dissertationes varii et præstantioris argumenti*, Leyden, 1740, 2 vols. 8vo, preceded by a Life of Perizonius, and a catalogue of the manuscripts which he bequeathed to the library of Leyden. Amongst the works edited by this able scholar may be mentioned the *History of Ælian*, 1701, in 2 vols. 8vo; and the *Minerva of Sanctius*, 1714, in 8vo.

PERLEBERG, a town of Prussia, in the government of Potsdam, on the Stepnitz, 73 miles N.W. of Berlin. It contains a Protestant church and chapel, courts of law, and public offices, as well as manufactories of cloth, chicory, and beer. A much-frequented market for flax is held here. Pop. 6438.

PERM, a government of Russia, lying partly in Europe and partly in Asia, between N. Lat. 56. 30. and 61. 30., E. Long. 53. 20. and 64. 10., and bounded on the N. by the governments of Vologda and Tobolsk, E. by that of Tobolsk, S. by that of Orenburg, and W. by that of Viatka; length from N.W. to S.E., 520 miles; breadth about 400; area, 129,100 square miles, being more than double that of England and Wales. It is divided into two parts by the Ural chain, which traverses it from N. to S., forming the boundary between Europe and Asia. Of these parts, the eastern or Asiatic is considerably the smaller. The mountains rise very gradually and almost imperceptibly; the loftiest summit in this government being that called Pavdinskoi Kamen, which is more than 6000 feet above the level of the sea. The principal pass across the Urals is that which leads from Perm by Kungur and Yekaterinenburg to Tobolsk. A large portion of the surface is occupied with mountains, which are for the most part wooded, the woods containing in many places extensive marshes. The eastern portion of Perm is watered by the Sosva, the Tura, and the Sceth, tributaries of the Tobol, which itself discharges its waters by the Obi into

the Arctic Ocean. The principal river W. of the Ural chain is the Kama, an affluent of the Volga, which flows in a winding course through the country from N. to S., and receives many smaller streams. There are also numerous lakes in the government, most of them lying in the eastern portion; and mineral springs exist at various places. The southern part of the government, on the European side, is generally fertile and well cultivated, but the other portions are better fitted for pasture than for agriculture; and a great part of the land is allowed to lie uncultivated. There were in 1849, 6,948,992 acres of arable land, 5,382,283 of meadow land, 53,818,205 of wood, and 2,181,887 of waste land, in the government. The quantity of corn of all kinds raised in the same year was 34,086,933 bushels, and that of potatoes, 922,184 bushels. The corn produced is not, however, sufficient for the supply of the inhabitants. Rye, barley, and oats are the chief kinds of grain; flax is also grown. In the forests, of which nearly a half belong to the Crown, the pine, the larch, and the lime are the chief trees; the oak, the elm, the cedar, and others abound in the south-eastern parts. The climate in the northern and in the mountainous regions is cold and rigorous; on the higher summits snow lies for a great part of the year. The forests of the country abound in game, and the rivers in fish. Fur-bearing animals are also numerous. Of domestic animals the government contained in 1849, 731,693 horses, 615,277 horned cattle, 889,437 sheep, 296,427 swine, and 40,164 goats. The chief riches of Perm are its minerals, which are extensively worked, and afford employment to a vast number of the inhabitants. Gold, silver, platinum, iron, copper, lead, together with salt, marble, loadstone, diamonds, and precious stones, are the principal produce of the mines. The timber of the forests is extensively used for fuel in working the mines. The following table exhibits the quantity of different metals obtained in 1855 from the principal mines belonging to the Crown in this government:—

	Gold. Lb. troy.	Copper. Cwt.	Iron. Cwt.	Platinum (1854.) troy weight.
Yekaterinenburg......	1346	...	59,311	...
Bogossloosk.	1760	6148	...	8 lb. 9 oz.
Perm	...	5352	...	...

The manufactures in the government are inconsiderable, except those immediately connected with the mines. Cloth, leather, soap, candles, glass, &c., are manufactured; and trade is actively carried on, not only on account of the facility of conveyance by the Kama and its tributaries, but on account of the numerous fairs that are held, many of them in the large towns. About three-fourths of the population are Russians, and the remainder are descended from the ancient inhabitants of this country, and various Tatar tribes. The religion of the vast majority is that of the Greek Church; there are, however, 78,204 Mohammedans, and 9422 heathens, besides small numbers of Protestants, Roman Catholics, and Jews. The governments of Perm and Kazan are under a single military governor. In regard to education, the country is in a low state; it is under the superintendence of the University of Kazan. Perm is divided into twelve circles, and contains 1,741,746 inhabitants.

PERM, the capital of the above government, stands on the right bank of the Kama, which here receives the small rivers Danilicha and Jagoshicha, 220 miles W. of Tobolsk, and 322 N.E. of Kazan. It is environed on three sides with thick woods; and is well and regularly built, chiefly of wood, having straight and broad streets. It is the seat of an archbishop; and contains nine churches, a convent, several schools of various kinds, and hospitals. There are here extensive foundries, and refining-works for copper and iron, which are obtained in abundance from the mines in the vicinity. Trade and navigation are actively carried on. Pop. (1851) 13,262.

PERNAGOA, a town of Brazil, province of Piauhy, stands on the E. side of a large lake of the same name, 250 miles S.S.W. of Oeiras. It is the seat of a justice of the peace; and contains a fine church. Some trade is carried on in tobacco grown in the vicinity, and in horses and mules. Pop. 4000.

PERNAMBUCO, a province of Brazil, lying between S. Lat. 7. and 11., W. Long. 34. 50. and 43., is bounded on the N. by the provinces of Ceara and Parahiba, N.W. and W. by that of Piauhy, S. by those of Bahia and Alagoas, and E. by the Atlantic; area, 61,633 square miles. It consists of two distinct regions, one lying near the coast, and the other on the table-land of the interior. The coast, which is fringed with coral reefs, is low and uninteresting, and the adjacent country level; but farther from the sea there is a succession of hills and dales, and still farther to the W. the ground becomes stony and sterile, as it rises into the table-land which is known by the name of the Serrao de Pernambuco. This region forms a part of the table-land of Brazil, and consists in a great part of salt steppes, though in some parts there are excellent pasture-lands and fields of cotton. The principal mountains in the province are those of Borborema, which form its northern and western boundary; and the most important river of the province, or of any other in Brazil belonging wholly to the country, is the San Francisco, the largest stream that falls into the Atlantic between the Amazon and the Plata. It only forms part of the southern boundary of Pernambuco; and the affluents it receives here are so few and insignificant that the country is in general very dry and sterile. Some gold is found here, and excellent marble might be quarried. The forests yield abundant supplies of timber of various kinds suitable for ship-building, for carpentry, and for ornament. Dye-woods are also obtained. The climate of Pernambuco is hot and moist in the interior, but more agreeable in the maritime district. The soil of the latter is in many parts rich and fertile, producing cotton, sugar, cocoa, maize, mandioc, and a variety of fruits, medicinal herbs, and vegetables. Manufactures can hardly be said to exist in Pernambuco; but there are sugar-works and distilleries. The trade of the province is considerable, and is chiefly carried on through the port of Pernambuco. The province appoints six senators and thirteen deputies to the legislature. Pop. (1856) 950,000.

PERNAMBUCO, the capital and principal seaport in the above province, stands on the Atlantic, at the mouth of the Capibaribe, 210 miles N.E. of Bahia; S. Lat. 8. 5., W. Long. 34. 52. It consists of the towns of Pernambuco proper, or Recife, and Olinda, which are about 3 miles distant from each other. (See OLINDA.) The former stands upon a flat, and is divided into three parts, occupying respectively a peninsula, an island, and the continent. Recife, or Pernambuco properly so called, is built upon a peninsula which extends to the southward of Olinda. This is the most mercantile part of the threefold city. S. Antonio stands upon an island or sand-bank formed by the arms of the Capibaribe, being connected with Recife by a long bridge almost entirely constructed of stone. The third division of the city is situated on the mainland, to the westward of the other two, and is joined to them by a wooden bridge, considered as the largest in Brazil. This portion of Pernambuco is called Boa Vista, where the richer inhabitants reside. The appearance of the country, when Pernambuco is approached by sea, is described as charming. The hills are clothed with wood, gradually rising towards the interior; but none of them is of any considerable height. Recife contains regular though narrow streets, and houses of brick, three or more storeys in height. Besides several churches, there stand here the custom-house and the residence of the port-admiral; but the most of the provincial authorities reside in S. Antonio, where

the streets are broad, and the houses large, the ground floors being generally occupied with shops. Among the public buildings here are the treasury, town-hall, prison, barracks, governor's palace, &c. There are several public squares, and the general appearance of this quarter is very lively. The principal street of Boa Vista is broad and handsome, and there are here many elegant buildings. A long embankment connects the sand-bank and town of S. Antonio with the mainland at Affogados, to the south and west of Boa Vista. The position of Pernambuco, on the most easterly point of South America, renders its harbour one of much importance; and the nature of the harbour is no less favourable for commercial purposes. It is formed by a singular reef, probably of coralline structure, which extends for 1500 miles along the Brazilian coast, from the province of Bahia to that of Maranhao. This remarkable reef at the top is scarcely sixteen feet in breadth. To a great depth on the outside it slopes off more rapidly than the Plymouth breakwater, but it is perpendicular within; thus forming a magnificent natural bulwark or breakwater, within which the ocean is as still as a mill-pond. In some parts it sinks under water, and there are numberless breaks, by which a communication with the sea is laid open. The harbour, which is well protected from the sea by the reef, has two deep and safe entrances; but there is a bar of sand within it, which, even at spring tides, does not admit vessels drawing more than 15 feet. This might, however, be removed by dredging. The anchorage is about half a mile in length, and of breadth sufficient to admit four rows of vessels. The harbour is defended by forts; and there is a lighthouse 80 feet high, visible to a distance of 16 or 17 miles. The commerce of Pernambuco is very important, the exports consisting chiefly of cotton, sugar, rum, hides, and dye-woods; and the imports, of cotton and linen cloth, hardware, cutlery, silks, wine, flour, cod, &c. The trade has been on the increase for some years. Pernambuco was much improved by the Dutch, who were in possession of it from 1630 to 1654. The population of the town is 12,000; of the district, 38,000.

PERNAU, a fortified seaport-town of European Russia, in the government of Livonia, stands on a flat sandy heath at the mouth of the Pernau, on the Gulf of Riga, 102 miles N.N.E. of Riga. It is well and regularly built; and contains two Lutheran and one Greek church, several schools, an orphan hospital and various other benevolent institutions. The harbour has a bar at its mouth, which obstructs the entrance of large vessels; but, notwithstanding, there is a considerable trade carried on in corn, flax, hemp, timber, leather, &c. From its low situation, it is exposed to inundation. Many remains of antiquity have been discovered in the neighbourhood of Pernau. Pop. (1849) 5740.

PÉRONNE, a town of France, in the department of Somme, on the slope of a hill in the midst of marshes, on the right bank of the Somme, 30 miles E. of Amiens. It is strongly fortified, and has a ruined castle, in one of whose towers Charles the Simple died in captivity, and Louis IX. was imprisoned by Charles the Bold of Burgundy. There are two suburbs; and the houses are well built. The chief buildings are the church of St John (a fine Gothic edifice), an ancient belfry, a town-hall, convent, hospital, theatre, and college. Manufactures of woollen and cotton stuffs, lawn, cambric, leather, sugar, and other articles are carried on here; and there is some trade in grain, wool, and brandy. Péronne was a place of much importance in the middle ages, and bore the name of *La Pucelle* ("The Maiden City"), as it was never captured till Wellington took it eight days after the battle of Waterloo. Pop. (1856) 4102.

PERORATION (*peroro*, I wind up a speech) is the concluding portion of an oration, in which all that the orator had insisted on throughout his discourse is urged afresh with greater vehemence and passion. The peroration consists of two parts; the recapitulation, in which the substance of what was diffused throughout the speech is briefly collected, and summed up with new force and weight; and the appeal to the passions, which is so peculiar to the peroration that the masters of the art call this portion *sedes affectuum*.

PÉROUSE, Jean-François Galaup de la, a distinguished French navigator of the eighteenth century, was born in 1741 at Albi, in the department of Tarn. After passing through the marine school, he entered the navy; and in 1756 was made a midshipman. Three years later, he took part in the battle of Belleisle, was wounded, taken prisoner, and carried to England, where he was detained till the peace of 1763 set him free. On returning to France, he rose through the various grades of promotion, served in the East Indies from 1773 to 1777, and when war again broke out with England in 1778, he signalized himself by several brilliant exploits. In 1782 he was sent to destroy the English settlements on the shores of Hudson's Bay. He took and destroyed Fort York, which he found undefended. Hearing that some of the garrison had fled into the woods, and were in danger of perishing from cold and hunger, or at the hands of the savages, he humanely left a supply of arms and provisions for their use. The only things of value that La Pérouse found in the fort were the papers of the governor, which, when claimed as private property, he promptly restored. When peace was restored in 1783, the French, taking up the idea of maritime discovery from their late rivals, fitted out an expedition to the Pacific. The chief command of the squadron (which consisted of two frigates, Boussole and Astrolabe) was given to La Pérouse. Setting sail from Brest on the 1st of August 1785, he doubled Cape Horn, coasted along the shores of South America, turned aside to the Sandwich Islands, and setting sail thence, spent the autumn of 1786 in exploring the coasts of Upper California. He then steered across the ocean to China; discovering Necker Island on the way, and examined the almost unknown coasts of Eastern Asia as far as Avatcha in Kamschatka, where the orders of the Russian empress procured him a kindly welcome. From this point he despatched his comrade De Lesseps overland to France with his diaries, maps, plans, &c. Leaving Avatcha towards the end of 1787, La Pérouse turned his prow to the Navigator Islands, where he lost an officer and twelve men in an encounter with the natives. To refit in peace, he next sailed to Botany Bay, where the English were then establishing their first Australian colony. Here he brought down the narrative of his travels to the latest date, and transmitted it to Europe, with a letter, in which he gave a short sketch of his plans for the future. From this time he was never again heard of. Various expeditions were sent out in quest of him, but without effect. His fate was involved in mystery till the year 1826, when an English seaman, Captain Dillon, came upon the wrecks of his squadron in the island of Wanikoro (or, as it is called by the French, Ile de la Recherche), one of the Queen Charlotte Islands. The relics, consisting of cannons, anchors, &c., were brought home, and deposited in the national galleries of the Louvre, where they are now preserved. La Pérouse's journals and letters were published at Paris in 1797, in 4 vols. 4to.

PERPENDICULAR. See Geometry.

PERPIGNAN, a town of France, capital of the department of Pyrenées-Orientales, stands, partly on the slope of a hill, and partly in a level plain, on the right banks of the Tet, at its confluence with the Basse, about 6 miles above its mouth, and 80 miles S.W. of Montpellier. It guards the passage between Spain and France by the Eastern Pyrenees, and is now one of the most strongly fortified places in France, the defences having been much improved since 1815. In form it is nearly oval, being

about 2 miles in length by 1 in breadth. The defences consist of a strong citadel, standing on the hill to the S. of the town, and separated from it by a wide glacis; by ramparts, bastions, redoubts, covered ways, &c. The inner ramparts of the citadel were erected by the Emperor Charles V., and the outer ones by Vauban. As the province of Roussillon, of which Perpignan was the capital, belonged to Spain till its cession to France in 1659, it is not to be wondered that the town retains much of its Spanish character, and its inhabitants greatly resemble those of Catalonia, on the other side of the mountains. The streets, which are narrow and dirty, are in many parts covered over with awnings, and in others with the wooden balconies of the houses. These are almost all built in the Moorish style, and have *patios*, or inner courts. In the citadel are an old square tower, and the remains of a church with a curious portal. The cathedral, which was begun in 1324, consists of a wide and lofty nave; and contains a beautifully-carved altar screen, and an ancient marble font. Near this building are the ruins of the older church of St Jean le Vieux. The buildings of the ancient university contain the public library of 20,000 volumes; and the Dominican church and convent are now used as an arsenal. Besides the buildings already mentioned, there are a town-hall, court-house, barracks, custom-house, theatre, college, diocesan school, botanic gardens, and two hospitals. Woollen stuffs, lace, playing-cards, soap, brandy, and leather are the principal articles manufactured; and a considerable trade is carried on in wines, brandy, oil, silk, wool, iron, cork, &c. Perpignan is the seat of a bishop, and of courts of the first instance and of commerce. In the year 1349, when Roussillon belonged to the crown of Aragon, the university of Perpignan was founded by King Pedro. In 1474 the town was taken by Louis XI. of France; but having been restored to Spain, it was again taken by Louis XIII. in 1642; and, along with the province of Roussillon, finally ceded to France by the treaty of the Pyrenees in 1659. Pop. (1856) 19,844.

PERRAULT, Charles, was born at Paris on the 12th of January 1628, and studied at the college of Beauvais, where he distinguished himself in scholastic disputation, and in making verses. Having completed his studies, he was admitted as advocate; but Colbert soon deprived the law of his services, and, in the year 1664, appointed him first commissary for the superintendence of royal buildings. The Academy of Painting, Sculpture, and Architecture, and that of Sciences, were founded on memoirs drawn up by Charles Perrault, who had now become comptroller-general of buildings; and he was admitted into the French Academy in 1671, in the room of the Bishop of Léon. But the impracticable character of Colbert having at length wearied out his patience, he retired from his public situation, and, devoting himself to literature, produced his poem entitled *Siècle de Louis XIV.*, which appeared in 1687, and involved him in a war with the learned, by reason of his exalting the modern in comparison with the ancient authors. He defended himself, however, in the *Parallèle des Anciens et Modernes*, which appeared at Paris in 1688, and excited the antagonism of Boileau in his *Reflexions sur Longin*. In addition to the works just mentioned, Charles Perrault wrote a considerable number of poetical pieces now all but forgotten. Perrault died at Paris on the 16th of May 1703. His son Perrault d'Armacourt was the author of the well-known *Contes de Fées*, which contain the nursery classics of "Cinderella," &c.

Perrault, *Claude*, a celebrated architect, the brother of Charles, was born at Paris in the year 1613. His father, an advocate of the Parliament, caused him to study medicine, anatomy, and the mathematics; and he even took the degree of Doctor of Physic in the faculty of Paris. But Colbert having advised him to undertake a translation of Vitruvius, the studies in which he found it necessary to engage in order to understand that writer inspired him with a decided taste for architecture, and gave a new direction to his pursuits. When the Academy of Sciences was established in 1666, Perrault was admitted a member of this body, and was employed to furnish designs and building-plans for the Observatory. But this edifice, which, with all its merits, is in a heavy style, was far from giving any indication of the talents which Perrault afterwards displayed. His grand work is the palace of the Louvre, the façade of which was designed by him, and is certainly one of the noblest monuments of architecture in France. The building had been commenced, and even part of the façade raised, according to the designs of Lavau. But Colbert, dissatisfied with these, appealed to the genius of other architects; and Perrault produced a design so superior to those of his competitors that it obtained a decided preference. Perrault furnished designs for other works, particularly the triumphal arch erected at the extremity of the Rue Saint-Antoine, the foundation-stone of which was laid on the 6th of August 1670; and in all his works he displayed that superiority of genius which was first exhibited in his translation of Vitruvius, particularly in the plates with which it was enriched, and which have ever been considered as masterpieces of their kind. The first edition of this work appeared in 1673, and the second in 1684, in 1 vol. fol.; after which the translator published an abridgment in 1 vol. 12mo; and a supplement, entitled *Ordonnances des Cinq Espèces de Colonnes selon la Méthode des Anciens*, in 1 vol. fol. Of his other productions the principal are,—*Essais de Physique*, 1680–8, 2 vols. 4to, and 4 vols. 12mo; *Mémoires pour servir à l'Histoire Naturelle des Animaux*, Paris, 1671–6, in folio; *Recueil d'un grand Nombre des Machines de son Invention*, Paris, 1700, in 1 vol. 4to. Claude Perrault assisted his brother Charles in preparing the memoirs relating to the establishment of the Academy of Sciences, and that of painting and sculpture, and took a warm interest in the success of that institution. He died at Paris on the 9th of October 1688, in consequence, it is believed, of having wounded himself whilst dissecting, in the Jardin du Roi, a camel which had died of some contagious disease.

PERROT D'ABLANCOURT, Nicolas, a French translator, was born at Chalons-sur-Marne in 1606, and was called to the French bar at the age of eighteen. His disposition seems to have been impulsive and changeable. He grew tired of law in a short time, and betook himself to literature. He became fastidious about religion, and passed from Protestantism to Popery, and from Popery back to Protestantism. Nor was he less undecided as to his place of abode. He retired from Paris to Holland, left Holland to sojourn in England, returned from England to Paris, and ultimately fixed his residence at his family seat of Ablancourt. Yet, in the meantime, Perrot was steadily engaged in translating Tacitus, Thucydides, Cæsar, Lucian, Minutius Felix, the *Anabasis* of Xenophon, four Orations of Cicero, Arrian's *Wars of Alexander*, Frontinus' *Strategematica*, and the *Apophthegms* of the ancients. These translations were appreciated on their first appearance for the elegance and happy freedom with which they gave the sense of the originals. They were, however, deficient in correctness, a fault which has long since led to their complete neglect. The death of Perrot happened in 1664.

PERRY, James, an eminent newspaper editor, was born in Aberdeen in 1756, and was educated at Marischal College in his native town. His settlement in life was attended with considerable difficulty. He had scarcely begun to study law when the pecuniary misfortunes of his father threw him loose upon the world. His application for a

clerkship in Edinburgh was unsuccessful. He indeed obtained a situation in the counting-house of a Manchester merchant; but he left it at the end of two years to repair to London as a literary adventurer. Thither his ill-luck likewise followed him. It was not until many days had passed that an accident made known his literary abilities, and procured for him the situation of a stipendiary writer both to the *General Advertiser* and to the *London Evening Post*. Perry now entered upon a successful career in newspaper literature. In 1782 his skill in the profession had become so great that he was able to start and conduct a periodical called *The European Magazine*. Appointed editor of *The Gazetteer* in the following year, he conferred a great service upon the journalism of the country by introducing the custom of employing in the reporting of any public speech a series of reporters instead of one. His success at length attained its height when he became editor and joint-proprietor of the *Morning Chronicle*. He continued in that position till his death on the 6th December 1821. Perry was the author of several ephemeral pamphlets and poems.

PERRY, a pleasant and wholesome liquor extracted from pears in the same manner as cider is from apples. (See CIDER.)

PERSÆUS, a philosopher who flourished about 260 B.C., is famous for his connection with the Stoic Zeno. He was born in the same Cretan town, Cittium; settled in the same city, Athens; lived in the same house; and adopted the same opinions. So highly indeed did the teacher of the Porch favour him that, when unable through old age to accept an invitation to the court of Antigonus Gonatus, he sent him in his stead. This honour is said to have been the occasion of the death of Persæus. Appointed by his royal patron to the command of Corinth, he was slain at the capture of that city in 243 B.C.

PERSEPOLIS, an ancient city of Persia, stood near the confluence of the Medus and the Araxes, on the spacious plain now called *Merdusht*. It was one of the wonders of the East. According to Arrian and other writers, it was from the most ancient times the capital of the Persian empire. At any rate, it is almost certain that in the reign of Darius Hystaspes it began to assume an unparalleled splendour, by becoming the site of a magnificent pile of architecture. To afford a foundation for this huge fabric, there was cut out from the side of a neighbouring hill, at a great distance from the ground, an immense platform in the shape of a series of terraces. These terraces were covered with sculptured porticoes, gigantic statues, and colossal temples and palaces. Each Persian king in succession extended and enriched the magnificent structure, until it became the crown and glory of the East. The splendour of Persepolis, however, seems to have begun to decline at the time of the overthrow of the Persian empire. Alexander the Great burned a considerable part of it, including its royal palace. After the date at which, according to the Second Book of Maccabees, Antiochus Epiphanes attempted to plunder its temples, it disappears altogether from the page of history. Yet the tall white forms of several columns, standing sentinel over the remains of many temples and palaces on the solitary plain of Merdusht, still preserve the memory of the long-perished glories of Persepolis. (A full account of these magnificent ruins is given in Sir R. K. Porter's *Travels*, Vaux's *Nineveh and Persepolis*, and Fergusson's *Palaces of Nineveh and Persepolis Restored*. See also PERSIA.)

PERSEUS, the son of Jupiter and Danäe, and the grandson of Acrisius, King of Argos, was renowned in classical fable for his wonderful adventures. No sooner had he come into the world than he was doomed to face difficulty and danger. His nervous old grandfather, terrified by a prediction of the Pythian oracle, placed him and his mother into a chest, and sent them adrift down the Argolic Gulf. The wind wafted them across the Myrtoan Sea to the island of Seriphos, and they fell into the hands of Polydectes, the selfish king of the country. At the court of that prince Perseus lived until he had grown up to be a brave and godlike young man. Then his royal patron, overawed by his superior presence, and anxious to get rid of him, commanded him to set out and bring home the head of the dreaded Gorgon Medusa. To this dangerous enterprise the youth set himself with eager alacrity. His first measure was to repair to the house of the Graiæ, —three old prophetic crones, who had only one tooth and one eye for their common use. Coming upon them unawares, and snatching their eye and tooth, he compelled them, on pain of never recovering their precious organs, to mumble out where he would get the equipment necessary for his expedition. By their direction he found the dwelling of certain nymphs, and was there supplied with winged shoes to carry him through the air, and with the helmet of Hades to render him invisible. Minerva added a mirror; and the youthful hero was now ready to dare the perilous exploit. Speeding westward through the clouds, he alighted in the country of the Gorgons, a land situated on the shore of the solitary ocean, and near the abode of eternal Night. He stepped slowly forward, averting his head lest the sight of the monsters should turn him into stone, and using the mirror to ascertain what was in front of him. Suddenly there appeared in the glass the sleeping forms of the three dread Gorgons, with their snaky locks, golden wings, and brazen hands. He struck off the head of Medusa, seized it in his hand, and sped away through the air, pursued in vain by the two remaining sisters. Another adventure awaited Perseus on his flight homewards. After turning, by means of the wonder-working head, the inhospitable Atlas into a mountain, he was passing over Ethiopia when, looking down, he saw Andromeda, the lovely daughter of King Cepheus chained to a rock, and ready to be devoured by a sea-monster. He descended, slew the monster, and won the heart and hand of the liberated maiden. The remaining days of Perseus were not so eventful. After presenting the Gorgon's head to Minerva, he is said to have settled down for life as king of Tiryns, and to have occupied himself in founding the cities of Midea and Mycenæ.

PERSEUS, the last king of Macedonia, succeeded his father Philip V. in 179 B.C., was dethroned by the Romans in 167 B.C., and died in captivity at Alba not long afterwards. (See MACEDONIA.)

PERSHORE, a market-town of England, county of Worcester, in a beautiful situation on the right bank of the Avon, here crossed by a bridge, 10 miles S.E. of Worcester, and 102 W.N.W. of London. It is well built, and consists principally of one long street. The church of Holy Cross, a fine remnant of the ancient abbey church, has a transept and a high square tower of Norman architecture; while the chancel, now used for worship, is in the early English style. There is also a small old church of St Andrew, and places of worship belonging to Baptists, Wesleyan Methodists, and Mormons. National and infant schools, and a mechanics' institution, exist here. A county court is held; and there is an annual fair held on the 26th of June. Some of the people are employed in making stockings; and a retail trade is carried on. Pop. (1851) 2717.

PERSIA.

Persia. Of the countries which have been the ancient seats of mankind, not one is more famous than Persia; and late linguistic and ethnological discoveries have revived and strengthened the interest attaching to a region which, with Assyria, Armenia, Arabia, and Egypt, supplies the most ancient records of the human race. The boundaries of Persia have fluctuated more than those of any other kingdom in the world, from the period when its monarchs rose from the government of a province to all but universal empire, down to the time when they again sank into insignificance as the rulers of a second-rate Asiatic state. In illustration of this remark, the limits of the country will be noticed under three epochs,—viz., previous to the accession of Cyrus, under Darius Hystaspes, and as they now exist. In the first-mentioned period Persia nearly coincided with the modern province of Fârs.[1] It was bounded on the W. by the Persian Gulf and Susiana, or by the Gulf, and a line drawn from a little to the northward of the point where the 30th degree of N. Lat. and 50th of E. Long. intersect each other, to the S. borders of Media; on the N. by Media, which came down to the 32d degree of N. Lat; on the E. by Carmania (*Karmán*),—that is, by a crescent-shaped line from the 32d parallel and the 55th degree of E. Long., to the coast opposite the isle of Kishm in the 27th parallel; and on the S. by the Persian Gulf. Ancient Persia, then, properly so called, did not exceed 300 miles in length from N. to S., and 230 in breadth from E. to W. In the reign of Darius Hystaspes the empire had been so vastly extended that it contained all the countries between the Indus and Sir rivers, the Aral, Caspian, Black, and Ægean seas, the Mediterranean, Red Sea, and Persian Gulf, and in addition, Thrace and Egypt, with part of Libya. It must be noted, however, that the original Persia, with probably somewhat increased dimensions, was still reckoned a distinct province; for it is specially mentioned as exempt from tribute, which the rest of the empire, divided into twenty satrapies or subordinate kingdoms, was compelled to pay to the amount of 14,560 talents, or about three and a half millions of our money.[2] In the inscriptions at Behistun, Persepolis, and Naksh-i-Rustam, lists of the provinces are given, of which it will be sufficient to mention the Behistun list. It is as follows:—Persia, Susiana, Babylonia, Assyria, Arabia, Egypt, Saparda, Ionia, Media, Armenia, Cappadocia, Parthia, Zarangia, Aria, Chorasmia, Bactria, Sogdiana, Gandaria, Sacia, Sattagydia, Arachosia, Media. The Persia of the present day is bounded on the S. by the Indian Ocean and the Persian Gulf; on the W. by a line drawn from the 30th parallel along the left bank of the Shatu'l-'Arab to Muhammarah, and thence along the Kabír Kúh, or "Great Mountain," a part of the Zagros range, which forms the western boundary of Lúristân; thence, by a curving line which passes about 15 miles to the N.N.W. of Kizil Robât; and then, running 20 miles to the W. of Lake Urumiyah, touches Mount Ararat a few miles to the E. of Baiyazíd. The northern boundary is the River Aras, from Mount Ararat to within 60 miles of the Caspian Sea; thence a waving line which touches the Caspian 5 miles to the N. of Astara, in Lat. 33. 40.; and finally the Caspian Sea and the desert of Khíva from Kasan Kulí to Sharakhs. On the E., Persia is bounded by a line drawn along the 61st degree of E. Long., from Sharakhs to the 33d parallel, when the frontier curves in to the W. to about 100 miles, and returns in an easterly direction along the mountains which form the eastern boundary of Karmân, finally curving back to the W. until it meets the Indian Ocean 10 miles to the E. of Cape Jask, in Long. 58. 5.

Aspect of the country. With the exception of the provinces of Mazandarún and Gílân, and other parts of less extent, the general aspect of Persia is that of poverty and barrenness. It has been termed a country of mountains; and a large portion of its surface is certainly mountainous, diversified with extensive tracts of desert plains, in which salt is the chief production, and, in small proportion, chiefly along the banks of the rivers, with beautiful valleys and rich pasture-lands. The valleys are not generally broad, but some are of great length, being often more than a hundred miles. The greater part of the country may be described as a table-land, supported on every side by high mountains. This table-land is shut in on the W. by the lofty mountain chain of Zagros; on the N. by that of Alburj (*Elburz*), or "The Tower,"[3] which cuts off from it the provinces of Gílân, Mazandarún and Astarâbâd; and on the S. by a lower range of hills, which runs parallel to the Persian Gulf and the Indian Ocean, at a distance of from 50 to 150 miles all the way from Abúshahr (*Bushire*) to Karâchí. On the E. alone there is no continuous chain of hills until the Sulaimân and Hâla mountains are reached, in the countries bordering on the Indus; and the line of demarcation in that direction, between Persia, Afghânistán, and Bilúchistán, is not well defined. The average elevation of this plateau is nearly that of Tehrân, or 4000 feet, and seldom sinks to 3000 feet, which is the elevation conjecturally assigned to it by Fraser. Two-thirds of this table-land are said to be desert.[4] There are no rivers of any magnitude; and what streams there are, the majority of them at least, lose themselves in the sands. From Káshân, in Lat. 34., E. Long. 51. 20., the Great Salt Desert extends eastward 400 miles to Lake Zarah in Sístân, and 250 miles from Karmân northwards to Mazandarún. The sandy desert of Sigistân is of about the same extent.[5]

The aspect of the Persian mountains is peculiarly bare and forbidding, rising abruptly from the plain, and presenting nothing to the eye but huge masses of gray rock piled upon each other; and even when they are covered with a little mouldering rock, they are still without either wood or shrubs. If for about two months in spring a scanty verdure clothe their sides, it is scorched by the heat of summer, and the country soon resumes its former barren aspect, and dreary, monotonous, reddish-brown colour.[6] Nor is the appearance of the plains more inviting, consisting for the most part of gravel washed down from the mountains, or of other equally unproductive matter, in deep and extensive beds, or of a hard clay, which, where water is wanting, as in most parts of Persia, is bare and barren. "The livery of the whole land," says Fraser, "is constantly brown or gray, except during the two months of April and May." Amongst other disadvantages, Persia labours under a general scarcity of water. The rivers are few and small, and rivulets by no means common, so that irrigation can only be applied to a small portion of the land. "In the best districts," says the above-mentioned traveller, "the small proportion of cultivated land resembles an oasis in the desert, serving by contrast to make all around it more

Persia.

dreary. Plains and mountains are equally destitute of wood: the only trees to be seen are in the gardens of villages or on the banks of streams, where they are planted for the purpose of affording the little timber that is used in building: they chiefly consist of fruit trees, the noble chinar or oriental plane, the tall poplar, and the cypress; and the effect which a garden of these trees produces, spotting with its dark green the gray and dusky plain, is rather melancholy than cheering."[1]

As already mentioned, the provinces of Mazandarún and Gilân, adjoining the Caspian Sea, with parts of Azarbíján, form exceptions to this general description. These provinces are divided from the high table-land of Persia by the great range of the Alburj Mountains, which are connected with the mountains of Armenia, and with the mighty Caucasus chain, and eastward by a continuous chain, with the great ridge of the Hindú Kúh. They take an easterly course along the shore of the Caspian Sea, and send various ramifications southward; whilst other elevated ridges spring from the Caucasian Mountains, and penetrate the country in a S.E. direction, dividing the provinces of 'Irâk and Khuzistán, and extending along the shores of the Persian Gulf, and with other parallel chains farther in the interior, into the province of Makrân. The Caucasian chain forms the barrier between the empires of Turkey and Persia; it occupies the space between the Black Sea and the Caspian; and it is inhabited by barbarous tribes, who owned at any time but an imperfect allegiance to Persia, and who have been now brought chiefly under the more rigorous sway of Russia. The Alburj Mountains, whose average height is from 6000 to 8000 feet, present their loftiest face to the interior desert; yet they sweep down in a manner so gradual, that the valleys and ravines which they form are found to contain rich and fertile lands, well watered by numerous rivulets, and well cultivated and peopled. The loftiest peak of this range is Mount Demawend, which rises to the height of 15,000 feet[2], and is covered with perpetual snow; while the rest of the range is covered only from November until Midsummer. Fifty-five miles S. and by E. of the peak of Demawend, according to Ferrier,[3] is that remarkable pass, forming a strong barrier against the progress of an invader, which was denominated by the ancients the Caspian Gates, now called the Pass of Sardârí, which for 28 miles was said to be a narrow road between high rocks, through which a single chariot could scarcely pass, and where a handful of men might oppose the advance of an army. The districts at the southern base of the Alburj range are beautifully diversified with wood, water, and mountains, in their most varied forms, and present a luxuriant verdure all the year round. In the slope of the mountains opposite to Tehrân is the delightful tract of Shamirún[4] (or Sham'a-i-'Irún, "The Light of Persia"), about 20 miles in length, "containing nearly forty villages, clustered together amid gardens and groves, with streams of water from the heights above," to which all the inhabitants of Tehrân, who can afford it, resort in summer. On the northern side of these mountains, the provinces of Mazandarún and Gílán, and the district of Astarábád, are equally fruitful and productive. Mazandarún is most celebrated for its culture of rice, which is of very superior quality. In the central provinces of Fárs, 'Irák, and Khurásán, the valleys are generally level; in Azarbíján, to the W. of the Caspian Sea, they lie between a succession of eminences; and Kurdistán, to the N., is almost one immense cluster of small mountains, intersected occasionally by loftier ranges, on which extend table-lands of great elevation, and subject to extreme cold, as in other parts of Persia.[5] The mountain range which commences near Shíráz, approaches close to the sea in Long. 55., and at Cape Jask has an elevation of 5000 feet. It decreases in height as it runs eastwards. The salt deserts which occur in various parts of the country form one of the most striking objects in its scenery, and may be distinguished from the general dreariness of the country by a saline efflorescence, which is seen glistening in the rays of a fierce sun. This appearance, extending over an immense plain, varied by a black rock here and there protruding from its surface, its image contorted into a thousand wild and varying shapes by the effect of the mirage, which produces the most curious optical illusions on those wide extended level tracts, is a sure indication of the total desolation which reigns around. The Great Salt Desert, between Káshân and Tabbas, is the most remarkable of these tracts, and occupies a vast space in the centre of the country. It forms a long inlet between the district of Tehrân on the N., and Kúm on the S., commencing about E. Long. 50., and on the 33d parallel, and trenching on the districts of Káshân and Isfahân, expands after the 53d degree of E. Long. to a vast breadth, as far E. as Tabbas, and on the S. insulating Yezd. On the N.E. it extends as far as Turshíz, but with somewhat more frequent interruptions; and on the E. it is encroached on by projections from the more cultivated districts of Farah, Sabzâwâr, and Hírât. The appearance of these deserts is not altogether uniform. In some places the surface is dry, and produces plants which thrive in a salt soil; in others the saline efflorescence is seen on a crackling crust of dry earth; marshes occupy a considerable portion of this country; and there is accumulated in the winter months water, which is evaporated during the heats of summer, leaving a quantity of salt in cakes upon a bed of mud. In some places the soil is a perfectly hard-baked and barren clay; and in others, again, sand abounds, which is formed into hillocks in the shape of waves by the wind, and is so light and impalpable that it is blown aloft in clouds, as in the Arabian deserts, by the violent N.W. winds which prevail in summer, and proves dangerous, and frequently fatal to travellers.[6]

Rivers.

Persia has hardly a single river that can be termed navigable, for the Euphrates and Tigris cannot be considered as running within its territory. The Kárún, which flows into the Euphrates through the province of Khuzistán, and the Aras or Araxes in Azarbíján, which flows into the Black Sea, and the *Safíd Rúd* or White River, which falls into the Caspian, are its two largest rivers. The Kárún is the largest affluent received by the Tigris in Mesopotamia, and is formed of two streams. Of these, the Dizful rises in Lat. 33. 50., and after a course of upwards of 200 miles joins the Kárún in about Lat. 31. 40. The Kárún rises in the Yellow Mountains, part of the Bakhtiyárí range, in Lat. 32., Long. 51., near the river of Isfahân;[7] and after emerging from the hills, flows to Shustar, where it is made by a canal to pass E. and W. of the town. From the point where these streams re-unite the Kárún is a noble river, exceeding in size the Tigris or Euphrates, and is navigable for steamers. Its course hence, for upwards of 150 miles, is very tortuous, and it then falls into the Shatu'l-'Arab near Muhammarah. Its total course, reckoning from the source of the Dizful branch, is 430 miles; or from the source of the Kárún about 330. The Aras rises in N. Lat. 40. 40., E. Long. 42. 40.,[8] and flows almost due S. to Long. 44., when it turns E., until near Eriván it again

Persia.

turns S., after receiving the waters of Lake Sivan. In Long. 46. it again turns E., until in Long. 48. 40. it unites with the Kúr at Jasat. Its total course is about 750 miles. The Safíd Rúd rises in Ardelán, in N. Lat. 35. 45., E. Long. 46. 45., and flows in a N.E. direction, but with a great sweep to N.W., between Long. 48. and 49. 15., into the Caspian. Its total course is 490 miles. The Helmand cannot with any propriety be termed a Persian river, as it flows eastward of Persia, through the independent territory of Afghânistân.

The principal Persian lake is Lake Urumiyah. This lake is 80 miles in length from N. to S., and 20 miles in breadth. Its chief feeders are the rivers Aji Su, or River of Tabríz, and the Jagetu and Tatau. The Aji Su rises in N. Lat. 38. 10., E. Long. 47. 45., and after leaving the city of Tabriz, 5 miles off on its left bank, enters the Urumiyah Lake in Lat. 37. 48., Long. 45. 40. Its total course is about 180 miles. The Jagetu has a total course of 140 miles. It rises in Lat. 35. 40., Long. 46. 30., and enters the lake in Lat. 37. 13., Long. 45. 52 The course of the Tatau is about 90 miles. The greatest depth of the Urumiyah Lake is 24 feet, but the average is not more than 12. It stretches from N. Lat. 37. 5. to 38. 15., and lies 4300 feet above the sea-level. Ten miles to the W. of it is a town of the same name, the birth-place of Zartasht or Zoroaster. It contains 25,000 inhabitants, of whom 22,000 are Muhammadans, and the rest Jews and Nestorians. Several mounds of nearly 100 feet high, composed of ashes, show where the great altars were situated. The lake is now fast drying up, and around it for several miles are tracts of sparkling salt. The waters of the lake are intensely salt, and so heavy that the strongest wind has little effect upon them. If stirred by a tempest, they subside almost immediately when a lull takes place. The whole of Kurdistân is supplied with salt from this lake.

Soil and products.

The nature of the soil in Persia may be inferred from the description given by travellers of the aspect of the country. Yet it is extraordinary how vegetation thrives in the country, even with the rudest cultivation, whenever there is the smallest supply of moisture. Morier mentions that in the plain of Abúshahr (*Bushire*), which stretches into the interior from the Persian Gulf, which all travellers agree in calling a barren land, and which has no other moisture than the dews, and occasionally winter showers, the seed produces one hundred to seven; and that a sprinkling of seed, with the most superficial furrows, returns everywhere in this district abundant produce. The same traveller observed, in his journey from Tehrân to Tabríz, several spots where, by the aid of water, the country was one carpet of verdure. Water in Persia is so essential to vegetation, that almost the only species of improvement which is carried on is the construction of subterranean canals, for the purpose of conveying water to lands which are destitute of any natural supply. These canals, when they are finished, are often let at high rents. Fraser mentions one small stream which brought an annual rent of 4000 rupees, equal (the Persian rupee being valued at 1s. 4½d.) to L.375; and another canal, opened by the governor of Kázárún, and employed in irrigating a fruit-garden, was rented at five or six times that sum. The products of Persia are,—wheat of the finest quality, barley, and other grains. Rice might easily be produced in the southern provinces, were it not for the deficiency of water, of which this grain requires so large a supply. The vine flourishes in several provinces; and the wine of Shíráz has often been highly celebrated, as well as the wines produced from grapes raised upon the side of the Caucasian Mountains. The vines of Shíráz are trained as standard bushes, without any support, and are set, with some attention to regularity, from eight to ten feet asunder. The mulberry is produced in great abundance in the northern provinces of Mazandarún and Gílân, of which silk is one of the great staples, and also in other parts; and the rich and well-watered plains of Gílân and Mazandarún yield in abundance the sugar-cane, though the art of refining is not understood in this rude and semi-barbarous country. Amongst the other products of Persia which, being useful, are articles of trade, are,—gum tragacanth; assafœtida, the plant of which grows in abundance on the plains and hills near Turshíz[1] and all round the city of Hírát; yellow berries; saffron; henna, but not so fine as that of Egypt; madder roots, which grow wild upon the mountains, and are brought down for sale by the Iláts and other wandering tribes. Gazanjubín[2] ("manna") abounds in the province of Karmânshâh. It is a deposit by a green fly on the back of the leaf of the dwarf oak. The Persians mix it with flour and sugar, and make it into cakes, which are exported to all parts of Asia. In the district of Turbat Ishâk Khân, S.W. of Mahmúdâbâd in Khurâsân, opium and tobacco are produced.[3] Indigo is cultivated in Láristân, but is not so fine as the indigo of India, which is largely imported into Persia. The leaf is used for dyeing the beard, a curious fashion in Persia, as in other parts of the East. Cotton is produced to supply the internal consumption; also hemp and hops. Fruits are produced in the garden-grounds in great abundance and perfection. The date is one of the most important products, being used here, where the climate is extremely hot, as an article of food, in the same manner as in other parts of the East. Those produced at Dáláki, four stages N.E. of Abúshahr, in the province of Fárs, are celebrated over the country for richness and flavour. The other fruits are,—pomegranates, a luscious fruit here, and much superior to those which are produced in Turkey, some that Morier saw being twelve inches in circumference; sweet and water melons; the shaddock; limes; oranges, for which the climate of the high table-lands is too cold, although they grow to perfection on the plains and on the banks of the Caspian Sea; apples; pears; apricots; pistachio-nuts; walnuts; and some others. The melons of Isfahân are the finest in the world.[4] The species called Gurgâb is so large that two melons are a load for a donkey. The quinces also are very fine. Timber is scarce on the arid plains, but in more favourable situations the soil seems well adapted for the growth of wood, and indeed of trees of every description. The mountains of Gílân, Mazandarún, and Azarbíján are clothed with the finest woods, amongst which are the oak, the beech, the elm, the alder, boxwood, with thickets of wild cherry and thorns, and luxuriant vines climbing up the trunks of the trees, and hanging in wild festoons from the one to the other. These form a striking contrast to the long ranges of naked and barren mountains in the central and southern provinces. In several provinces grows the poppy, from which is made opium of a very fine quality. The liquorice-plant covers the plains of Merdasht, and the neighbourhood of Shíráz. The tamarind, which flourished near the water-courses, and several of the thorny plants that sprinkled the same districts, had been superseded, when Fraser visited these parts, by various aromatic herbs, amongst which a species of fragrant rice was abundant. The most interesting of all the plants is that which yields the gum-ammoniac. It resembles hemlock, and rises to the height of from 3 to 6 feet. It is remarkable in its season for its rich dark-green verdure; and it is then so full of juice, that on the least scratch it flows in streams to the ground, and congeals on the stalk. It is thus gathered for sale. Such vegetables as carrots, turnips, cabbages, spinach, beet-root, and the like, are common. In the more fertile parts of Persia flowers grow

Persia.

to great perfection and luxuriance; the rose, and every variety of the crocus species, primroses, violets, lilies, hyacinths, and others no less lovely than unknown.[1] Aromatic and thorny plants, and beautiful mountain shrubs, also abound, and clothe the ground in all the rich attire of luxuriant vegetation.

Mineral productions.

Notwithstanding the numerous ranges of mountains which intersect the country of Persia, its mineral resources are scantily developed, partly from ignorance of the art of mining, and partly from the general indolence of the inhabitants, owing to the discouragement of tyrannical and rapacious rulers. There are several mines in the vicinity of Yezd.[2] One of lead at Báft, on the road to Karmán, is remarkably rich, and supplies the greater part of Persia with that metal. There are also some mines of fine rock-salt, and one of green marble. According to Mr Binning,[3] "excellent coal is found in the Alburj Mountains, and is commonly used in preference to charcoal by the blacksmiths in Tehrán and in the arsenal." There are also copper, lead, and iron mines in the mountains; and copper is extracted in such quantities as to render it an article of exportation. There is little doubt that gold and silver would be obtained if proper means were applied. In fact, M. Ferrier (p. 117) expressly says that it is owing to the want of science, and of fuel and water-power, that the gold and silver mines at Davind, close to Mashhad ("Sepulchre of the Ghâzís"), are not worked to advantage. About twenty years ago a party of Scotch miners brought by Sir A. Bethune Lindsay, were employed by the Persian government in working mines in the Káradagh Mountains, which contain most extensive veins, but the short-sighted authorities put a stop to their operations when most promising. The mineral production most common in Persia is salt, which, as has been already mentioned, covers vast tracts, and occurs everywhere in great abundance. All the lakes are salt, and every considerable collection of water is impregnated with this mineral. Salt mines are also found in different parts. At Naishápúr, in the north, there is a salt mine consisting of three excavations, in each of which a vein of salt is found from 6 to 18 inches in thickness. The salt is beautifully white, and the crystals so clear that Mr Fraser could see distinctly through a mass 2 inches in thickness, as through a pane of glass. This mine pays a small rent; and the salt is highly esteemed throughout the country. One of the most remarkable productions of Persia is naphtha or bitumen, which is burned by the natives in lamps instead of oil, and also answers all the purposes of pitch, being used in covering the bottoms of the vessels which navigate the Euphrates. It is found in pits 3 feet in diameter, and from 10 to 12 feet in depth, which are gradually filled from springs. There is also another species of white naphtha, different from the other, which is found floating like a crust on the surface of the water, and affords a more agreeable light than the black naphtha. A black and liquid petroleum of an agreeable odour flows in small quantity from a mountain in Karmán; it is reserved for the use of the king, and is given away in presents. The mines are carefully sealed and guarded. The northern mountains of Persia contain considerable varieties of valuable marble; and the turquoise stone, which is peculiar to the country, is found in the rocks near the village of Mádan, 32 miles W. of Naishápúr in Khurásán. The mines which produce this stone were visited by Fraser in January 1822, who (pp. 409–420) gives a detailed account of their produce, as well as of the very rude manner in which they are worked. The hills in which these stones are found consist of a very red and brown rock. The whole range is deeply tinged with iron. The substances of which the rock is composed are a dead gray earth, heavy, hard, brown rock, soft yellow stone, and a rock which is pervaded with specular iron-ore. There are five principal mines or pits from which the gem is taken. The mode of management in these mines, which from time immemorial have furnished these highly-valued gems, is the most wretched that can be conceived.

Climate.

The climate of Persia, in which, according to its latitude, heat should predominate, is considerably modified by the height of the ground; so that, according to Kinneir, the traveller may pass in a few hours from the air of Montpellier to the cold of Siberia.[4] It is intensely cold during the winter; indeed, the highest ranges of mountains are covered with snow during a part of the year, and some of the highest peaks throughout the whole year. Demawend, in the Alburj Mountains, was seen by Morier buried in deep snow in May; and in 1810, Kinneir mentions that the mountains were covered with snow in July. Severe storms also prevail. To the N. of Shíráz, especially, cold predominates, insomuch that in the vicinity of Tehrán and Tabríz all communication is frequently cut off for several weeks between these cities and the adjoining villages. The cold commences in October, and the winter is ushered in with severe storms of snow. Fraser, after leaving Shíráz, suffered severely from cold in this month. The thermometer fell to 28°, and on the next morning, the 27th of October, to 20°; and in the following month he arrived at Tehrán, after encountering so severe a storm of snow that a traveller was carried to a caravanserai frozen to death on his horse. In January, when Fraser was at Naishápúr, which is in the N. of Persia, in about Lat. 36 25., the thermometer fell during the night to 16°, 19°, and 20°, and rose during the day to 40° in the shade; and in many parts the temperature varies between the night and the day from 64° to 25° and 26°. The cold, especially to the N. of Shíráz, continues, with short intervals of warmer weather, till March or April. At Tehrán, which is in the N. of Persia, near the Alburj Mountains, Morier describes the progress of the seasons and the vicissitudes of the temperature. On the 10th of March there was a fall of snow, followed by an intense frost. On the 23d, the mildness of spring was experienced. On the 19th of April the thermometer rose to 82° in the shade. At Shíráz, Morier mentions that after the middle of June the thermometer was scarcely ever under 100°. It then rose to 105°, 108°, and 110°. "When spring commences," says Sir J. Malcolm, "there is perhaps no spot in the world where nature assumes a more lovely garb than at Isfahán; the clearness of its streams, the shade of its lofty avenues, the fragrant luxuriance of gardens, and the verdant beauty of wide-spreading fields, combine with the finest climate to render it delightful."[5] The regularity of the seasons in this part of Persia is extraordinary, and affords a remarkable contrast to the sudden changes which take place in the northern provinces. In Abúshahr, to the S. of Shíráz, Fraser states the range of the thermometer in July to be from 103° to 109°; but during the night it remained at 90°. About the end of August the weather became cooler, and the thermometer fell to 86° and 87°, and gradually during the day to 75° and 70°. In these southern regions, which include the provinces of Karmán, Láristán, Fárs, and Khuzistán, situated between the mountains and the shores of the Persian Gulf, the heat is increased by the barren and sandy plains with which this tract abounds. The hot winds known under the name of the simoom or sirocco prevail occasionally, but are not attended with danger, owing to the narrowness of the space between the sea and the mountains. In winter and spring the climate is delightful. It is never very cold; and snow seldom falls on the southern face of

Persia.

the mountains by which these provinces are divided from the N. of Persia.[1] Upon the whole, however, the climate of this country, notwithstanding the sudden transitions from heat to cold in some of the provinces, is very healthy; the air is dry, and the atmosphere always clear, so that the brightest polished metal may be exposed to it without being rusted. Nor are the dews insalubrious; whilst at night the planets shine with a lustre unknown in the cloudy skies of the N. It seldom rains, and there are consequently none of those damp and pestiferous exhalations so common in the woody parts of Hindústán. The fertile provinces of Gílân and Mazandarún, and the district of Astarábâd, which are subjected to the periodical visitation of disease, form the only exceptions to this general character. The heavy rains which fall in these mountainous regions, stagnating in the deep forests, turn them into impassable marshes, which, becoming putrid from the quantity of vegetable matter that they receive, exhale during the heats of summer and autumn a most pestilential vapour; so that the wandering tribes of these countries fly from its influence, and prefer living on the verge of the burning sand, and carrying their water from the distant river, to the least exposure to these noxious effluvia. Those who are forced to remain suffer severely from fevers, putrid as well as intermittent, from dropsies arising from cold, rheumatic affections, palsies, and other maladies. The appearance of the people, however, Fraser remarked, did not indicate either weakness or disease, for they were remarkably stout and athletic.

Animals.

The domestic animals of Persia are the camel, the horse, the mule, the ass, the goat, sheep, cow, &c. The Persians are expert and fearless horsemen; and they have different breeds of horses peculiar to the country. The native horse of Persia has been improved, both in strength and bottom, by an admixture of Arabian blood. But the original breed, which is now restored, is a tall, lank, ill-formed, and generally vicious animal, which often vents its rage upon its neighbours or its riders by kicking or biting them. It is useful, indeed, for hard work; but is not to be compared, for the purposes of riding, with the action and docility of the Arab. There is another race of horses, reared by the Turkamân hordes, not so much distinguished by grace or beauty as by its hardiness and patience of fatigue, for which it is celebrated all over Asia. It is said to have been crossed with an Arabian breed imported by Nâdir Shâh. The native horses are noted for size and bone, which appear to be indigenous; but figure and blood they owe to their Arab progenitors. "They have," says Fraser, "large and powerful quarters, resembling those of the English horse; the shoulders are often fine; their legs clean and strong; though generally spare of flesh, what they have is firm and good;" and not being burdened with a load of fat, they support the weight of the rider for an astonishing length of time. Their powers of endurance are almost incredible. They will carry their riders for seven or eight days together at the rate of 80 or a 100 miles a day. There is also a breed of ponies, fully as remarkable, if not superior to the large horses in their powers of enduring fatigue. Such horses cost a sum of money equal in value to from L.150 to L.200 sterling, and those of the best quality from L.350 to L.400. These horses are used in plundering expeditions; and they are chiefly prized on this account for their hardy qualities. In the parched and sandy tracts of Persia exposed to great heats, camels are preferred, for carrying burdens, to other animals, and they constitute the chief wealth of the inhabitants; but in almost all the other parts of the kingdom mules are more generally used for transport, on account of their extraordinary strength and activity, and their power of enduring fatigue. Sheep are very abundant in Persia, and constitute the wealth of the wandering tribes; but the latter pay no attention to improve the breed. The dog, though esteemed an unclean animal by the Muhammadans, is yet found so useful that every prejudice has given way; and a very fierce breed is maintained by the wandering tribes, for guarding their flocks and tents, and aiding in their field sports. The desolate parts of Persia abound in wild animals, amongst which may be numbered the lion (which is seen along the woody banks of the rivers), the tiger, the wolf, the jackal, the hyæna, the fox (found in great numbers, of a white colour), the porcupine, the wild sheep, the mountain goat, the wild ass, the wild boar, the antelope, and deer in great variety. Tigers are seldom seen, but it is certain that they are to be found, as it is mentioned that the skin of a royal tiger, which was killed in the neighbourhood of Tabríz, was exhibited, and was in possession of Mr Campbell. A tiger was also seen by the shepherds at the time that he was at Tabríz; and one of the Persian princes had gone out to hunt, with a large retinue, in the hope of meeting it. The wild ass is common in Persia, but is extremely shy, and not easily caught. Morier mentions that one morning, in the desert, they gave chase to two wild asses; but these distanced the horses at such a rate that they stood still and looked behind at them, "snorting with their noses in the air, as if in contempt of our endeavours to catch them." The hunters sometimes succeed in killing them, but it requires great dexterity and knowledge of their haunts; and then it is only by relays of horses and dogs upon the track which they are known to pursue. The same traveller also observed large herds of antelopes, to which he gave chase, but could never come up except with one big with young; so great is the speed of this beautiful animal. The wild hog abounds in Persia, and is exceedingly fierce. Fraser, along with a party of well-mounted Turkamâns, joined in chasing a herd of them; and one being singled out, was assailed with swords and spears, which made no impression on his tough hide; and though wounded by a pistol-shot, he continued his flight until an old man, mounted on a powerful Turkamân horse, rode up, and wheeled rapidly round, when the steed, trained to the work, struck the hog on the head with its heels, and tumbled it over dead on the spot. The wild sheep is a very fine animal, bold, portly, and very strong; thick like a lion about the neck and shoulders, and small in the loins; covered with short reddish hair curled loosely about the neck and fore quarters, and bearing an immense pair of crooked and twisted horns.

Territorial divisions.

The northern division of Persia, or the ancient *Hyrcania*, comprehends three provinces,—Gílân, Mazandarún, and Astarábâd, which are here named as situated from W. to E. On the W. are four provinces, which, naming them from N. to S., are,—Azarbíján (the ancient *Atropatene*), Ardalân or Kurdistân, Lúristân, and Khuzistân. Of these, Lúristân is divided into the Greater and Less. On the S. are Fârs, Lúristân, and Karmân (the ancient *Caramania*); on the E. is Khurâsân, corresponding to the ancient *Aria* and *Bactria*, and including the provinces of Yezd, Tabbas, Kâen and Bírjún, Turshíz, Mashhad, Damghân, and Semnún, and the Great Salt Desert. Central Persia is named 'Irák-i-'Ajmí, and comprises on the N., Khamsah, Kasvín, and Tehrân; and S. of these, Hamâdân, Kúm, and Isfahân.

Cities and towns.

If the face of the country in Persia disappoint the European traveller, his expectations will be still less gratified by the aspect of the towns, which present to him one mass of misery, filth, and ruins; for which, forming his ideas of the eastern towns from what he has read of Isfahân, Baghdád, Shíráz, Basrá, and other famous cities, he can scarcely be prepared. He looks in vain for the hum of a crowded population and the bustle of business which ani-

[1] *History of Persia*, vol. ii., chap. xxiv.

Persia.

mate the cities of Europe. Instead of the road crowded with passengers, vehicles, and an active traffic, bordered with hedge-rows and green inclosures, and with gay habitations, he has to thread his way through narrow and dirty lanes, amidst ruins of mud walls and old buildings, amongst heights and hollows, and clay-pits that produce bricks, and high inclosures that conceal the only trees the place can boast; till at last he reaches the dilapidated walls of the city, and, entering the gateway, watched by a few squalid guards, he finds himself in a mean bázár, or more probably in a confusion of mere rubbish. There are no streets, and scarcely a house; for it is only the dwellings of the poor which are seen, the houses of the rich being carefully shrouded from the view by high walls of mud or of raw bricks; and outside of these are clustered, with the utmost contempt of order, the houses of the poor. There is scarcely room for a loaded ass to pass between the narrow passages that give access to these dwellings; and as no attempt is made to level the paths, the passenger has to make his way over all impediments, diving into hollows, scrambling amongst ruins, stumbling over grave-stones, or falling into holes, especially at night, as the only street lighted in Persia is that which leads past the prime minister's house to the palace at Tehrán.[1] The bázárs are the only thoroughfares which deserve the name of streets; and these have received merited praise from many travellers,—namely, those of Shíráz; the continuous bázárs of Isfahán, which extend for miles; some of those at Tehrán, Tabríz, &c., all of which are comparatively spacious, lofty, and built of materials more or less solid; though the majority of Persian bázárs are as wretched as the towns. These bázárs are generally arched over with well-constructed brick-work or clay, or, as in the inferior constructions, with branches of trees. Here, as in India, are collected all the different trades, the smiths, the braziers, the shoemakers, the saddlers, the cloth and chintz sellers, in their own quarter; but confectioners', cooks', apothecaries', bakers', and fruiterers' shops are dispersed in various quarters. Few houses in a Persian town exceed one storey; and the general *coup d'œil* presents a succession of flat roofs and long walls of mud, diversified, however, by gardens, with which the towns and villages are often surrounded and intermingled, and in which are seen the poplar, the cypress, and the oriental plane. Almost all the towns of Persia have some defence, consisting generally of a high mud wall, which is flanked by turrets, and sometimes protected by a deep dry ditch or a rude glacis. Caravanserais are built in every town for the accommodation of travellers, and are also found at every stage on the principal roads of the kingdom. These edifices are generally constructed of stone or brick, of a square form, and divided in the interior into separate apartments. They are surrounded with high walls and towers, as a defence against the attacks of robbers. The houses are generally built of mud, with terraced roofs; and their inner apartments are usually better than might be expected from their outward appearance. The villages are in general very rudely constructed. The common huts have often, instead of a terrace, a dome roof, in order to avoid the necessity of using wood, which is a very scarce article all over Persia, there being few trees on the arid plains.

Trades and manufactures.

Persia, though it has made no great or general progress in the mechanical arts, has nevertheless been distinguished for those finer manufactures which minister to the luxury of an eastern court. Raw silk is one of the most important staples of Persia, and it is produced more or less all over the country, but chiefly in the provinces of Gílán and Mazandarún. In the former alone the annual produce amounts to about 900,000 lb. Silk goods of a very fine quality are manufactured at Yezd; and those of Isfahán, Káshán, and Tabríz are held in great estimation, as are the velvets of these places and of Mashhad. Silk stuffs are also manufactured in Resht, Laháján, and other cities of Gílán, but, according to Sheil (p. 376), of inferior quality. Satins also are manufactured, but, as Fraser thinks, of an inferior quality; and those which are imported from China are preferred. The city of Shíráz is celebrated for its gold embroideries, though these are now surpassed in other places. Its damasked steel knives and daggers are still esteemed; and it manufactures a good deal of coarse glass-ware. The chintzes and prints which are manufactured in many places are coarse both in texture and pattern, and are only used for inferior purposes. They are nearly superseded by the printed cottons of India and Europe, particularly the latter. Calamkáns are distinguished by a pattern of wreathed flowers in gay colours, sparsely strewn upon a white, blue, red, or fawn-colour ground; they are used for inner waistcoats, linings of robes, &c., and are often of very high price. Wool is produced in great abundance all over Persia and the neighbouring countries in which pastoral habits prevail. The best wool is that of the province of Karmán, the mountains of which, hot and arid in summer, and intensely cold in winter, sustain large flocks of sheep and goats, which yield the finest wool. The wool of the sheep is of an excellent quality; and the goats produce a down which grows in winter at the roots of the hair, in the same manner as that of the Thibet or shawl goats, and nearly of as good a quality. This is spun into various fabrics, which almost vie with the celebrated shawls of Káshmír in warmth and softness, as well as in fineness and beauty of manufacture. This fine wool is found not only in Karmán, but more or less over all Khurásán and the countries to the eastward, the mountains of which are favourable to the animals which produce it. The other woollen goods of Persia consist chiefly of carpets, namads, felted goods, and a variety of fabrics of smaller importance used by the inhabitants as clothing.

Trade.

Persia carries on a trade with Turkey, Baghdád, Arabia, and the countries situated on the Persian Gulf. Of the raw silk of Gílán, amounting, as already stated, to 900,000 lb., about one-fifth part is exported to Constantinople, Aleppo, and the other cities of Asia Minor; about one-fifth is manufactured in the cities of Isfahán, Yezd, Káshán, and other towns of Persia celebrated for their silk manufactures; and the remainder is partly purchased by the Russians, and partly sent to Baghdád. Persia exports to India specie, dried fruits, dates, tobacco, wine, drugs, assafœtida, sulphur, raw silk, carpets, Karmán shawls, swords, combs, copper, saffron, &c. Horses form a considerable article of export to India. They are sent by sea from Abúshahr, where they are collected from the breeding districts in the southern provinces of Persia, and from Khurásán and the north-eastern districts by land through Afghánistán and the Panjáb; and they serve for mounting the Indian cavalry, and supplying the great private demand for riding horses by the British in India. The imports from India are cotton goods, chintzes, and muslins; though these have now been in a great measure superseded by the English, French, and German stuffs, introduced from the ports of the Levant, from India, and by way of Russia. Persia receives from India indigo, which comes chiefly by sea, by the way of Abúshahr (*Bushire*), on the Persian Gulf, or by land through the country of Afghánistán, or Balkh, to Bukhária, and thence by Hírát to Persia. Spices are also amongst the Indian imports, as well as sugar and sugar-candy, the import of which forms one of the most valuable branches of trade between the two countries. The province of Mazandarún yields a coarse sugar; and there

[1] Binning, vol. ii., p. 216.

Persia.

are many parts of Persia fitted for the growth of this article; yet the country depends chiefly on India for its supply. Gold and silver stuffs from Banâras, precious stones, Káshmír shawls, iron, lead, and copper, make up the remaining list of imports. Persia exports to Turkey grain, raw silk, tobacco, paper, cotton, lamb and fox skins, carpets, silk and cotton manufactures, Karmán shawls, and salt; and receives in return specie and European manufactures, brought from the ports on the Levant. From Europe, woollen, cotton, and silk goods are imported; also imitation shawls, gold lace, metal buttons, cutlery, watches, spectacles, spy-glasses, leather, earthenware, iron, copper, tin, quicksilver, and other articles. Iron is made in several parts of Persia; but the foreign iron is preferred, and it is imported from Russia, though it is but little used in these countries. Copper in sheets is much used, and is partly imported from Europe through Russia, and partly from India. There is a considerable demand for European silk goods, which are chiefly supplied by the French. Brocades and embroidery are also supplied from France; and Fraser mentions that of these he saw some magnificent samples at Teflis. In chintzes and printed cottons the French and German manufacturers have been more successful than the English in suiting the Persian taste. The European trade with Persia, as it is conducted at present, lies under the great disadvantage of an expensive land carriage. There are various channels through which goods may reach the Persian market. First, they may be sent through Russia, and thence be transported down the river Volga to Astracan, and across the Caspian to the Persian towns of Resht or Astarâbâd. Accordingly, the countries around Astracan are supplied with the produce and manufactures of Europe by means of this great stream; and the manufactures of Russia itself have greatly superseded ours.[1] The Russian trade across the Caspian Sea is carried on by a number of small vessels, which bring to Astracan the sturgeon cured on the coasts of Gílán and Mazandarún, besides returns of other Persian produce; and convey Russian or European goods to Resht, Lahajan, and Astarâbâd. Secondly, goods may be sent by the Mediterranean to the ports of Trebizond and Redoubt Kaleh, situated at the western extremity of the Black Sea, or to Constantinople; and a considerable quantity of European goods reach Persia by this channel; but in the course of a long route of 1200 miles to Erivân, 200 more to Tabríz, and other 360 to Tehrân,—in all 1760 miles,—they are subjected to an expensive land carriage, to arbitrary imposts in their transit through the territories of rapacious chiefs, and to occasional attacks from banditti, and are consequently brought to Tehrân at an expense of sixty-five per cent. The distance from Trebizond to Erivân is only about 140 miles, the road lying across very rugged mountains, though not worse than the roads over which much of the Persian traffic is carried on. The route from Redoubt Kaleh to Teflis, the capital of Georgia, is but 230 miles, and is through a safe country, free from imposts. Teflis, under the government of Russia, has already, like Odessa, risen to be a great mart of trade; and caravans regularly travel to Tabríz in eighteen or twenty days. European goods are now sent to this place in considerable quantities,—namely, woollen cloths, cotton, printed and plain goods, some hardware articles, some refined sugar from Great Britain, silk and cotton manufactures from Lyons, and embroideries, cloths, &c., from other parts of France. There is another more direct channel through which a supply of European goods may be sent into Persia, namely, by way of Abúshahr; and, in point of fact, British manufactures to a considerable amount, especially cottons, are imported into this place, and thence conveyed to all the southern cities of Persia.

Government and laws.

The government of Persia is a pure despotism, which is subject to no control from the influence of laws or manners, and under which every man's life and liberty are at the mercy of the sovereign. He may exalt the lowest subject to the highest rank, or he may degrade, fine, imprison, maim, or put him to death, according to his will or caprice. He is taught from his infancy to consider his subjects as created for his pleasure; he is initiated in the grossest sensuality; and, as if to train him to habits of cruelty, his preceptors are in the practice of taking him to witness executions, which in Persia are conducted with extreme cruelty, as if to steel his mind against humane feelings, and to habituate him to scenes at which other men would shudder. In general, the kings of Persia profit by these early lessons; few of them are considerate or merciful; whilst with many, according to Sir J. Malcolm, "the habit of shedding blood becomes a passion, by a brutal indulgence in which human beings appear to lose that rank and character which belong to their species."[2] Throughout the different provinces of the Persian empire chiefs and governors are everywhere seen improving upon the example of the sovereign,—beating, maiming, and rending their property from the unfortunate cultivators who are placed at their mercy. There is no such thing as any protection for life and property in any part of this country; and the officers of government everywhere rob the people, and further insult and maltreat them if they dare to complain. A monarch of Persia acknowledges no obligations but the ritual observances of his religion; and a blind superstition is thus substituted for the moral qualities of mercy, generosity, and justice. Every look being watched by parasites and flatterers, he becomes as impatient of the least opposition as he is insensible to the most devoted service. Distrust and terror reign amongst his courtiers, amongst whom falsehood, dissimulation, and specious show supply the place of truth and loyalty. They have no means of preserving the royal favour but by flattery and fawning; and hence their whole object is to deceive and pillage, and, if they can with safety and advantage to themselves, to betray their tyrant. The effects of this system may be traced through all ranks about the court, even to the lowest menial. Such is the character given of those who are attached to the various courts, and live in service with great men, including the military and other functionaries. The other classes into which the population of Persia is divided are,—those who live in towns, namely, merchants, shopkeepers, mechanics, and others; those who are engaged in agriculture; and, lastly, the clans or *íls*. The inhabitants of towns are less exposed than others to the tyranny of their superiors, and they are more industrious; and, though far from strict in their morals, they are not so actively vicious. They are, however, cunning, deceitful, false, eager after gain, and cautious and penurious. The clans are *Táts* or *Takhtah Kâpa*, "dwellers in houses,"—*i.e.*, stationary; or dwellers in tents. According to race, they are divided into Arab, Turk, Lek, and Kurd. An enumeration of these will be found in Sheil's *Persia*, p. 393. They are supposed to form half the population of the whole kingdom.

There is no class in Persia subjected to such tyranny and oppression as the farmers and cultivators of the soil. They are exposed to almost continual extortion and injustice; there is no definite limit to the amount of the demands made upon them. When the king demands money from his ministers, they have recourse to the heads of districts, who in their turn apply to the heads of villages, and these last wring it from the cultivators and farmers. Every

[1] Binning, vol. ii., p. 298.

[2] *History of Persia,* vol. ii., chap. xxvi.

tax, present, fine, or bribe, from whomsoever demanded in the first instance, ultimately falls upon them; so that the only measure of these demands is the ability to pay on the one hand, and the power to extort on the other. Yet there are exceptions to this uniform system of oppression; and when travellers have been admitted to view the Persian farmers in their houses and with their families, a degree of comfort and comparative plenty have been discovered, not quite compatible with the general tale of misery that was told. Land[1] belonging to the cultivator pays nominally one-fifth, but really one-third of the value of its produce. The crown lands are rented at one-half their produce. Landed property is hereditary; but the tax must be paid whether cultivation is carried on or not, and, in case of non-payment, the land is liable to seizure and transference to other parties. The tax is paid partly in cash and partly in kind. Though the Persian peasantry are poor, their general condition would contrast favourably with that of many of the same class in Europe. Famine is unknown; and in so thinly peopled a country the small supply of food required for the wants of the inhabitants is easily raised. The Persian peasants are civil, obliging, and intelligent.[2] The politeness of the Persians, for which they have been so much famed, seems to consist more in the observance of a troublesome routine of ceremonies, and the use of complimentary language in all the forms of eastern hyperbole, than in any real courtesy. A Persian will say to a stranger that he is his slave; that his house and all that it contains,—his horses, equipage, &c.,—all are at his service; but no one understands this in any other sense than an unmeaning form, which encumbers the intercourse of society without refining it. In their persons the Persians are handsome, active, and robust; lively in their imaginations, and of quick apprehension; but without any moral quality to attract esteem. The effects of the cruel despotism under which Persia groans, in thus degrading the character of the people, and also in checking the progress of science and of every useful art, are truly melancholy. The insecurity of life and property is the dead-weight which oppresses the country. It represses the efforts of industry; it paralyses the powers of invention, and every ingenious improvement; for no man will sow where he is not sure of reaping, or will task his ingenuity to produce what he may be deprived of the next hour. It is a common practice to kidnap the best workmen in all trades for the use of the court and great men of the provinces, who never pay the workmen they employ. Hence every one avoids the reputation of excellence, except in the commonest trades; and thus, under the benumbing influence of this frightful despotism, improvement is nipt in the bud, and every useful invention is discouraged. There is no outlay of labour or of capital in expectation of any profitable return. No speculation is hazarded which promises any future advantage. Before closing this sketch of Persian character, one marked feature must be especially noticed. The Persians are the only Asiatics who are real sportsmen. They love the chase for itself; and will ride as hard, and with as much enjoyment, as an English fox-hunter.[3]

The king of Persia has a great variety of personal duties to perform. He gives audience at an early hour of the morning to his principal ministers and secretaries, who make reports of all state transactions, and receive his commands. He holds a public levee, which is attended by the princes, ministers, and officers of his court, at which rewards are distributed and punishments awarded. He then gives one or two hours to his personal favourites, or to his ministers. After the morning is past, he retires to his inner apartments, where he is shrouded from observation. In the evening he holds a levee, and transacts business with his ministers and principal officers of state. This, however, is rather a sketch of what his employments ought to be, than of what they are. The prime minister, exclusive of emoluments, which treble the income, receives 42,000 tumâns, or L.21,000 a year; and when the Shâh is a weak and indolent prince, has paramount influence, and transacts the affairs of state as he pleases. But he is ever exposed, like the meanest subject, to degrading punishments and a cruel death. Thus Fath Ali Shâh strangled his faithful minister Hâjí Ibrâhím; and Muhammad Shâh, the late king, destroyed Mírza Takí, his brother-in-law, as well as minister, causing his veins to be opened, and leaving him to perish by loss of blood. Besides the chief ministers, the secretaries of state preside over the different offices or chambers of accounts; and regular accounts are kept of the receipts and disbursements of the whole kingdom.

Laws, and administration of justice.

The law of Persia, as in all other Muhammadan countries, is founded upon religion as contained in the Kurân, and also upon tradition. Its rules are accordingly extremely vague and imperfect, and are administered by the priesthood, who often pronounce the most corrupt decisions. Many cases are also decided by the law of custom or tradition, which, having reference to local as well as to common usages, varies in different parts of the empire, and is, if possible, a still more vague and imperfect code than the written law of the Kurân. The ecclesiastical order in Persia, as in all other countries, eagerly grasping after power, insist that the law which they administer, being divine, should take cognisance of all cases. But the ordinary courts of common law, supported by the state, have succeeded in limiting their jurisdiction to cases of religious ceremonies, cases of inheritance, marriage, divorce, contracts, sales, and all civil matters; reserving to the ordinary courts the decision of criminal cases, such as murder, theft, fraud, breaches of the peace, and other offences. The order of priests have great influence in Persia. Before the reign of Nâdir Shâh, the whole power centred in the chief pontiff, who was deemed the vicar of the Imâm, and engrossed vast wealth and influence. At the death of this high priest no successor was appointed by Nâdir Shâh, who besides seized the treasures of the priesthood in order to pay his troops. His grandson and successor appointed two persons to this high dignity, with a view of diminishing by dividing their power and influence. These priests are called Mushtâhids; and there are now usually three or four of this high dignity in Persia. They fill no office, receive no appointment, and have no specific duties, but are called by the voice of the public, from their superior learning, piety, and virtue, to be their guides in religion, and their protectors against oppression; and Sir John Malcolm observes, that they receive from the people a degree of respect and reverence to which the proudest kings would in vain lay claim. Their conduct generally agrees with the sacred character to which they owe all their importance, as they know that in deviating from the strictest purity they would lose all their influence. This order of priests exercise an important influence on the administration of the written law. Cases are constantly submitted to their superior knowledge; and there is no appeal from their sentence except to a priest acknowledged to be superior in sanctity and in learning. The sacred character of these priests gives an authority to the decrees of the tribunals over which they preside which the monarch is forced to respect. They are often effectual intercessors for mercy to the guilty; their habitations are considered as the sanctuaries of the oppressed; and "the hand of despotic power," says Sir John Malcolm, "is sometimes taken off a city because the monarch will not offend a mushtâhid, who has chosen it for his residence, but who refuses to dwell amidst violence and

[1] Binning, vol. i., p. 345.
[2] Ibid., vol. ii., p. 361.
[3] Ibid., vol. ii., p. 367.

Persia. injustice." Next in rank to these high priests there is the Shaikhu'l-Islâm, literally the "elder or chief of the faith," who acts as a supreme judge in the court of written law. One of this class resides in all the principal cities; and under him is the kâzí, who has a council of múlás or learned men as his assessors. In the lesser towns there is only a kâzí, from whom there lies an appeal, in cases of intricacy, to the kâzí of the larger towns, and finally to the supreme judge of the provincial capital. But, as in all countries such as Persia, where there is no enlightened morality, and no control of public opinion, justice is venal and corrupt; the administration of the written law by the priests is extremely imperfect and inadequate to its ends, insomuch that the suitor is deprived of every hope of justice; and it is only the administration of the customary law that offers any security, however imperfect, for justice between man and man. Even here, however, the administration of justice varies with the character of the reigning despot; and the judges, in all their various gradations, are active and just, or corrupt and cruel, as the monarch happens to be vigilant or virtuous, avaricious or tyrannical. The European ideas of honour are scarcely known amongst any class. They are all venal and corrupt; and the iniquities which they themselves practise they but feebly condemn in others. Justice is often interrupted by the clashing authorities of the different courts,—an evil which neither the sovereign nor his ministers are anxious to remedy, seeing that it adds both to their power and profit. A suit is very soon brought to a termination, and not at great cost; but considerable sums are often paid for a favourable decision. The most barbarous rules are still followed in the administration of the criminal law. In cases of murder the heir-at-law demands vengeance for blood; and when the guilt of the criminal is established, he is delivered into the hands of the injured person or his relations, to deal with him as they think fit. The punishment of crimes in Persia is fixed by the written law, or when the king interferes by his arbitrary will. Fines, flogging, and the bastinado are the common punishments of lesser offences. The disclosure of hidden treasures is enforced by tortures; and the inhuman punishment of putting out the eyes has long been practised in Persia, as in other countries of the East, on the relations of the reigning family who may aspire to the throne, or on the chiefs of tribes whom it is desirable to deprive of power, though not of life, and sometimes on the male inhabitants of a rebellious town. Criminals are put to death by strangling, decapitation, or stabbing; but in aggravated cases the most inventive cruelty is practised in devising modes of torture. In Persia, women are seldom publicly executed, but they suffer dreadful violence in the recesses of domestic tyranny. When they are of high rank, the comprehensive injustice of the East often includes them in the punishment of their husbands or fathers; and they are given away as slaves to the lowest and most infamous classes of the community, such as mule-drivers. They are also sometimes tortured, in order to force from them a disclosure of wealth which they know to be concealed.

Revenue. The collection of the revenue is intimately connected with the administration of justice, the same officer presiding over both; and this union is unfavourable to the inhabitants, as it enables the collector to prostitute the judicial power for the gratification of his avarice. Sir John Malcolm estimates, though not on any sure data, the revenue of Persia at three millions. According to Fraser,[1] the amount varies with each successive sovereign; but Sheil, who had the best opportunities of learning the truth, states it at 3,177,000 tumâns, or L.1,747,350. The public income of Persia arises chiefly from the produce of crown lands, and from a tax on land. Landed property in Persia may be comprised under the following heads:—1*st*, Crown lands; 2*d*, Those of individuals: 3*d*, Those belonging to charitable or religious foundations; 4*th*, Those granted by the king for military service. The uncultivated tracts, which form so large a portion of Persia, are not claimed as property; but every individual who constructs one of the subterraneous canals called *kanáts*, or who contrives to bring water to the surface, obtains a title to the land which he cultivates. The other titles are, inheritance, purchase, or a gift from the crown; and these rights are held sacred under all circumstances. There is, however, this peculiarity in the state of landed property in Persia, as in other eastern countries, that the cultivator shares with the proprietor in a common right to a certain portion of the soil, of which he cannot be deprived as long as he pays the customary rent. The proprietor has a title to one-tenth of the produce, ascertained by measurement, either of the surface before sowing, or of the standing crop. When the proprietor obtains an artificial supply of water, he has, besides, a right to all that he can procure by its sale. In cases where the proprietor furnishes seed, labour, or cattle to the cultivator, he receives, in addition to his tenth share, a portion of the farmer's profits. The government tax amounted at one time to one-tenth of the produce, but with the increasing expenses of the state other irregular taxes were imposed, till they were at last converted into an additional tenth; the less fertile lands being, however, subjected to a smaller impost. But other irregular and arbitrary imposts continued to be heaped upon the additional tenth by the bad faith of the government, and now form one of the cultivator's heaviest grievances. The other taxes are those on cattle, capitation taxes, transit and town duties, and various irregular impositions. Lands held in fief, or in lieu of military or other service, pay no tax to government; the assignee being entitled to three-tenths, which includes both the proprietor's rights and the government dues. When the assignment is given on the estate of another, the government dues alone are granted. Gardens near villages pay one-fifth of their produce in kind, whilst melon-grounds, tobacco, cotton, and such like fields, pay in money according to a valuation of their produce. Horses, asses, cows, sheep, and goats, are all taxed, at the rate of one real, or 1s. 4d. for each horse, four-fifths for asses and cows, one-third for sheep and goats, and one-sixth on the hive of bees. There is a capitation tax, which sometimes presses heavily upon Armenians, Jews, and Gabars, the ancient fire-worshippers. The rate was in some cases four reals, or 5s. 4d. for a family, and sometimes eight reals. Shops and bâzârs pay a duty of from two to twenty reals a year; and the tenant also pays in the proportion of from ten to fifty tumâns a year, the value of the tumân being 11s.[2] All merchandise is subject to a duty of 5 per cent. on entering the first Persian town, whether by land or sea, and to a variety of inland duties, which are levied at the different custom-houses, without any system, every governor endeavouring to extort all he can. Smuggling is very common. No estimate can be formed of the *saadrát*, or the irregular duties, which include every extraordinary expense of government, the expenses of all travellers and strangers, of members of the royal family, or government messengers, of transporting baggage, royal equipage, or presents, of repairing roads and bridges, of furnishing troops, and the like; for all which it is understood, though the practice is often different, that the village or province shall obtain credit on the annual settlement of their accounts; so that these heavy exactions, resembling those of the king's purveyors in ancient Europe for the maintenance of his court and retinue when they were travelling, fall without redress on the poor ryots. The Persian king's order

Persia.

is, in like manner, grievously abused to the oppression and vexation of his subjects. Presents, fines, and confiscations, form a considerable item of Persian revenue. At stated times, such as the new year, the courtiers are expected to accompany their respects to the king with a large present of money, which amounts in some cases to L.30,000, L.40,000, and even L.55,000. Every one in any degree dependent upon the court endeavours to make up a purse on this occasion; and in lieu of money, goods, such as shawls, horses, jewels, and merchandise, are brought. The produce of this new year impost is estimated at L.660,000. But there are various other lesser occasions for making presents, no suitor being expected to approach the throne empty-handed; so that about L.275,000 may be received in addition to the presents of the new year. The produce of the crown lands Fraser estimates, though, he admits, on uncertain data, at L.493,950.

According to Sheil (p. 388), the total expenditure from the revenue is as follows:—

General expenditure, including presents, building, post-office, &c.	L.184,536
Amalaját, or salaries at the capital	443,292
Total military expenses	672,520
Provincial expenses	160,782
	L.1,461,130

Army.

The Persian army at present comprises 6000 artillery, about one-half of whom are natives of Azarbíján. The men are active, efficient soldiers, and carry their guns over any ground. There is one marked peculiarity in this arm of the service. The artillerymen are all mounted, and there are more than thirty with each gun; the guns in Persia being to defend the infantry, rather than, as with us, the infantry to defend the guns. For the foundation of an ordnance department on a modern footing, Persia is indebted to England. A foundry under Englishmen was first established at Tabríz, as well as a powder manufactory outside the town. These have since been transferred to Tehrân. The regular infantry is rated at 100,000 men, but does not actually exceed 70,000. Of these, more than a third come from Azarbíján. Internal discipline is said by Sheil to have no existence, and knowledge of evolution to be limited to movement from column into line, and *vice versâ*, and to the clumsy formation of squares.[1] In the recent engagements, however, with the British forces, the Persian infantry did not appear to be so deficient in these points. The arms of the infantry are flint muskets, and bayonets, many of them out of order. The men wear blue linen jackets, with white cotton trousers and leather buskins; and in cold weather they often put on their own clothes under the jackets and trousers which are supplied by the state. Turks wear the lambskin cap, and Leks felt caps. Instead of knapsacks, thirty asses are allowed to each company for the carriage of the men's kit. The infantry is divided into regiments, each of which, called a *fauj*,[2] consists of 1000 men, of whom 800 are *sarbáz* or privates, 41 bandsmen, and 159 officers. The *fauj*, again, is divided into 10 *dastah* or companies, and in each there are 1 sultán, or captain; 2 *náibs*, or lieutenants; 2 *begzádahs*, who ride in the rear; 4 *vakíls*, or serjeants; and 4 *sarjaukas*, or corporals. The regiment is commanded by a *sarhang*, or lieutenant-colonel, who gets 500 tumâns (L.275) a year; and 2 *yávars*, or majors; and over two regiments is a *sartíp*, or colonel, with 1000 tumâns a year. The *yávar* receives from 150 to 250 tumâns a year; *sultín*, 60 tumâns; the *náib*, from 30 to 40; the *begzádah*, 20; the *vakíl*, from 10 to 12; and the *sarjauka*, 8 tumâns annually. The private receives 7 tumâns a year, and has, besides, a *jírah*, or ration of 3¼ lb. of bread daily. Each regiment has, besides, a *mushrif*, or head accountant, who gets 50 tumâns (L.27, 10s.); and four clerks, whose pay is from 30 to 40 tumâns each. Each member of the band gets from 8 to 15 tumâns. The regular cavalry is limited to 500 men; according to Sheil, "an absurd, useless body." The Shah's bodyguard consists of 2500 irregular cavalry, well mounted and armed, and excellent horsemen. Their pay is 60 tumâns each yearly, with 1½ *mans* of bread, 4½ of barley, and 9 of straw for the horses, per diem. Over every 10 men is a *dehbáshí*, or decurion; and over 100, a *yuzbáshí*, or centurion, who gets 500 tumâns annually. Besides these, there are from 30,000 to 50,000 irregular horse, called *ghúlám-i-suwár*, to distinguish them from *ghulám-i-rikábí*, the bodyguard. Sheil considers them fully equal to the Cossacks. Six thousand of them come from Azarbíján. The pay of a private is from 10 to 15 tumâns, with half a *man*[3] of bread, 1½ of barley, and 3 of straw, daily. A *sultán*, or captain of 50, gets 50 tumâns; a *náib*, or lieutenant, 30; *vakils* and *sarjaukas*, 15 tumâns; and a *sarkardah*, or colonel of horse, 1000 tumâns per annum.

The regular Persian army owes its origin to the French, and dates from the mission of General Gardanne in 1808. The first levies were raised in Karmânshâh and Azarbíján. Shortly afterwards, Major Christie and Lieutenant Lindsay, of the Company's army, who accompanied Sir J. Malcolm's mission in 1808, undertook the charge of the new levies. Major Christie was killed in 1812, in the battle of Aslanduz against the Russians, in which he distinguished himself so much that the victors raised a monument to his memory. He was succeeded by Major Hart of the royal army, who, under Abbás Mírzá, brought the infantry of Azarbíján to great efficiency. Lieutenant Lindsay, afterwards Sir H. Lindsay Bethune, did even more for the artillery; and the remains of the vigour he infused may still be traced. After the last war between Russia and Persia, several officers and serjeants of the Indian army were sent to carry on the work. Among the most distinguished was Sir H. Rawlinson. They aided in placing Muhammad Shâh on the throne; but that prince became jealous of them; and finally, on his marching against Hírát, they were recalled. After them came some French officers, who entirely failed; and they in turn were succeeded by a party of Italian, Hungarian, and German refugees.

Religion.

The ancient religion of Persia was the worship of Hormazd, the Good Principle, or God. Fire, and especially the sun, being considered the fittest emblem of the deity, was the visible medium selected to receive adoration, but that this emblem was itself worshipped, is a vulgar error. This religion was subverted by the Arabs in A.D. 651, when that of Muhammad was propagated in Persia by the victorious Muslims. But the Persians are of the Shíah sect, who consider 'Alí, the nephew and son-in-law of Muhammad, as his lawful successor in the khalífat, to which he was appointed by the Prophet; and Abúbakr, 'Umr, and 'Uthmán, his actual successors, and reverenced as the khalífs by the Sunnís as nothing better than usurpers. It was this disputed succession which gave rise to these two hostile sects of Muhammadans. The doctrines of the former,—namely, the Shi'ahs,—have been for more than three centuries warmly espoused by the Persians, who vowed eternal hatred and war against all who profess the Sunní creed. The religion of Muhammad, amongst its other evils, is hostile to all improvement. It enjoins the destruction of infidels as an act of piety; and hence the blind zeal and persecuting spirit which prevails in all Muhammadan states, and which breaks out into reproach, outrage, and often into extreme violence, against their Christian visitors. All knowledge is, according to this system, rejected, beyond what is found in the Kurân;

[3] Binning, vol. i., p. 177, note, reckons the *man* at 7 lb.

Persia.

and the debasing influence of polygamy on the morals and manners of both sexes is calculated completely to poison all the remaining sources of social happiness. The baneful consequences of this false system have been as deeply felt in Persia as in any of the surrounding states. The fanatical influence of the Muhammadan religion has of late years, however, been modified in Persia by the progress of a free-thinking and irreligious spirit, chiefly amongst the nobility, the merchants, and those who have resided much in foreign countries, and even amongst the priesthood, who frequently and openly, before their particular friends, deride the superstitious observances of the Muhammadan creed. The zeal of the early Muhammadans has also been cooled by many causes. The work of conquest, and the extinction or conversion of infidel nations by the sword, is at an end. The enthusiasm of the modern followers of the Prophet is no longer influenced by the practice of persecution; and the whole system has declined into a set of useless forms and ceremonies, which, mingling with all the common affairs of life, have degenerated into a customary routine, without any appearance of reverence, and being in reality a mere mockery of religion.

Literature, science, &c.

In a state of society such as that which prevails in Persia we can scarcely look for any great progress in literature, science, or the arts. With the Muhammadan religion was introduced all the Arabian learning of the seventh century. But the Persians have not improved this original stock; on the contrary, it has gone to waste in their hands; the light of science is nearly extinct, and their literature consists chiefly in poetry and tales. They delight in tales, fables, and apophthegms, which Sir John Malcolm considers as the consequence of their despotic government, where knowledge must be veiled in order to be useful, as the direct truth would wound a despot's ear. The merits of Persian poetry have been very differently estimated. Sir John Malcolm, admitting its extravagance and hyperbole, still praises its tenderness and beauty; and many passages breathe all the sweetness of pastoral poetry. Firdausí is their greatest epic poet, whose poem (the *Sháh-námah*) is a history of the ancient Persian kings. In it, according to Sir John Malcolm, "the most fastidious reader will meet with numerous passages of exquisite beauty. The narrative," he adds, "of this great work is generally very perspicuous; and some of the finest scenes in it are described with simplicity and elegance of diction." In the opinion of Persians, this poet excels in descriptions of the combats of heroes; but to those whose taste is offended with hyperbole, the tender parts of his work will have most beauty, as they are freest from this characteristic defect of eastern writers. Nizámí, who celebrates the exploits of Alexander the Great, is considered as ranking next to Firdausí; and the subject affords ample scope to his genius and powerful imagination. Amongst the didactic poets, Sir John Malcolm assigns the next rank to S'adí, who is a moralist as well as poet, his works abounding in lessons of prudence and morality, and exhibiting a rare union of fancy, learning, urbanity, and virtue. The Masnaví of Jalálu'd-Dín, the poems of Jámí, and the odes of Háfiz, are amongst the most popular effusions of the Persian muse; but the names of Rudikí and others are nearly of equal rank; and some modern writers also have attained to great eminence. "Many of these poems," says Sir John Malcolm, in his excellent History of Persia, "are remarkable for harmony of numbers and luxuriance of imagination, but they all abound with the most extravagant and hyperbolical passages; and the enraptured dreams of their visionary authors can only be esteemed beauties by men whose imaginations keep pace with that of the poet, whom they deem inspired, and whose most obscene lay is often considered by their enthusiastic admirers as the gleaming of a sublime knowledge, which is far beyond the comprehension of the profane and unenlightened. Many discussions have arisen regarding the real and mystical meaning of the writers of this class, and particularly of Háfiz, whose odes are chanted as songs, to excite the young and dissipated to pleasure, and recited as hymns, to remind the old and devout of the rapture of divine love." The Persian poets excel in songs and odes, which are tender and passionate. Satirical effusions are not so common; though the verses of Firdausí on Mahmud of Ghazni are remarkably bitter. There is a satirical poem, by an unknown author, on the passion of avarice, which is extremely humorous. The Persians are enthusiastic in their taste for poetry; and the meanest artisans can read or repeat the finest passages of their most admired writers. Sir John Malcolm mentions that his servants were familiar with Persian poetry; and when at Isfahán, he was surprised to hear a common tailor, who was repairing one of his tents, entertaining his companions with some of the finest mystical odes of Háfiz. Even the rude soldier will leave his tent to listen to songs of love or to a tale of war. The art of printing is unknown in Persia; and beautiful writing, which is carefully taught in the schools, is considered a high accomplishment, those who excel in it ranking with the literary class. They are employed in copying the works of authors; and a few lines written by a celebrated penman are often sold for a considerable sum. Almost all the tradesmen, and many of the mechanics in Persia, have received some education. Schools are established in every town and city, at which the poorest children are instructed, at fees sufficiently reasonable, in the rudiments of the Persian and Arabic languages. The pupil after he has learned the alphabet, reads, as a religious duty, the Kurán in Arabic; next some fables in Persian; and, lastly, is taught to write a legible hand, which completes his education. Unless amongst those who follow a studious life, and thus put in practice what they have learned, these lessons are in many cases forgotten. Yet this course of study, superficial as it appears, improves the habits, and introduces a refinement of manners amongst the scholars, which is unknown to their ruder countrymen. No proper encouragement, however, is given to schools; nor can it be expected that a grasping, despotic, and rapacious government, like that of Persia, should be any way anxious for the education of its subjects. The literary men are numerous. They pursue their studies till they are entitled to the name of Múllá, and to all the honours of a Persian college, though they are not classed with the priesthood. They follow various occupations. To the studious and literary classes a very high rank is assigned. An eminent historian, astronomer, or poet is highly honoured, and has a place of distinction assigned him in every company which he honours with his presence; and this as much for his social qualities as for his supposed talents as an author. The conversation of these persons, replete with anecdotes and information, amuses and instructs; and even the pretenders of this class, who are numerous, possess agreeable manners and a ready wit. A swarm of students is thus produced, who pass their useless lives in indolence and poverty. Isfahán in particular abounds with these literary mendicants; and from its colleges, and those of Shíráz, issue a crowd of vagrant poets, who lie in wait for men of rank and wealth, or for any stranger from whom they expect a reward.

In music and painting the Persians have made little progress. They have a gamut and notes, and a melody that is adapted to various strains; and they sing to the accompaniment of warlike instruments, of which they have a number. Their strains are often pleasing, but they are always monotonous. They are equally backward in the art of painting, in which they have advanced but little within the last three centuries. They use the most bril-

Persia.

liant colours; and in portrait-painting they usually succeed in taking likenesses; and in some of their lesser drawings, which are highly glazed, and painted on wood, they also display industry and taste. But they are entirely unacquainted with the rules of perspective or of just proportions. The despotic and unsettled government arrests all improvement; and in the fine arts the existing race have not advanced one step beyond their forefathers, as appears from the figures in the palaces at Isfahán, executed in the reign of Sháh 'Abbás, and equal to any of their modern productions.

Mathematics, astronomy, and geography.

In science the Persians have advanced no farther than in the arts. Their knowledge of mathematics or astronomy is very limited; and the latter science is chiefly studied for the sake of judicial astrology, in which the whole nation, from the king to the peasant, evince the greatest faith. Their notions of the forms and motions of the heavenly bodies, and the shape and surface of the earth, are borrowed from Ptolemy; and though some efforts have been made to instruct them in the Copernican system and Newton's demonstrations, prejudices are too firmly rooted to be dispelled, except by time. Of geography they do not understand the first principles; for, independently of their error regarding the figure of the earth, they know little of its surface, even of that which lies within their view; nor could their knowledge of surveying enable them to lay down any portion of it with exactness. There cannot be a stronger proof of the ignorance which prevails than the eagerness with which all classes seek the aid of astrology. Any one who can take an altitude with an astrolabe, or knows the names of the planets, with a few technical phrases, and understands the astrological almanacs, considers himself as quite adequate to offer his services to all who consult him; and nothing of consequence is transacted, especially by the great, without consulting stars. A new dress must be put on, or a journey must be commenced, at the lucky or unlucky moment.

As the science of astronomy is thus rendered subservient to astrology, so chemistry is followed for the sake of alchemy, a favourite pursuit of the learned, whose avarice is stimulated by the hope of discovering the philosopher's stone. The alchemists make their experiments in the profoundest secrecy, that they may themselves engross the whole benefits of the wonderful discovery which they expect to make; and whether they may be themselves deceived, certain it is they deceive others, and practise the most serious frauds on the credulous and the wealthy. Of medicine and surgery the Persians are thoroughly ignorant, and, when they are ill, become the prey of quacks, who rob them of their money, and often of their health. They are entirely ignorant of anatomy and the circulation of the blood. They have an arbitrary theory, by which they classify all diseases under four heads,—viz., hot, cold, moist, or dry; and the great principle on which they proceed is, that the remedy must be of an opposite quality to the disease; dry remedies being applied to an illness occasioned by moisture, and cooling medicines to hot diseases. To this practice they are so bigoted, that, with all their respect for European physicians, they dislike any prescriptions that contradict this paradox. Inoculation for the small-pox, though it is known, is seldom practised, though whole towns are often threatened with depopulation by the ravages of that dreadful disease. Mr Jukes, who accompanied Mr Fraser into Persia, was remarkably anxious to introduce the practice of vaccination; for several years his efforts were unremitted; but they were defeated, fully as much from the cruel indifference of the government to the good of their subjects, as from their prejudices. The practice of physic in Persia is mere quackery, for which all the knowledge necessary is that of the qualities and effects of a few simples; and hence a grave air, and a few lucky cures, often brought about by the temperate habits of the patient, complete the fame of a physician. The gains of the physician are, however, trifling. The priests and astrologers succeed better; their art is more suited to the taste of the inhabitants; and it is only in cities and towns that there are regular physicians. Those who dwell in tents are generally attended by an old man or woman, who rely more on superstitious charms than on medical remedies. One of these charms consists in laying a few pieces of bread covered with oil upon a rock, as an offering to a saint.

The Persians are remarkably ceremonious in their intercourse. They receive the visit of a superior by rising hastily and meeting him at the door of the apartment; of an equal, by rising and standing erect; of an inferior, by only making the motion of rising. The apartments are not so luxuriously furnished as in Turkey. The sofas and easy pillows of the latter country are not known in Persia, where the seat is on a carpet or mat, without any soft support on either side, or anything except the hands, or the accidental support of a wall, to relieve the galling posture of the legs. The fashion in presence of a superior is to sit upon your heels, as they are tucked up under your hams, after the manner of a camel. The length of time during which a Persian sits untired upon his heels is to an Englishman quite extraordinary. He will remain half a day, and sometimes he will even sleep, in this posture. They never think of changing their positions; and are as much surprised by the locomotive dispositions of the Europeans as we are by their habits of rest.

It is a singular trait of Asiatic manners that so great a proportion of the people still retain the vagrant habits of the pastoral life. For this purpose the wide wastes of Khurásán, varied with spots of fertility, are well adapted; and the pastoral tribes are accordingly found chiefly to border on this district, which has long been the debateable ground between several great monarchies, where their rival chiefs contended for victory in fierce and bloody wars; and on these occasions the wandering tribes are enlisted on one side or the other. Thus they are inured to blood and to pillage, and contract habits which have been strengthened by time, and have at last become interwoven with their whole pursuits and character. They often attack surrounding states, carry off the people, and sell them for slaves; and most of the wandering tribes of Turkamáns being Sunnís, who have sworn eternal hatred to the Persians, who are Shi'ahs, thus add religious hatred to all their other incentives to murder and pillage; so that their character is described as ferocious and blood-thirsty in the extreme. To the north of Khurásán there are various tribes of Turkamáns, who, occupying the country behind the Alburj and the steppe of Khárazm, pour from their deserts upon the surrounding and cultivated districts, plundering villages and caravans, with every circumstance of atrocious outrage. The old, the feeble, and the helpless are murdered on the spot; those who are fit for labour are carried into slavery; and whole districts of country are left desolate. From the east other tribes equally barbarous make inroads into Persia, and carry away their captives to the slave-markets of Khíva and Bukhára; and on the south and east are found the wild Bilúchís, who formerly murdered and plundered, but now, preferring their avarice to their cruelty, carry their prisoners to the slave merchants who frequent the great northern markets. The Afghán, also, though not naturally cruel, "assumes," says Fraser, "in this ominous neighbourhood a fierce character, and adds to robbery and plunder the crime of murder." By these dreadful inroads a considerable portion of the country to the north and east is laid waste; the terror of these tribes is spread far and wide; and their depredations have become more formidable in proportion to the corruption and increasing weakness of the Persian monarchy

Persia.

These tribes vary considerably in their physiognomy. The Goklán,[1] Yámút, and Takeh Turkamâns, who occupy the country behind the Alburj Mountains, bordering on the Caspian Sea, are tall, stout, and well made, and have all the Tátâr features,—namely, the scanty beard, the small eye drawn up at the corners, the high cheek-bones, and the small flat nose. Some, on the other hand, have handsome features, rather resembling those of the Asiatics than of the Europeans. The arms used by these tribes are chiefly the sword and the spear. They are dexterous in the use of the sword, which is curved in the Persian fashion, and very sharp. Several of the tribes use bows and arrows. They have very few fire-arms; only such as they have taken from travellers whom they have plundered.

Persia, the seat of learning, of wealth, and of improvement, whilst the greater part of the world had scarcely emerged from barbarism, might naturally be expected to abound in the precious relics of ancient art; and although many such memorials have perished amidst the ruthless devastations of war to which this and other Asiatic countries have been exposed, yet numerous monuments of taste still remain. Of these, the ruins of Persepolis belong to the earliest era of Persian history. It was in this city, which they took a delight in improving and embellishing, as the great metropolis of the East, that Cyrus and his immediate successors resided. It has for centuries presented only a scene of decay and ruin. The most remarkable remains in Persepolis, or, as it is called by the natives, *Istakhar*,[2] *Takht-i-Jamshíd* ("The Throne of Jamshíd"), are the Chihalminar, or forty "minarets or pillars," which are situated about 35 miles N.E. of Shíráz. Sir R. K. Porter recognised in these ruins, *en masse* as well as in detail, a strong resemblance to the architectural taste of Egypt; and he conjectures that some of the architectural ornaments may have been partly brought from that country by the Persian monarchs, as trophies of their victories. These magnificent remains appear to be part of the great castellated palace of Darius, which was set on fire by Alexander whilst he was under the influence of intemperance. They are placed as if in an amphitheatre, on a fine plain, inclosed by semicircular mountains. The terrace on which the ruins of this immense royal citadel or palace are is at the foot of a steep rock called the *Kúh-i-Rahmat*, or "Hill of Mercy," and overlooks the wide plain of Mervdasht. It is nearly 500 yards in length (according to Binning, vol. ii., p. 4), 312 in breadth, and from 10 to 20 high. Its form is irregular, and it faces to the west. "The strength and beauty of its construction," says Sir R. K. Porter, "cannot be exceeded. The steep faces of the rocky terrace are formed of dark-gray marble, cut into gigantic square blocks exquisitely polished, and, without the aid of mortar, fitted to each other with such closeness and precision, that when first completed, the perfected platform must have appeared as part of the solid mountain itself."[3] The exterior wall is built of black stones, much harder than marble, finely polished, and of such a prodigious size, that it is difficult to conceive how the workmen, without the aid of machinery, were able to move them. The only access to the summit of the platform is by a double flight of stairs of a very gentle ascent, on its western side. There are fifty-five steps, each step being 3½ inches in height, formed of blocks of marble so large that each of them is cut into ten or fourteen steps. The first flight of steps leads to an irregular landing-place of 37 feet by 44, from which springs a second double flight of forty-eight steps, which terminate on the ground level of the platform in a second landing-place, occupying 64 feet. On reaching the platform, the first objects that arrest the attention of the traveller are the lofty walls of an enormous portal, the interior faces of which are sculptured into the colossal forms of two immense quadrupeds resembling bulls, which are elevated on a pedestal 5 feet in height. The heads of the animals are entirely mutilated, so that Fraser says it is impossible to determine what species they were intended to represent. Round their necks collars of roses are executed with critical nicety; and over the chest back, and ribs, short curling hair, cut with that peculiar correctness and delicacy of chiselling which Sir R. K. Porter states to be a distinguishing characteristic of the ancient Persian sculpture. The wall that forms one side of this magnificent portal is 5 feet in breadth, 21 feet in length, and 30 feet in height. The one wall is distant from the other about 12 feet, and the space between is flagged with beautifully-polished slabs from the neighbouring rock.

Persia.

Eastward, at the distance of 24 feet in a direct line from the portal, once stood four magnificent columns, of which only two now remain. Their capitals are singularly beautiful. At the distance of 24 feet is a second portal, exactly resembling the former, only that it is 18 feet instead of 21 in length. Its inner sides are adorned with similar sculptures. But the animals here represented are of a gigantic size, and of a monstrous formation; the body and legs of a bull, with similar trappings to those already described, and enormous wings, the feathers of which are exquisitely cut. The heads of the animals, though greatly defaced, show the faces of men; the countenance has a cast of deep gravity, and a long and carefully-curled beard adds to the general majesty. The head is adorned with a diadem, on both sides of which horns are represented winding from the brow upwards towards the front of the crown; the whole being surmounted by a sort of coronet, formed of a range of leaves like the lotus, and bound with a fillet beautifully carved in roses.

Between the right of this portal and the magnificent terrace that supports the range of columns from which it takes its name, there is an area of 162 feet, in which is a cistern hewn out of the solid rock, in dimensions 18 feet by 16. The approach to the terrace is superb, consisting of a double staircase covered with the most beautiful decorations, and projecting considerably before the northern face of the terrace, which is 212 feet in length. At each extremity E. and W. rises another range of steps; and about the middle, projecting from it 18 feet, appear two smaller flights, rising from the same points. The extent of the whole range, including a landing-place of 20 feet, amounts to 86 feet. The ascent is extremely gradual, each flight consisting of some 30 low steps, 4 inches in height, 14 feet in breadth, and 16 in length. The whole front is covered with sculptures so thickly that the eye is bewildered amid the various groups. They consist chiefly of figures and emblematical devices. These sculptures are executed with a nicety of detail which gives them historical interest, as they mark with accuracy the costume of the time and the people, and the form and variety of the armour used at different periods.

But the most splendid division of the ruins is the magnificent colonnade, which occupies the terrace, and which, having survived the devastations of war and the wreck of empires, remains on the desolate plain a most impressive image of departed grandeur. The terrace upon which these pillars stand stretches N. and S. 350 feet, and from E. to W. 380 feet; the greater part of the intervening space being covered with broken capitals, shafts of pillars, and numerous fragments exquisitely sculptured. There were formerly four divisions of columns, namely, a central group of thirty-six pillars, with two rows of six each on

1 Fraser's *Narrative of a Journey into Khorassan*, pp. 256, 267.
2 Gulistán of S'adí, ch. iv., story 12. The word in its first sense means "pool," but it is now obsolete (Binning, vol. ii., p. ii., note).
3 *Travels in Persia, Georgia*, &c., vol. i., p. 583.

either side, as well as in front; in all seventy-two columns. Of the division in advance only one was standing in 1818 when Sir R. Porter visited the spot.[1] About 38 feet from the western edge of the terrace appears the second double range of columns, of which only five remained in 1818. The distance is 268 feet to the corresponding eastern rows, of which only four columns remained in the above year. At a distance of 60 feet from the eastern and western colonnades stood the central range of columns, to the number of thirty-six; but of these no more than five remained at the said period entire. The three exterior double rows of columns are of uniform architecture, and described by Sir R. K. Porter as being perfectly beautiful. "The total height of each column is 60 feet, the circumference of the shaft 16 feet, and its length from the capital to the top 44 feet. The shaft is finely fluted in fifty-two divisions: at its lower extremity begins a cincture and a torus; the former 2 inches, the latter 1 foot in depth. From thence devolves a pedestal, in form of the cup and leaves of a pendant lotus. It rests upon a plinth of 8 inches, and measures in circumference 24 feet 6 inches; the whole, from the cincture to the plinth, comprising a height of 5 feet 10 inches. The capitals which remain, though much injured, suffice to show that they were also surmounted with a double demi-bull. The heads of the bull forming the capitals take the directions of the faces of the respective fronts of the terrace; and I think there can be no doubt that the wide hollow between the necks received a beam, meant to support and connect an entablature, over which has been placed the roof." The dimensions of the central pillars are the same as those of the others, only that they are 55 feet in height, whilst the others are 60 feet. The capitals, however, which surmount them are of quite a different character, being of the same description with that in the great portal where the crowned and winged bull is so conspicuous an object. The two lower divisions of the capital (it being of a triad form) are evidently constructed of the hollowed lotus. The upper compartment has only two volutes. The middle compartment which is one division of lotus, appears to have had some extraneous body introduced into the opening between it and the lower compartment of the flower; and the angular and unfinished state of that side of the capital seems to testify the same. "Here then," says Sir R. K. Porter, "the connecting-line must have been whence the roof could spring."

The nearest building to the palace of the forty pillars occupies a space of 170 feet by 95, and it is approached by a double flight of stairs, which are almost in complete ruin; but from the fragments it appears to have been adorned with sculptures resembling the royal guards and other figures. The side to the E. is so choked up with ruins that no corresponding trace of stairs can be found. To the S. the whole face of the terrace which supports this building is occupied with another superb flight of steps, which terminates in a landing-place 48 feet by 10. Its front is divided by a tablet bearing an arrow-headed inscription, on each side of which are seen spearmen of a gigantic stature. There appear to have been also other apartments with lofty entrances, composed of four solid upright blocks of marble of a colour nearly black, within the portals of which are bas-relief figures of two guards sculptured on the sides of the walls, besides various other figures, one of a monarch clad in royal robes; whilst in other parts there are representations of single combats between a man and a lion, a griffin, or some other imaginary creature. In another division of the same building may be seen a variety of inscriptions, cuneiform, Kúfic, Arabic, and Persian. Still farther to the southward appear other elevations or terraces covered with vast masses of ruin, under which scarcely any traces of the original structure can be discovered; but here may be seen the remains of colonnades of elaborate sculpture. From the extremity of the eastern colonnade on the terrace of Chihal Minár is an expanse of 315 feet, the plain of which is interrupted by an immense pile of ruins, which has the appearance of having been heaped up for centuries, and which Sir R. K. Porter conjectures to cover a division of the palace answerable to that immediately to the S., and containing, as he supposes, the banqueting-chambers and other apartments; and this conjecture he supports by many special reasons and learned authorities. South of this is another terrace, on which he supposes that there stood those portions of the palace in which the monarch resided. Here are the bases and plinths of pillars, and fragments of beautiful sculpture, scattered about. The ponderous doorways and huge marble frames are yet in their places; they are of the finest workmanship, and are adorned with sculptures and figures such as those which have been already noticed, and of which our limits do not admit of a more detailed description. A considerable way N. from the columns stands a structure which is next in extent to the *Chihal Minár*, or the "Palace of the Forty Pillars." It is a perfect square of 210 feet on each side, and is entered by two doorways on each side, and by a grand portal 13 feet in width, whilst the others are only 7. These are all richly adorned with sculptures, representing scenes of state or of royal parade, or emblematical figures of lions and imaginary animals.

Among other remarkable antiquities of Persia, the tombs, supposed to be those of her ancient kings,—namely, Cyrus and his posterity,—have attracted the particular attention of travellers. These excavations or tombs are generally cut out of the solid rock. About 500 yards eastward from the Hall of Columns, in the face of the mountain, is found a niche 72 feet in breadth by 130 feet in height, divided into two compartments, and covered, as usual, with sculptures of nondescript animals, royal personages, and symbolical figures. Three quarters of a mile southward from Takht-i-Jamshíd, a tomb was discovered by Niebuhr, and visited by Morier, which seemed to have no entrance, from which he supposes that those receptacles for the dead were entered by subterranean passages. The sepulchres of Naksh-i-Rustam, which have been visited by various European travellers, are also very curious. There are four excavations cut out of the perpendicular cliff, at the height, according to Sir R. K. Porter, of 60 feet from the ground. The one he examined, and to which he was drawn up by ropes, consists of an excavation in the solid rock of about 14 feet, in the form of something like a Greek cross. The length of the cave, which forms the whole tomb, is 34 feet, and the height 9. It is adorned, like all the other ancient monuments, with a variety of richly-sculptured figures of men and animals, and emblematical devices. There are likewise numerous remains of antiquity in the plains of Murghâb, 49 miles N.N.E. of the ruins of Persepolis, and probably belonging to the same era, which are fully described by Morier and Porter. The most remarkable of these is the supposed tomb of Cyrus; an interesting monument, of which the latter writer gives an account with his usual accuracy. It is surrounded by other ruins, which bear traces of the same antiquity, as they contain numerous inscriptions in the ancient arrow-headed character.

The very curious sculptures on the mountain called Bí-Sitún have already been noticed. Some have thought the words mean "without pillars;" but it is probably a corrup-

[1] Pietro della Vallé was the first European who visited Istakhar. This was in 1621, and 25 pillars were then standing. In 1809 Morier found but 16.

Persia.

tion of a more ancient designation. Just over the fountain-head of a beautifully clear stream, which bursts from the mountain about 50 yards from this rocky platform, are seen the remains of an immense piece of sculpture, so greatly defaced that no continued outline can now be made out; but by close examination the rude forms of several colossal figures may be traced. The principal cause of the mutilation seems to be, that additions have been made to the original. In one place a Greek inscription has been introduced, and has, in its turn, been erased to make way for one in Arabic. These rude sculptures are generally supposed to be of high antiquity, some referring them to the age of Semiramis. Above these appears an interesting piece of sculpture, containing fourteen figures, one of a king trampling on a prostrate body, probably of some of his captives. He has a diadem and all the other badges of sovereignty; and a row of nine persons, having their hands bound behind them, and being themselves bound together by a cord round their necks, are seen approaching him in a suppliant posture, and with a dejected expression. Sir R. K. Porter supposes that these ten persons, including the one under the feet of the monarch, represent the ten tribes which were carried into captivity; and the design of the sculpture, which is executed in a style not inferior to any at Persepolis, is to commemorate the final conquest of Israel by Salmanaser, King of Assyria and the Medes. Above the head of each individual is a compartment with an inscription in the arrow-headed writing, full translations of which will be found in Rawlinson's *Herodotus*, vol. ii., p. 590.

There are other monuments of antiquity, as at Táki Bústán, already noticed, and at Sháhpúr, which belong to the era of the Sassanian kings, and which afford important and curious illustrations of these times. Fifteen miles north of Kázarún are the ruins of Sháhpúr, once the capital of Persia. At the entrance of the valley where it is situated stands an insulated hill, which exhibits portions of its ancient walls and towers; and the precipitous cliffs are carved with sculptures. On the southern side of the river which waters the plains, a much-mutilated bas-relief is carved on the surface of the rock, consisting of two colossal equestrian figures. Their height appears to be about 15 feet. A tablet, divided into three compartments, contains the second sculpture. In the central compartment is an equestrian figure, with the usual badges of Sassanian sovereignty. A suppliant is on his knees before the horse's head, his hands extended, and his face expressive of entreaty; whilst another figure with Egyptian features stands, likewise in the attitude of a suppliant, to the right of this compartment. The right-hand section contains three figures in attitudes of supplication. A greater number of tablets are still to be seen on the opposite side of the river. They contain various figures and designs, one of which is an elaborate representation of the triumph of a Persian over a Roman army. Colossal horsemen are pictured on others, with the royal emblems of Persia. In the Sháhpúr valley is a mountain, which is crowned by a perpendicular precipice of limestone 700 feet in height. Here is a cavern of enormous extent, its communication intricate and endless, with every form and variety of stalactites diversifying the different chambers, some of which are wonderfully lofty and spacious, and, when entered by torch-light, present the most brilliant reflection of all sorts of fantastic shapes. The entrance to the cave is about 140 feet above the base of the precipice; and here, in a spacious archway 150 feet broad, and nearly 40 feet in height, within which is a sort of natural ante-chamber, stands the pedestal of a statue, which lies mutilated and prostrate, with the head downwards. Both have been cut out of the solid rock. The figure, which, when erect, must have been from 15 to 20 feet in height, represents some one of the Sassanian kings — Sháhpúr, as is supposed. There are various other Sassanian relics in the vicinity of Persepolis,—namely, the tombs of the kings, where the sculptures, by the natives called Naksh-i-Rustam, are to be found; also the sculptures named Naksh-i-Rajib. The sculptures of Naksh-i-Rustam are contained in six tablets cut on the perpendicular rock, and containing many bas-reliefs of the triumphs or victories of the Persian arms under the Sassanian kings, with figures of the sovereign in various attitudes, and of horsemen engaged in hostile collision. The sculptures at Naksh-i-Rajib consist of three tablets containing seven colossal and two diminutive figures. One of the sovereigns is on horseback in his greatest pomp; and underneath is a Greek inscription, which has been restored and translated by M. de Sacy. It runs thus:—"This is the resemblance of the servant of Ormazd, the divine Sháhpúr, king of kings, of Irán and An-Irán, of the race of the gods, son of the servant of Ormazd, the divine Artaxares, king of kings, of Irán and An-Irán, of the race of the gods, grandson of the divine Babek the king." The remaining tablet contains but a repetition of the two horsemen holding a ring. There are other ancient monuments in different parts of Persia, consisting of sculptured rocks and other remains resembling Druidical erections.

History.

The early history of Persia is lost in remote antiquity, and for authentic accounts, the uncertain gleanings of oral tradition, or the fictions of poets, have been substituted. The *Sháhnámah* of Firdausí, the Homer of Persia, a legendary history of the Persian kings, composed of such materials, comprises all the information possessed by the Asiatic writers prior to the Muhammadan conquest. From this poem, and similar authorities, Sir J. Malcolm has compiled the early annals of Persia, and to it we refer our readers for some account of that dim era.

It will be sufficient here to mention that, according to the *Dábistán*, there were four dynasties before Kaiúmars, whom the Muhammadan histories, such as the *Zínatu-t-tawárikh* declare to have been the grandson of Noah, or Noah himself. These four dynasties, viz.,—1. That of Máhábád; 2. The Jaianian; 3. That of Sháh Kalív; and 4. That of Yessán,—are purely fabulous. The dynasty founded by Kaiúmars is called the Píshdádyan, and must be regarded as legendary and pre-historic, though doubtless there is a basis of truth in what is said regarding it in the *Sháhnámah*, of which it forms the sole subject. The kings were—1. Kaiúmars; 2. Húsbang, the discoverer of fire, and inventor of useful arts; 3. Tahmúras, the legendary founder of Babylon, Nineveh, and Isfahán; 4. Jamshíd, the founder of Istakhar or Persepolis, and inventor of wine; 5. Zahhák, the Syrian or Arabian, whom some take to be Nimrod; 6. Farídún; 7. Minúchihr; 8. Nauzar; 9. Afrásiáb; 10. Zú; 11. Karshasp; 12. Afrásiáb II., who was defeated by Rustam, and the victor placed Kai Kubád, a descendant of Minúchihr, on the throne, and with this prince commenced the Kaianian, or second dynasty, the monarchs belonging to which bore the following names:—1. Kai Kubád; 2. Kai Káús; 3. Kai Khusrau; 4. Luhrásp; 5. Gashtásp, in whose reign Zartasht or Zoroaster introduced the fire-worship; 6. Bahman, or Ardashír Dirázdast; 7. Dárá I.; 8. Dárá II., or Darius Codomanus of the Greeks.

From the evidence of the cuneiform inscriptions, and other monuments,[1] the true history of the rise of the Persian power appears to be as follows:—At a very remote period, during the existence of a powerful Assyrian monarchy, there took place a great migration of the Arian nation westward from beyond the Indus towards Persia and Media. In 880 B.C., the migration being still incomplete, that part of the Arian nation which was subsequently called the Medes encountered a great Assyrian king named Shal-Manuhara, whose history is recorded in the cuneiform character on a black obelisk, and has been deciphered. From this period, a struggle continued between the Medes and Assyrians till B.C. 710, when Sargon, the third king of the Lower Assyrian empire, completely subdued the newly-arrived tribe, and planted a number of cities in their territory, some of which were filled with Israelites, whom Sargon had carried off from Samaria. The Medes, however, constantly endeavoured to assert their independence; and in B.C. 633 Cyaxares shook off the Assyrian yoke, and, having taken Nineveh in B.C. 625, laid the foundation of the Arian empire, which, sixty-

[1] Rawlinson's *Herodotus*, vol. i., p. 406.

Persia.

seven years afterwards, was fully established by Cyrus. It has been shown by Mr Grote, in his History of Greece, vol iii., pp 307, 308, that the account given us by Herodotus of Deioces is foreign to the oriental character, and savours far more of the Greek; and Colonel Rawlinson remarks that the very name of Deioces is a mere repetition of that of Astyages, the one being a corruption of *Dahák*, "biting," and the other *Aj-dahák*, "the biting snake."[1] Further, it does not seem [illegible] Cyaxares would have been so universally regarded as [illegible] of the Median empire, had he been preceded by Phraortes. On the whole, therefore, it seems reasonable to consider what is said of the two first-named kings as mere fiction, and to look upon Cyaxares as the first leader of the Arian hordes, who founded a kingdom after their migration westward from the Indus, and the same as the Kai Kubád of the Persian writers. Kai Káús, then, would be Darius the Mede of the book of Daniel, that is, Cyaxares, grandson of the first Cyaxares, and son of Astyages by Ariene, the daughter of Alyattis, King of Lydia; and Kai Khusrau is Cyrus. Luhurasp, who is called in the inscriptions Kabaijiya, and Gashtásp, or Kishtásp, must be regarded as the same as Cambyses and Darius Hystaspes, and the Pseudo-Smerdis is called in the Bisitún inscriptions Gaumáta Gomates. It is very remarkable that there is no mention of Xerxes, or of his famous expedition to Greece, to be found in the Persian writers or the legends of that country. Instead of Xerxes, a Queen Homai is mentioned as having reigned thirty years in succession to Bahman or Ardishir Dirázdast, the Artaxerxes Longimanus of the Greeks. A further examination of the inscriptions is required to unravel these difficulties, and also to reconcile the Persian account of Alexander the Great with that which has been adopted from the Greek writers. According to the former, Alexander was the elder brother of Dárá or Darius II., being the son of Dárá I. by the daughter of Philip of Macedon. In the meantime, enough has been discovered to show that there is much fiction in the accounts of this Persian dynasty furnished by the Greeks. With these preliminary remarks, we proceed briefly to notice the chief circumstances mentioned by those writers.

Arbaces, according to Prideaux, who makes this prince the Tiglath-Pileser of Scripture, was the first sovereign of Media. He flourished B.C. 747, and conspired with Belesis, governor of Babylon, and other nobles, against Sardanapalus, with whose death terminated the Assyrian monarchy. Without attempting to reconcile this view with that which makes Deioces the first, or that which, regarding Deioces as a fabulous character, substitutes Cyaxares for him, we proceed to note the statements of the Greek historians. Cyrus, according to them, was the chief of a pastoral horde, who, quitting their own comparatively barren and unproductive country, subdued the territories of their wealthy and luxurious neighbours. He was the conqueror of Babylon, and on the ruins of that great kingdom founded that of Persia, which was gradually extended by conquest from the Mediterranean to the Indus and the Oxus. Cyrus was succeeded, in the year 529 before Christ, by Cambyses, the Ahasuerus of the Scriptures, who gave himself up to sensuality and cruelty. Still he extended his empire, having reduced Egypt to the state of a colony, and also conquered a great part of Northern Africa. Pseudo-Smerdis, feigning himself to be the brother of Cambyses, who had been murdered, was by a faction of the Magi raised to the throne B.C. 522. Otanes, a Persian nobleman, finding out the deceit, conspired with six other chiefs, who agreed to assassinate him, which they effected, after he had reigned eight months. Along with him they put to death a number of the Magi; and having decided on a monarchical form of government, they resolved to assemble next morning at sunrise without the city, on horseback; and it was agreed that he whose horse should neigh first should be chosen king. The well-known trick of Æbares, the groom of Darius Hystaspes, secured the throne to his master, 521. He brought his master's horse the evening before, with a mare, to the appointed spot; and the horse, as soon as he arrived next morning, recollecting the mare, neighed, and he was immediately saluted king. The Greek character and fabrication of these tales is self-evident. Darius Hystaspes reigned over Persia thirty-six years, and was distinguished as a legislator as well as a conqueror. He divided the country into nineteen satrapies or provinces, each liable for the payment of a fixed tribute. Over these provinces satraps were sent to preside, with the delegated authority of the king. Their duties were, to collect the revenue, to improve agriculture, and to perform all the royal commands. They were afterwards invested with military commands; and securities were devised against their usurpation of independent authority. An establishment of couriers was at the same time instituted, for expediting orders through every part of the empire. A regular and efficient military force was also organized by this monarch, and maintained at the expense of the different provinces. In process of time, Grecian mercenaries were taken into pay; and, when the country was engaged in war, the army was recruited from the people.

Persia.

The reign of Darius was distinguished by several important warlike expeditions. Crossing the Thracian Bosphorus, he invaded Europe with 700,000 troops. But the Scythian tribes between the Danube and the Don successfully resisted his attack, and forced him to retreat with loss. He then overran the territories of Thrace and Macedonia, and left Megabyzus to complete the subjection of those provinces. He next invaded the countries to the east of Persia with a powerful army, and conquered some of the countries bordering on the Indus, which he formed into a twentieth satrapy, under the name of India; and his vast armies were also sent to overwhelm the rising communities of Greece. But his troops, though they far outnumbered their enemies, were completely overthrown on the plains of Marathon by the forces of the Greeks. Amidst these disasters the reign of this monarch terminated; and he was succeeded by his son Xerxes B.C. 486.

Xerxes carried on a successful war against the Egyptians, whom he gave over to the vengeance of his brother Achæmenes; and he resolved to avenge himself on the Greeks. With this view, he fitted out a mighty armament, in which he embarked an army amounting to 3,000,000 of troops, or, with all the camp followers, to above 5,000,000;[2] and with this vast force he resolved to annihilate the independence and liberties of Greece at a single blow. But he was met by the devoted bands of Grecian patriots, and experienced a severe check at the celebrated pass of Thermopylæ, which was defended by 300 Spartans against his whole army, and which he only carried by an immense sacrifice of men; and his fleet and army were finally overthrown at Salamis, Platæa, and Mycale, he himself escaping from the scene of action in a miserable fishing-boat. He was assassinated, after a reign of twenty-one years.

He was succeeded, in 464, by his grandson Artaxerxes Longimanus, the Ardishír Dirázdast, or Longhands of the Persian historians. He is celebrated for the internal regulation of his empire, and for the intelligence which he acquired relative to all the concerns of the kingdom, by means of the agents whom he employed. He is represented by some as the Ahasuerus of the Scriptures, because he is said to have treated the Jews with lenity and kindness, and to have married one of that nation. The two succeeding sovereigns were Xerxes II. and Darius II. whose reigns were short. The latter was succeeded in 605 by Artaxerxes Mnemon, his eldest son, who had to contend for the crown with his younger brother Cyrus. It was in his reign that the famous retreat of the Ten Thousand took place under Xenophon, who has given a narrative of the expedition. His reign, which continued twenty years, was a scene of intrigue, in which favourites bore the chief sway, and during which those symptoms of decay became visible which terminated at last in the overthrow of the kingdom. He was succeeded by Darius or Dárá I., who reigned only twelve years. In the year 336 B.C., Darius Codomanus, or Dárá II. of the Persian historians, assumed the sceptre. It was in his reign that Alexander of Macedonia, having subdued the different principalities of Greece, and consolidated their power into one, invaded Persia. He crossed the Hellespont in the year 334 B.C., with a well-disciplined and veteran force of 35,000 men, and encountered and defeated the Persian host on the banks of the Granicus. The hasty levies of Persia were again routed in the fatal battle of Issus, in which 100,000 were slain; and the family of Darius fell into the victor's hands. The battle of Arbela, which succeeded, completed the triumph of Alexander. The Persian armies were routed and dispersed, and the unfortunate Darius, flying from the field of battle, was seized by his nobles, at the head of whom was Bessus, who bound him in golden chains, and were carrying him to Bactriana in a car covered with skins; but being overtaken by the conqueror, they stabbed their victim to the heart, and left him in the chariot weltering in his blood. With Darius terminated the dynasty of Cyrus, which had subsisted 206 years, according to the Greek writers.

After the death of Alexander, Asia continued for a long period a scene of war and commotion, owing to the contests which arose amongst his successors for the dominion of the country. But about the year 307 B.C. Seleucus Nicator by his success had acquired the dominion of all the countries which lie between the Euphrates, the Indus, and the Oxus, and had even carried his victorious arms to the Ganges, and established a friendly alliance with Sandrocottus, or Chandra Gupta, King of Pataliputra, who reigned on the Ganges, near Alláhábád. In B.C. 279 Seleucus was succeeded by Antiochus Soter, who again, in 261, was succeeded by Antiochus

[1] Rawlinson's *Herodotus*, vol. i., p. 408, note.

[2] The absurdity of these numbers needs no comment.

Persia.

Theus. In the eleventh year of his reign, or, according to Thomas,[1] in 255, the Parthians revolted under Arsaces, who founded the third Persian dynasty, the Arsacidæ or Ashkanians,—Ashk being the name given to Arsaces by the Persians. Arsaces, enraged at an affront offered to Tiridates his brother, put the governor of Parthia, Agathocles, to death, and declared himself independent.

The following, as given by Thomas, vol. ii, p. 299, is the list of the Ashkanian kings, of whose authentic history little is known :—

	B.C.		A.D.
1. Ashk, or Arsaces I.	255	19. Artabanus III	13
2. Tiridates I., or Ashk II.	253	Tiridates III	
3. Artabanus I., or Shahpúr.	216	Cinnamus	
4. Phraapatius	196	Artabanus III.	
5 Phrahates I.	181	20. Bardanes	42
6 Mithradates I.	173	21. Gotarzes, or Bahram Gudarz	45
7. Phrahates II.	136	22. Meherdates	50
8. Artabanus II.	126	23. Vonones II.	51
9. Mithradates II.	123	24. Vologeses I., or Volas	51
10. Mnaskires	80	25. Artabanus IV., or Hormúz	62
11. Sinatroces	77	26. Pacorus or Firúz	77
12. Phrahates III.	70	27. Chosroes or Khusrau	108
13. Mithradates III	60	28. Parthamaspates	115
14. Orodes I.	54	29. Chosroes restored	116
15. Phrahates IV.	37	30. Vologeses II., or Volas	121
	A.D.	31 Vologeses III., or Volasin	148
16. Phrahataces	4	32. Vologeses IV.	192
17. Orodes II.	5	33. Vologeses V.	209
18. Vonones I.	5	ArtabanusV., or Arduan	
34. Artaxerxes, King of Persia, first of the Sassanidæ			235

The alternative appellations are those given by the Persian historians, who, it will be seen, omit the majority of these princes altogether. They are also silent as to the wars between this dynasty and the Romans. We learn, however, from the historians of the West that Pacorus, the 26th king, sent an embassy to Sylla in A.D. 90; and that in A.D. 53, Crassus, having passed the Euphrates a second time to carry on a war he had commenced against the Parthians, was defeated and slain, with 20,000 of his men, and 10,000 were made prisoners. Next year Cassius, his quæstor, who had carried off the remains of the army, repelled from Syria an invading Parthian army; and in 51, on their returning and besieging Antioch, he defeated them again with great slaughter. In the years 41 and 40, however, they returned and conquered all Syria, and took Jerusalem, slew Phasael, made Hyrcanus prisoner, and settled Antigonus on the throne of Judea. In 39 Ventidius defeated the Parthians in a great battle, and drove them out of Syria; and in 36, Antony having invaded Parthia, was repulsed with the loss of the larger portion of his army. In 20 B.C. the Parthian king sent an embassy to Augustus to seek his friendship, and restored the standards taken from Crassus and Antony, and all the surviving prisoners.

In 165 A.D. the generals of the Emperor Marcus took Seleucia, which had become the Parthian capital, and put 300,000 of the inhabitants to death. They at the same time pillaged and destroyed Ctesiphon; but this latter city, in 198, had become so populous and strong, that it maintained an obstinate defence against the Emperor Severus, and, when stormed, supplied him with 100,000 captives. Even after this, Ctesiphon recovered, and became the winter residence of the Parthian monarchs. About the year 217, the Emperor Macrinus purchased a disgraceful peace for Parthia by the payment of a sum equivalent to three millions of our money. This is all that is known of a period which is justly declared by D'Herbelot to be the most obscure in Persian history.

The Sassanian dynasty of kings forms a new era in the history of Persia. These monarchs were engaged in long and bloody wars with the Roman emperors; and hence we are enabled to correct the imperfect records of the East by the authentic narrative of the Roman historians. The first of these, Artaxerxes, or Ardishír, as he is called by the Persian historians, began his reign A.D. 226, and, having pacified the province of Fárs, made himself master of 'Irák. Having defeated and slain Aravan or Artabanus, who ruled over the mountainous country about Hamadán and Karmánsháh, he was hailed in the field with the title of *Sháhansháh*, or "King of Kings,"—a name which has ever since been assumed by the sovereigns of Persia. In the course of his reign he extended and consolidated his newly-acquired dominions, and waged, with various success, a war with the Roman emperor Alexander. He laboured to restore the religion of Zoroaster, and the authority of the Magi, which he enforced by the most sanguinary decrees. He was succeeded by his son Sháhpúr or Sapor, A.D. 238, who carried on a successful war against the Romans, whose emperor, Valerian, in an attempt to relieve Edessa, was defeated and taken prisoner. Sháhpúr gained many victories over the Roman armies; but towards the latter part of his reign he suffered reverses. His army was attacked by Odenathus, prince of Palmyra; and his country was afterwards invaded by Aurelian, the warlike Emperor of Rome Hurmuzd his son, the Hormisdas of Greek authors, reigned only one year, and was succeeded by Bahrám or Varanes I in 271, who evinced his zeal for the ancient religion of Persia by the execution of Mani, founder of the sect of Manicheans. He reigned three years and three months, and was succeeded by Bahrám or Varanes II., a weak prince He engaged in a war with the Emperor Carus, who conquered Mesopotamia, carried his arms across the Tigris, and made himself master of Ctesiphon. Bahrám or Varanes III. reigned only three months. His brother Nársi (the Narses of the Greeks) reigned nine years, and abdicated in favour of his son Hurmuzd or Hormisdas II. He subdued Armenia, and signally defeated the Emperor Galerius on the same fatal field on which Crassus had been slain. The Romans invaded Persia next year, and defeated Narses, who fled, leaving his tents and family in possession of the conquerors. An inglorious peace followed, by which Mesopotamia and five districts to the eastward of the Tigris were ceded to the Romans No events of any consequence occurred during the succeeding reign of Hurmuzd II. He was succeeded in 308 by Sháhpúr or Sapor II., who was crowned king from his birth, and during a reign of seventy-one years maintained the integrity of his kingdom. His first operations were directed against the Arab tribes, on whom he took a severe vengeance for having invaded his territories. He was involved in bloody wars with the Romans, in the course of which he experienced serious reverses. Constantine advanced into Persia with a formidable army, and was joined by the Arab forces. A dreadful conflict took place, in which the Persian army was routed with great slaughter; and the king himself narrowly escaped, with a few followers, from the fatal field. But having recruited his army, he again took the field; and in a night attack he recovered some of the advantages which he had lost. He was also successful in repelling the invasion of Julian, who was killed by an arrow; and his successor Jovian was fain to purchase a peace by the loss of all the provinces east of the Tigris, which had been ceded in the former reign. He was succeeded by Ardishír or Artaxerxes II, who was deposed by Sháhpúr, the son of the late monarch, after a reign of four years. He reigned only five years, when he was killed by the fall of a tent, which was blown down by one of those whirlwinds which sometimes occur in Persia. Bahrám or Varanes IV., who succeeded, reigned eleven years, and was at length killed in 399 by an arrow, in endeavouring to quell a tumult in his army. The throne of Persia was next filled by Yezdijird, the Greek Isdegerde. He is very differently represented by the Persians and Greeks; by the former as cruel and abandoned to luxury, and by the latter as wise and virtuous. He was killed by a kick of his horse, after a reign of twenty years. Bahrám Gúr, or Varanes V., succeeded, and became celebrated for his munificence and generosity His dominions were invaded, and partly overrun, by the Tátárs, who, being flushed with their conquest, gave themselves over to a false security, and were one night surprised and defeated with great slaughter by Bahrám. The only fruit which he sought from this victory was peace with all his neighbours, after which he returned to his capital. He was engaged in wars with the Romans under Theodosius, in which neither party had any cause to boast. His ruling passion was the chase, and he was fond of hunting the wild ass; and it was in pursuit of one of these animals that he lost his life in a deep pool near Ausepas, about three marches from Shíráz, on the road to Isfahán.[2] According to the *Sháhnámah*, however, and other authorities, he died a natural death. He was succeeded in 440 by his son Yezdijird II., who followed his father's footsteps, and during his reign of eighteen years was only once engaged in war with the Romans. The succession to the throne was now disputed between Hurmuzd or Hormisdas III., the younger son of Yezdijird, who was appointed heir by his father, and Fírúz or Perose the Elder, who, being supported by an army of Tátárs, to whose king he fled for support, and by the chief nobles, succeeded in wresting the sceptre from his brother's hand, and in putting him to death, after reigning a year. He lost his life in an expedition which he undertook against the Tátár prince, by whom he had been treated with so much generosity. Ballas or Palash, the son of Fírúz, now ascended the throne (485), and was succeeded by Kubád or Cavades, who, though he was dethroned by his discontented subjects, re-conquered his lost dignity. He carried on a successful war with Anastasius the Roman emperor, and died, after a long and troublous reign, in 531.

His son and successor Khusrau Núshírván, or Chosroes, is celebrated by the Persian historians as a model of justice, generosity, and sound policy. He is said to have been the fruit of a casual amour of Kubád, who, flying from his brother Fírúz, then established on the throne, halted for a night with a beautiful girl at

Naishápúr. Four years afterwards, on his return to that city, his fair mistress presented him with a boy, who was one day to reign so gloriously on the Persian throne. His first care after his accession to the sovereignty was to extirpate the pernicious sect of Mazdak, encouraged by his father, one of whose leading tenets was a community of property and of women. The founder of the sect and many of his followers were put to death; and the women and property which they had appropriated were restored to those to whom they belonged. He was indefatigable in promoting the prosperity of his dominions, in building and repairing bridges, in restoring and re-peopling decayed towns and villages, in founding schools and colleges, and in giving every degree of encouragement to learned men and even to the Greek philosophers who resorted to his court. His empire was divided into four great governments—namely, 1st, Khurásán, Sístán, and Karmán; 2d, The lands dependent on the cities of Isfahán and Kum, the provinces of Gilán, Azirbiján, and Armenia; 3d, The provinces of Fárs and Ahwáz, and 4th, 'Irák, which extended to the frontier of the Roman empire. A well-digested system of provincial government was introduced into those provinces, and every check adopted that could prevent the abuse of power. He imposed a fixed and moderate land-tax all over his dominions, and a capitation-tax on the Jews and Christians; and the strictest regulations were adopted for preserving the discipline of his army. The reign of Núshírván was illustrated as well by his conquests abroad as by his wise policy at home. He compelled Justinian to conclude a disgraceful peace at the price of 30,000 pieces of gold; and the reduction of Syria, the capture of Antioch, and the advance of the Persian armies to the shores of the Mediterranean, attest his triumphant reign. Though he was checked in his career of conquest towards the west, yet his sway was finally extended over the countries beyond the Oxus, some provinces of India, and the finest districts of Arabia. He reached the advanced age of more than eighty years.

Hurmuzd or Hormisdas IV., the son of Núshírván, ascended the throne in 579. His administration was wise and prosperous for a time, whilst he acted under the advice of his preceptor; but on the death of the latter, he fell into every excess, and, after a short and disastrous reign, was dethroned and put to death by one of his generals, Bahrám Chúbín, who usurped the supreme authority. But Khusrau Parvíz, or Chosroes II., the son of the late king, flying to the Roman emperor Maurice, his adopted father, was, by his assistance, re-instated in the throne (591), and Bahrám was forced to seek refuge amongst the Tátárs, whose armies he had formerly defeated, and amongst whom he died. The new monarch showed his gratitude to the Roman emperor by scrupulously fulfilling all the engagements he had contracted with him. He surrendered Dárá and several other strong places on the frontier, and, besides, sent him costly presents. But no sooner did he hear of the death of Maurice, than he invaded the Roman territories with a large army; pillaged and destroyed Dárá, Mardin, Edessa, and Amida; laid waste Syria; took the holy city of Jerusalem; and set on fire the magnificent churches of St Helena and Constantine. The true cross, which had been inclosed in a golden case, and buried deep in the earth, was discovered, and borne in triumph to Persia; and a crowd of captive priests and bishops swelled the train of the conqueror. Egypt was added to his other conquests; his troops entered Alexandria in triumph; and, after carrying his victorious arms westward to Carthage and Tripoli, and finally extirpating the Greek colonies of Cyrene, he returned in triumph through the sands of the Libyan desert. In the same campaign another army advanced from the Euphrates to the Thracian Bosphorus; and, after taking Chalcedon, his victorious troops remained encamped for twelve years in the vicinity of Constantinople. But, whilst his generals and his armies were thus gaining laurels in the field, Khusrau was indulging at home in the most unheard-of luxury. Every season a splendid palace was raised; and his thrones were made of the most exquisite materials, one being formed to represent the twelve signs of the zodiac and the hours of the day. His treasures; his wives, amounting to 12,000, besides the incomparable Shírín, or Irene the daughter of Maurice; his horses, amounting to 50,000; his Arabian charger of surpassing fleetness; and his musician Barbud,—furnish inexhaustible topics for the pen of the historian, and for the hyperbolical praises of his countrymen. But his reign, hitherto glorious, was, towards its termination, closed with misfortunes. Herodius, the Roman emperor, alike remarkable for luxury and indulgence in the palace, and for valour and military skill in the field, was roused to a sense of the public danger by the victories of Khusrau, and with a powerful army suddenly invaded Persia. In the course of six years he succeeded in stripping the Persian king of all his foreign conquests; he defeated his armies in every encounter; marched without opposition into the heart of his country; destroyed his splendid palaces, and plundered his hoarded treasures. His subjects, headed by his own son, at last rebelled against him, and put him to death, after a reign of thirty-eight years. Persia, after the death of this prince until the accession of Yezdijird III. in 632, was a scene of confusion and misery, from the combined evils of famine, the contentions of the nobles, a succession of weak sovereigns, or rather, as Sir J. Malcolm terms them, pageants of power, and from the threatened attack of the Arabian tribes, who, under the standard of the Muhammadan faith, had now become very formidable to all surrounding states. In their first attacks on the Persians, the Muslim armies were repulsed, and their leader Abú Obaid was slain. The Arabs, reinforced, were again defeated by Mehrán the Persian general. But in another action the Persians were defeated, and their general slain. Yezdijird, who was now elevated to the throne, was the last hope of the sinking state. An ambassador was sent to him from the Arabian tribes, proffering peace on condition that he should accept of their religion, and pay the taxes which all believers are bound to pay. These terms were rejected with disdain. Great armies were now assembled on both sides; they met on the plains of Náhávand, A.D. 641, where the Muhammadans gained a remarkable victory that for ever decided the fate of Persia. The Persians brought 150,000 men into the field,[1] of whom 30,000 perished on the field, and many more were drowned in a deep trench which surrounded the camp. Persia, from this date, fell under the dominion of the Arabian khalifs. Yezdijird, the last monarch of the Sassanian line, fled from the field of battle to Sístán, to Khurásán, and lastly to Marv, from which being also forced to fly, he concealed himself in a mill eight miles distant. But the miller, tempted by his rich robes and armour, murdered him whilst he slept, and thus ended, A.D. 651, the dynasty of the Sassanides, and the Magian religion, which had existed in Persia for 1200 years.

After the flight of Yezdijird, the armies of Persia, scattered and discouraged, were able to oppose only a feeble resistance to the hardy children of the desert, skilfully commanded, and, besides, inflamed by a fanatic enthusiasm: and in a short time, accordingly, they overran and laid waste the whole country with a bigoted fury that had no parallel, sparing neither sex nor age, and subverting in one common ruin the laws, manners, and most sacred institutions of the country. Many were contented to purchase life by embracing the new faith; and others fled to the mountains and fastnesses of the country, or to a distant land. "The progress of the conquerors," says Sir John Malcolm, "was rapid and wonderful; colonies from the burning deserts of Arabia were extended over the cold countries of Khorassan and Balkh; and they flourished on the soil to which they were transplanted."[2] The conquest of the country being completed, it was divided into different provinces, over which lieutenants were appointed; and it was thus held for more than two centuries under the dominion of the khalifs. Towards the year 868 A.D. the dominion of the khalifs began to totter to its fall. In that year an adventurer expelled the governor of the khalifs from Persia. He was Yákúb-bin-Lais (or *Suffár*, whence this dynasty was called the Suffarides), the son of a pewterer of the name of Lais, in Sístán. He worked, when young, at his father's trade; but he was prodigal of his money; and, tempted by his necessities, he became the leader of a desperate band, which gradually increased with the success of his enterprises. He soon attained power and consideration; and his aid was solicited by Sálah-ibn-i-Násir, the ruler of Sístán, against his fellow-ruler of Khurásán. He was afterwards raised to be commander of Sálah's army; and the first use he made of his power was to seize on the chief who had conferred it on him, and to send him to Baghdád,—a service for which he claimed and received the government of his native province, as the servant and lieutenant of the Faithful. He afterwards took the important fortress of Hírát, reduced the province of Karmán, marched thence to Shíráz, and finally made himself master of the greater part of Persia. The khalíf, secretly dreading his power, sent him a formal investiture of certain territories as governor, which he rejected with disdain. In A.D. 873 the Khalíf Muhammad declared Yákúb a rebel, upon which that ambitious chief marched against Baghdád, but was obliged to retire with the loss of the greater part of his army. In 877 he marched again to the attack, but was overtaken by disease, and died, leaving almost the whole kingdom of Persia to his brother 'Amrú, who reigned twenty-three years, but was defeated and taken prisoner by Isma'íl-bin-Ahmad, a Tátár chief with whom he was at war, and, being sent to Baghdád, was there executed. With Amrú fell the fortunes of his family; and though two more princes maintained a precarious authority, the empire of Persia was divided between two families, Sámání and Dilamí. The power of the first extended over Khurásán, Sístán, Balkh, Transoxiana, including the cities of Bukhára and Samarkand. The Dilamí princes exercised sovereign power over the greater part of 'Irák, Fárs, Karmán, Khuzistán, and Láris-

tán. The following is the list of the Sámánides and Dilamites. Their names are as follows:—

Samanian or Samaní Dynasty.

	A.D.
1. Nasr-bin-Ahmad	874–5
2. Ism'aíl-bin-Ahmad	892
3. Ahmad-bin-Ism'aíl	907
4. Nasr-bin-Ahmad	914
5. Núh-bin-Nasr	943
6. A'bd-ul-Malik-bin-Núh	954
7. Al-Mansur-bin-Núh	961
8. Núh-bin-Al-Mansúr	976
9. Al-Mansúr-bin-Núh, deposed and blinded	997
10. A'bd-ul-Malik-bin-Núh	[illegible]99
11. Ism'aíl-bin-Nuh, killed	1005

Dilamites.

	A.D.
1. 'Ali [illegible]	[illegible]
2. Rukun'd-[illegible]	[illegible]
3. 'Izzu'd-daulah, who, after a short time is deposed by Azadu'd-daulah, who constructed the Band-amir, or famous dam near Persepolis	977
4. Samaniu'd-daulah	982
5. Majidu'd-daulah, taken prisoner by Mahmúd of Ghazni	1007
6. Malik Rahim, made prisoner by Togral Bey Seljuki	1055
7. The last of the race dies in the service of Alp Aslan.	1094

Of the Sámánian dynasty, Ism'aíl was the most celebrated. His grandfather was a Tátár chief named Samán, who claimed descent from Bahrám Chúbín, the Sassanian. He extended his conquests both eastward and westward, and died in 907, at the age of sixty. In the reign of Amir Núh, the fifth Sámánian king, Alptagín, his viceroy in Khurásán, purchased a Turkish slave named Sabuktigín, and, finding him to possess great qualities, gave him the highest offices, and at last bequeathed to him all his estate. Sabuktigín was thereupon chosen to succeed to the viceroyalty of Khurásán; and in A.D. 367 made war upon Hindústán with such success that Núh recognised him as an independent prince, and, as such, called him to his succour against the King of Turkistán. Sabuktigín died in A.D. 387, and left his son Mahmud to succeed him. This prince was the celebrated Mahmud of Ghazni, whose Indian wars are so celebrated. He died in 1208; and his successor Masa'úd was defeated by the Seljuk Turks; and in the next reign the House of Ghazni lost the whole of their Persian possessions. These Tátár tribes were numerous and powerful; they were a nation of shepherds, inured to fatigue, to long marches, and to every kind of hardy exercise, and trained from their infancy to the use of arms. Their numbers and discipline enabled them to overpower the civilized inhabitants of more fertile countries. Accordingly, in the year 1042, the Tatár tribes subdued Khurásán; and their sovereign, Togral Beg, chief of the tribe of Seljuk, assumed the state of a sovereign at Naishápúr. In the succeeding twenty years Togral overran all Persia, made himself master of Baghdád, and took prisoner the sovereign pontiff, the commander of the Faithful. He approached him, however, with every outward mark of reverence, and was constituted the temporal lieutenant of the eastern and western divisions of the empire. This alliance was further cemented by a marriage with the daughter of the khalif. But Togral Beg, who had by this time attained to his seventieth year, died a few months after the marriage. He was succeeded in 1068 by his nephew Alp-Arslan, the "Valiant Lion," who has been praised by all historians for his justice, valour, and generosity. He successfully defended his dominions against an invasion by the Romans, defeated their armies, and, having made their emperor prisoner, generously set him at liberty for a fair ransom. He was killed by a rebellious chieftain whom he had ordered to be put to death, but who, having shaken off his guards, assailed him on the throne with all the fury of despair. Alp-Arslan, an unerring archer, seized his bow, and commanded his guards to stand aloof: but for the first time his arrow missed its mark, and he fell under the assassin's stroke.

The celebrated Malik Sháh, his son, succeeded to the throne in 1072; and his reign rivalled, and even surpassed, in glory that of his father. Syria and Egypt were subdued by his victorious generals; Bukhára, Samarkand, and Khárazm yielded to his sway; and he received homage and tribute from the tribes beyond the Jaxartes, and from the distant country of Kashgár. Including the territories of all those princes whom he had conquered, and obliged to do him homage and to pay tribute, his dominion extended from the Mediterranean to the wall of China. The country was greatly improved during his reign; many colleges and mosques were built; and agriculture was promoted by the construction of canals and water-courses. Learning was also encouraged; and an assembly of astronomers from every part of Malik Sháh's wide dominions were employed for several years in reforming the calendar; and their labours, which established the *Jalalean*, or "Glorious Era," is a proof of the attention which was given at this period to the noblest of all sciences. For thirty years after the death of Malik Sháh, Persia was distracted by the wars of his four sons, who contended for the supreme power; but Sanjar having at length triumphed over his competitors, was elevated to the throne. His reign was for a time successful and prosperous. He resided in Khurásán; and from this spot, as from a centre, his dominion extended in one direction beyond the Indus, and in another to the Jaxartes. Towards the latter end of his reign, he experienced the most signal reverses of fortune. Advancing into Tátary, he was completely defeated by the monarch of Kára Kathai, his family were made prisoners, and all his baggage was plundered. He afterwards marched against the Turkamán tribe of Ghaz, who had refused their royal tribute, and in a decisive action which ensued he was defeated and taken prisoner. After being long detained and cruelly treated, he made his escape, and returned to his own country, where the spectacle of his wasted dominions, ravaged and destroyed by barbarous invaders, so preyed upon his spirits, that he died of melancholy in 1175, at the age of seventy-three. After his death, Persia continued during forty years distracted by the wars between different branches of the Seljukian dynasty. The last who exercised sovereign power was Togral III., who was slain by the monarch of Khárazm, as he went into battle flushed with wine.

From the decline of this dynasty to the conquest of Persia by Húlákú Khán, son of the great conqueror Jangiz or Genghis, the country was distracted by the contests of these rival chiefs, who are known under the name of Atábaks. They were petty princes, who, taking advantage of the weakness and anarchy which prevailed, extended their authority over some of the finest provinces of the country. A detailed account of the progress and decay of these various dynasties would exceed our limits; nor would it contain either amusement or instruction. But there is one chief who requires to be noticed, who, by means of assassins devoted to his purposes, caused the most powerful sovereigns to tremble, and spread far and wide the terror of his mysterious power. His followers were reckoned at 50,000; they were called mysterious and devoted; and each was bound, under the most dreadful sanctions, to sacrifice, at the command of their chief, either his own life or that of another. Hasan Sabáh was the first of these chiefs. He had been mace-bearer of Alp-Arslan; but being displeased with his minister Nizámu-'l-Mulk, he retired to Rhe, and afterwards to Syria, where he entered into the service of a chief of the family of Ism'aíl, and adopted their views concerning the right of the descendants of Ism'aíl to the holy dignity of Imám, instead of the younger brother of Ism'aíl. He afterwards returned to Rhe, his native place, where, leaguing himself with other malcontents, he succeeded in gaining possession of the mountain fort of Alláhamaut, whence he commenced a series of depredations on the surrounding country. Malik Sháh Seljukí sent a force against him, which was repulsed. He was soon afterwards exposed to a more serious attack from the Sultán Sanjar, who resolved to extirpate a race whose murders and depredations spread terror over his kingdom. But he was warned to desist from his fatal project by secret threats of assassination. He had made some marches in the direction of Alláhamaut, when one morning as he awoke he discovered a poniard stuck in the ground close to his bed-side, and read with surprise, written on the handle, "Sultán Sanjar, beware. Had not thy character been respected, the hand that stuck this dagger into the hard ground could with more ease have plunged it into thy soft bosom." The warrior who had often faced death in the field of battle trembled at this mysterious threat; and it is certain that he desisted from his meditated attack. Hasan Sabáh brought several other hill-forts under his sway; and was styled Shaikhu'l-Jabal, "Chief of the Mountain," or, as his Arabic title has been erroneously translated, "The Old Man of the Mountain," the name by which he and his descendants are distinguished in the European histories. Khalífs, princes, and nobles fell under the blows of these assassins; and the power and dominions of Hasan Sabáh were handed down through a series of sovereigns who ruled for 170 years, the terror and disgrace of Asia, and who, in 1256, were finally extirpated by the overwhelming and victorious armies of Hulaku Khán, who rivalled his sire in the rapidity of his conquests. His first design was to turn his arms against the declining empire of the Greeks; but he was diverted from this object by an astrologer, who directed his hostility against Baghdád, the seat of the khalíf's authority. This place was speedily stormed by the Tátár armies, and its inhabitants were put to the sword; the Khalíf Mustasim, with his only surviving son, was slain; and thus was for ever extinguished the celebrated empire of the Arabian khalifs. The conquest of Persia, Mesopotamia, and all Syria, was achieved by Húlákú in the same year, who meditated other ambitious schemes of conquest in the East. But the defeat of his army in Syria by the prince of the Mamelukes in Egypt compelled him to abandon his design; and having restored his affairs in Syria, he fixed his residence at Marágha, a beautiful town of Azarbíján, where he spent his declining years in the cultivation of letters and philosophy. He built an observatory on the summit of a mountain, the foundation of which still remains, "and where," says Sir John Malcolm, "his favourite, Násíru-'d-Dín, formed those astronomical tables which have become so celebrated under the name of the Tables

of Il-Khání," and are still referred to for the latitude and longitude of such places as are not fixed by European observations. He was succeeded by Abáká Khán in the year 1264, who was anxious, by cultivating the arts of peace, to repair the ravages of war, and to heal the still bleeding wounds of his wasted empire. He was assailed from the E. by the powerful armies of the Tátár chiefs; but he succeeded in repelling all their attacks, and in maintaining the integrity of his empire. He died, it is supposed by poison, in the year 1281. The Mughul lords having held a council, raised to the throne his brother Nikudár Oglan, seventh son of Húlákú, who, though he was baptized in his youth, afterwards renounced the Christian faith, which he persecuted with all the violence of a renegade, and assumed the name of Ahmad Khán. But his persecution of the Christians was so obnoxious to his own subjects, that they conspired against him, and deprived him both of his crown and of his life. Arghún, son of Abáká, whom he had thrown into prison, was raised to the throne by the Mughul nobles, but did not assume the name until he received the investiture from the emperor of Tátary, by whom he was hailed as sovereign of Persia, Arabia, and Syria. His reign was marked by no event of any consequence; and on his death, which occurred in 1291, his brother Kai Khatú was raised to the throne by the majority of the amírs. The latter was indolent, sensual, and extravagant: and his short and inglorious reign would hardly merit notice, were it not for an attempt by an officer of the revenue department, of known talent, to introduce a paper-currency, in order to supply the means of royal extravagance. But credit, the foundation of paper-currency, cannot exist under a despotism which affords no security either for life or for property. The scheme was therefore altogether vain, and appears to have been the device of a tyrant for cheating or plundering his defenceless subjects. From this period until the conquest of the country by Tímúr Lang or Tamerlane ("Tímúr the Lame"), the history of Persia presents one continued scene of intestine commotion. Tímúr was descended from Korachar Nevian, who had been vazír to Chaghtai the son of Jangíz, and also claimed kindred with that great conqueror. He was counsellor and general to the Tátár prince, Ouleaus Khajah, who ruled over the territories between the Oxus and the Jaxartes. But having soon thrown off his allegiance to this prince, he led a wandering life, with only a few faithful followers, enduring great hardships and peril. He had formed a close alliance with Amír Husain, one of the most powerful nobles of Transoxiana. Their joint object was, to expel the enemies of their country; and Ouleaus, though he had conquered in the field, having been forced to retire with disgrace from the siege of Samarkand, the countries between the Jaxartes and the Oxus were freed from the foreign enemy. A war for the possession of Transoxiana now ensued between Tímúr and Husain, and was only interrupted by a short and hollow peace, which terminated in the overthrow of Husain, who was taken prisoner, and, as is generally believed, put to death, with the secret sanction or by the orders of his rival. Eleven years elapsed before Tímúr had fully reduced to tranquillity his newly-acquired dominions, and had extended his power over Kashgár and Khárazm; after which his whole reign was one unvaried course of the most triumphant success. He subdued Khurásán, Kandahár, and Kábul, and laid the two latter cities under heavy contributions. He invaded Persia, which, being now ruled by the degenerate descendants of Húlákú, was entirely barren and wasted. He extended the limits of his empire to the farthest bounds of Tátary; and whilst one body of his troops spread dismay to the wall of China, another army penetrated to the banks of the Irtisch, and a third to the Volga. Tímúr next marched against Baghdád, which he stormed, and also took the remarkably strong fortress of Takrít; after which his vast armies were dispersed over Asia Minor, Mesopotamia, Kurdistán, and Georgia. He afterwards invaded Russia, and, advancing to Moskow, took and plundered that city. Returning to his own country, he prepared for the invasion of India. His war with Baiazíd or Bajazet, and his defeat and capture of that warlike chief, were amongst the latest exploits of his active reign; and he had embarked on the arduous enterprise of the conquest of China, when he was arrested by an enemy which he could not conquer. He was seized with a violent illness at the city of Otrar, where he expired in 1405, declaring Pír Muhammad Jahángír his successor. The latter, however, had a competitor for the crown in Khalíl Sultán, his cousin, by whom he was deposed and murdered; and, in his turn, Khalíl, infatuated by his attachment to the beautiful Shádu l Mulk, on whom he squandered the vast treasures of Tímúr, was deposed by the nobles. He was attached to the arts of peace, a philosopher, a man of science, and a poet; and his whole care was to heal the wounds inflicted on his country by the wars of the former reign. He rebuilt Hírát and Marv, and drew around him from all quarters men of literature and science. Sultán Sháh Rukh, uncle of Khalíl Sultán, hearing of the misfortunes of his nephew, marched from Khurásán, and his authority was acknowledged over all Transoxiana. Kalíl Sultán was succeeded by Ulugh Beg, who also followed the arts of peace, and neglected those of war. He was deposed and put to death in the year 1449, by his son 'Abdu'l Latíf, who was slain by his own soldiers within the short period of six months. The Mughul dynasty in Persia was now fast verging to decay, and its final extinction was preceded as usual by scenes of confusion and civil war. The kingdom was at length divided amongst three sovereigns,—viz., Sháh Rukh Mírzá, a descendant of Tímúr, who kept a splendid court at Hírát, and governed Khurásán; Kara Yúsuf, the Turkamán chief of the Black Sheep (the tribes of the Black and White Sheep being so called from their carrying the figures of those animals on their respective standards), ruled over Azarbíján, 'Irák, Fárs, and Karmán; and Azan Hasoun, chief of the Turkamáns of the White Sheep, who finally acquired possession of all Western Persia, and attacked the Emperor Muhammad II., from whom he sustained a severe defeat. After his death the country was distracted by the contentions of his sons, grandsons, and nephews, for the supreme authority, and their dissensions, whilst they accelerated their own ruin, prepared the way for a native dynasty, which was gladly hailed by the people as the auspicious omen of domestic peace.

Sháh Ism'aíl was the first monarch of the Safávean line. He traced his descent from Musa Kázim, the seventh imám. The first of the family who attained to any celebrity was Shaikh Safíu-'l-Dín, who resided in the town of Ardebíl, and from whom the dynasty takes its name of Safávean. His son Sadru-'d-Dín inherited all the sanctity of his sire. The great conqueror Tímúr even condescended to visit him in his cell, that he might receive his blessing; and on his asking whether he, Tímúr, could do aught for his comfort, "Give up," replied the saint, "those Turks whom thou hast carried off as captives." The disinterested request was granted, the saint was dismissed with presents, and the descendants of these captives ever afterwards acknowledged their gratitude by their ardent support of the Safávean dynasty. The immediate descendants of Sadru-'d-Dín, Khwájah 'Alí, Junaid, and Haidar, acquired also a great reputation for sanctity. The first, after making the pilgrimage to Makka, visited Jerusalem, where he died. His grandson Junaid assumed the sacred mantle or patched garment worn by the Súfí teachers, after his father's death; and so numerous were his disciples, that Kára Koinlu, who at that time ruled in Azarbíján, took the alarm, and banished him from Ardebíl. He returned to Shírwán, where he was killed by an arrow in a conflict with the troops of that province. He was married to a sister of Azan Hasoun, chief of the Turkamáns of the White Sheep; and this lady was the mother of Sultán Haidar, who succeeded him, and became a warrior as well as a saint. His uncle Azan Hasoun gave him his daughter in marriage, by whom he had three sons, Sultán 'Alí, Ibráhím Mírzá, and Sultán Sháh Ism'aíl. Haidar was defeated and slain in an attack which he made on the province of Shírwán in order to revenge his father's death. Sultán 'Alí succeeded; but he and his brothers were seized at Ardebíl, by Yákúb, one of the descendants of their grandfather Azan Hasoun, who had become jealous of their influence, and confined in a fort, where they remained prisoners for four years. They afterwards made their escape, and were soon joined by numerous adherents. But in the meantime they were attacked, Sultán 'Alí was slain, and his brothers fled in disgrace to Gílán, where Ibráhím Mírzá died. These events occurred during the infancy of Ism'aíl, the third son of Haidar, of whom we know little till he attained the age of fourteen, when he collected his adherents, and marched against the great enemy of his family, the ruler of Shírwán, whom he defeated. Alwand-Beg, a prince of the dynasty of the White Sheep, hastening with his troops to crush the young warrior, shared the same fate; and the triumphant prince having made himself master of the province of Azarbíján, fixed his residence at Tabríz. Next year he vanquished Sultán Murád, one of the military competitors for supreme dominion in Persia; and in less than four years from his leaving Gílán he was acknowledged the sovereign of Persia.

Sháh Ism'aíl, not being born the chief of a tribe, had no hereditary feuds to avenge; his family were objects of hostility to no one; and he united in his person the reverence and affection of all his subjects. He was a firm adherent of the Shí'ahs. The Turkish tribes to whom he owed his elevation were highly honoured. They were distinguished by a red cap, from which they received the name of Kazilbásh, or "red heads," which has descended to their posterity. Persia, Khurásán, Baghdád, and Balkh, submitted to his arms. His territories were afterwards invaded by Sultán Salím about the year 1514, with a numerous and well-disciplined army. In the action which took place, the Persian monarch, after performing prodigies of valour, was entirely defeated, which affected him so deeply that he was never afterwards seen to smile. After the death of Salím he crossed the Araxes, wrested Georgia from the possession of Turkey, and died at Ardebíl in the year 1523. He was succeeded by his son Támásp, who ascended the throne when

he was only ten years of age. His reign, which continued fifty-three years, proved prosperous. He repelled the invasions of the Uzbaks on the east, and of the Turks on the west. It was from him that Humáyún, emperor of India, when he fled from his rebellious subjects, received the aid which enabled him to regain his throne. It was to him also that Elizabeth sent her envoy, Anthony Jenkinson. But the intolerance of the Muhammadan monarch could not brook the presence of a Christian. His family was numerous; and after several years of disputed succession, and of brief and troubled reigns, 'Abbás, his grandson, was proclaimed king in 1582, when a minor. During the earlier years of this monarch's reign, the country was alternately alarmed by internal disturbance and foreign aggression, each party in their turn using the name of the sovereign. But as he advanced to manhood he vindicated his rights, and in the course of three years he reigned the undisputed sovereign of the country. His reign, which lasted forty-three years, was highly successful and glorious. He was engaged in wars with the Turks and with the Uzbaks, whose armies he defeated in several actions; and it was during his time that an amicable intercourse commenced between Persia and Europe.

Sir Anthony Shirley, a gentleman of family, was persuaded by the Earl of Essex to repair to the court of Persia; and, with twenty-six followers, gallantly mounted and richly attired, he presented himself to the king, who received him with every mark of distinction. The military skill of these foreigners enabled him to discipline his army and to improve his artillery, so that with an army of 60,000 warriors he obtained a decisive victory over 100,000 Turks. In this battle, which was fought on the 24th of August 1605, Sir Anthony Shirley was thrice wounded. This victory gave a decided check to the Turks, who were driven from Azarbíján, Georgia, Kurdistán, Baghdád, Mosul, and Diarbekir, all of which were re-annexed to the Persian empire. This monarch also entered into an alliance with the English for the destruction of the flourishing Portuguese settlement of Hurmaz, which unhappily proved but too successful; and this place, long renowned as the seat of wealth and a great commercial emporium, was plundered and left to decay.

'Abbás expended his revenues in the improvement of his dominions, and erecting caravanserais, bridges, aqueducts, bázárs, mosques, and colleges; he embellished Isfahán, his capital, built splendid palaces, the ruins of which still attest his taste and magnificence. He was also distinguished by his toleration, especially to Christians; and he was liberal in his foreign policy. To his family he proved a sanguinary tyrant. He had four sons, whom he caressed, whilst in infancy, with parental fondness, but who, as they arrived at manhood, were viewed with jealousy and hatred. The oldest son was assassinated, and the eyes of his other children were put out, by his orders. One of these, Khudábandah, had a daughter, Fátimah, innocent and lovely, and the delight of her grandfather, who could not endure that she should be out of his sight. The prince, learning the fondness of his father for this his child, seized her one day with all the fury of a maniac, and deprived her of life. The rage and despair into which 'Abbás was thrown by the death of his grand-daughter gave a momentary joy to the son, who concluded this bloody tragedy by swallowing poison. 'Abbás died soon afterwards, in 1628, at the age of seventy, worn out with affliction of mind.

By the desire of the expiring prince, Sám Mírzá, one of the sons of Sáfi, who had been murdered, was placed on the throne, which he occupied fourteen years. His son 'Abbás II. succeeded him at the age of ten, and reigned prosperously twenty-five years, though his habits were licentious and intemperate. He was succeeded by his eldest son 'Abbás in the year 1641, who, under the title of Sháh Sulaimán, reigned twenty-nine years. He was, like his father, the slave of dissolute habits; and his drunken orgies were often stained with blood. He was succeeded by Husain Mírzá, a weak prince, who was ruled by eunuchs and priests, and whose measures tended to destroy the little spirit which yet lingered amongst the nobles and chiefs. The first twenty years of his reign passed over in tranquillity, but it was only the prelude to a political storm. The Afghán tribes who inhabit the mountainous tract between Khurásán and the Indus had long been subject to Persia, and having often suffered great oppression, at length broke out into rebellion, irritated by the tyranny of Gurjin Khán. The insurgents were headed by Mír Váiz, an Afghán chief. They invited the obnoxious governor Gurjín Khán to a feast, where he was suddenly attacked and put to death; and Mír Váiz, collecting his followers, surprised and stormed the fortress of Kandahár. He then proceeded to strengthen himself in his newly-usurped power. Whilst the weak monarch endeavoured by negotiation to pacify this formidable insurgent, Mír Váiz imprisoned his ambassabor, and set his power at defiance; and a second ambassador met with no better treatment. The court of Persia now assembled an army under the command of Khusrau Khán, who advanced against Mír Váiz, defeated his army, and laid siege to Kandahár. The insurgent chief having assembled another army, compelled the Persian general to raise the siege of that place, and afterwards defeated him in a decisive action, in which he was slain. In the midst of his successes Mír Váiz died, and was succeeded by his brother Mír Abdu'lláh, who was assassinated by Mahmúd, son of Mír Váiz. The troubles which now afflicted Persia on every side gave ample leisure to Mahmúd to mature his plans, and to consolidate his power. The Uzbaks were ravaging Khurásán; the tribes of Kurdistán were almost at the gates of Isfahán; the Abdali Afgháns had taken Hírát, and afterwards Mashhad; the islands in the Persian Gulf had been subdued by the Arabian governor of Maskat; and the rude tribes of Georgia had attacked Shírwán. A prediction by an astrologer, of the total destruction of the capital by an earthquake, completed the public dismay, when intelligence was received that Mahmúd Ghilzy had entered the country at the head of 25,000 Afgháns. He was met by the royal army of 50,000 troops; and an action took place, which ended entirely in favour of the Afgháns. The consequence was, the siege or blockade of Isfahán, which, after enduring all the miseries of famine, surrendered on the 21st of October 1722, after a siege of seven months. The following day the fallen monarch of Persia, Husain, took a solemn leave of his subjects, and signed a capitulation, by which he resigned the crown to Mahmúd. Husain, with his nobles, after doing homage to the Afghán sovereign, was confined for seven years in a small palace, when his enemies, threatened with a reverse of fortune, caused him to be assassinated; and in his person may be said to have terminated the Safávean dynasty, as his son, Támásp, though he assumed the title of king, never possessed any real power, and only struggled a few years against his inevitable fate.

Mahmúd having thus succeeded in acquiring the sovereignty of Persia, now endeavoured to conciliate the people whom he had subdued. But the Persians hated the Afghán yoke; and, as they recovered from their first dismay, they began to attack and cut off scattered parties of the invaders. At the same time Persia was invaded both by Russian and Turkish armies. The Russian army advanced into the country and took possession of Darband, and the Turkish army was already on its march to Hamadán, when the inhabitants of Kazvín rose in insurrection, and expelled the Afghán garrison from the place. Mahmúd was now seriously alarmed. The probable revolt of the capital seemed to be the most immediate danger; and his gloomy mind, alarmed and enraged by these signs of vengeance, conceived the horrible design of exterminating the conquered people. He commenced with the massacre of three hundred nobles and their children, who were treacherously invited to a feast. He afterwards put to death three thousand of the late king's guards, whom he had taken into his pay; and at length every person who had been in the service of Sháh Husain was included in one bloody proscription, and put to death without mercy.

After this, Mahmúd, being aided by the Kurdish tribes, succeeded in making himself master of some of the principal cities of 'Irák and Fárs. But his affairs appeared to be on the decline; his kingdom was threatened from various points, and his mind proved at last unequal to the difficulties with which he was assailed. In this extremity he resorted for relief to the most abject and degrading superstitions; he shut himself up in a vault for fourteen days and nights, fasting and enduring the severest penances; and, under the influence of this gloomy fanaticism, he lost his reason, and fell into the most furious paroxysms of madness. In this melancholy situation his mother, out of compassion to him, directed him to be smothered. But this event did not take place till, under his fatal orders, thirty-nine princes of the Safávean blood had suffered an untimely death. He was succeeded by Ashráf, the son of Mír Abdu'lláh, and nephew of Mír Váiz. The first period of Ashráf's reign was successful. He gained repeated victories over the Turkish armies, who were compelled to retire; and he concluded the war by compelling the Turkish court to acknowledge his title to the throne. But he was now assailed from another quarter by more serious dangers. Támásp, the son of Sháh Husain, and the representative of the Safávean princes, was in Mazandarún, where he was joined by a distinguished chief, Nádir Kulí, a well-known warrior, who now declared his resolution to expel every Afghán from the soil of Persia. Támásp, from the day of his father's abdication, had assumed royal state, and now that he was supported by Nádir and the nobles of Khurásán and the Mazandarún, he found himself in a condition to exercise the authority of a sovereign. Nádir being invested with the sole command, soon succeeded in reducing Mashhad and Hírát, and at length all Khurásán, under the authority of Támásp. Ashráf now prepared for the defence of his sovereign authority; and having raised an army, he advanced into Khurásán against his enemy, whose followers, he knew, were daily increasing. The Afgháns were defeated in a series of sanguinary actions, and pursued, first to Tehrán, and finally

Persia.

to the gates of Isfahán. It was at first proclaimed in the city that the Afgháns had obtained the victory; but the loud wailings of the women from the citadel soon disclosed the result of the battle. The night was passed in preparations for flight. The old men, women, and children, were mounted on mules and camels, and having packed up all the treasure and spoil which they could carry away, they took the route to Shiráz by break of day; the tyrant Ashráf having in the meantime cruelly murdered Sháh Husain, who was still detained a prisoner, and the pressure of circumstances only preventing a general massacre, which was fully intended. Nádir lost no time in pursuing the discouraged and flying Afgháns. They were overtaken at [illegible], and immediately fled towards Shiráz, where, though they were still 20,000 strong, they were deserted by their leader, who fled homewards with only two hundred followers. The army was dispersed in wandering bands, which were closely pursued and cut down by their exasperated foes; and Ashráf himself, whilst wandering in Sistán, was recognised and slain by Abdulláh Khán, a soldier of Bilúchistán, who sent his head, with a large diamond which he found on his person, to Sháh Támásp. The Afghán invasion was one of the most cruel calamities which ever befel the Persians. Within the short period of seven years they had massacred nearly a million of the inhabitants, laid waste the finest provinces of the country, and levelled the proudest edifices with the dust.

Nádir Kuli, afterwards known as Nádir Sháh, was born in the province of Khurásán, on the 11th of November 1688. His father was in a low condition, earning a livelihood by making coats and caps of sheep-skins. He was taken prisoner by the Uzbaks at the age of seventeen, but made his escape from them after a captivity of four years. He was for a considerable period the chief of a band of robbers; and being a plunderer of known valour and resolution, had collected 3000 followers, by whose aid he laid under contribution the extensive province of Khurásán. His friendship was now courted by his uncle, who was the chief of Kelát. Nádir pretended to listen to his overtures, but treacherously slew him with his own hands, and proceeded to employ the power which he had thus acquired against the Afgháns, the enemies of his country. And so well did he succeed in this popular and patriotic enterprise, that the Afgháns were entirely expelled from the country; whilst, for his services, he received from his sovereign, Támásp, the provinces of Khurásán, Mazandarún, Sístán, and Karmán. He then proceeded to attack the Turks, who still occupied the western provinces of 'Irák and Azarbíján, and having defeated them in various actions, took possession of Tabríz, Ardebíl, and all the principal cities. He returned to quell an alarming insurrection of the Afgháns, who were unable to withstand his victorious armies; and in the meantime the imbecile Támásp commenced a war with the Turks, which ended in a disgraceful peace. He had for some time been a mere pageant in the hands of Nádir; and this unfortunate war, with other complaints against him, furnished a plausible pretence for his dethronement, which took place on the 16th of August 1732. He retired to Khurásán, where he was afterwards put to death by Rizá Kulí, the son of Nádir, with the knowledge, if not by the secret orders, of the father. His son, an infant eight months old, was seated on the throne; but Nádir was now in substance, as he was soon to be in form, the real sovereign. In 1736 the death of this infant removed the only obstacle to his ambition; and in a vast assembly of his nobles and troops, he was, after much pretended reluctance, prevailed on to accept of the crown. This high dignity served only to give a fresh stimulus to his active and enterprising habits. In the course of a new war with the Turks, after having regained the provinces which had been wrested from the imbecile Támásp, and concluded a peace, he turned his arms eastward. Kandahár and Balkh were besieged and taken by his son Rizá Kulí, who passed the Oxus, and defeated the ruler of Bukhára and the Uzbaks. Afghánistan was afterwards subdued; and Nádir finally completed his military glory by the conquest of Delhi. A single battle was sufficient to disperse the Mughul host; and Nádir, with his triumphant legions, entered the capital, which made no resistance. Its treasures were plundered; and its inhabitants, who rose on the Persian soldiery, were, in revenge, given over to an indiscriminate massacre, in which neither age nor sex was spared. Nádir returned in triumph, loaded with the spoils of one of the richest capitals of the East. He continued to prosecute his conquests on every side, and restored the ancient glory of the Persian empire, when it extended from the chain of the Caucasus eastward to the Indus.

But the glory of foreign conquest was tarnished by domestic tyranny. In an expedition against the Lesghís, a mountain tribe upon the western frontier, Nádir was wounded by an assassin, who fired on him from a wood. His suspicion fell on his son Rizá Kulí, or had been instilled into his mind by artful intriguers. Under this impression he commanded his son into his presence, and immediately caused him to be deprived of his eyesight. But so struck was he with remorse after the deed had been done, that he vented his fury upon all around him; and fifty noblemen were put to death by his orders, because they had not come forward to sacrifice their lives for the young prince, the hope of his country. "It is not my eyes," says the prince, 'that you have put out, but those of Persia.' The mind of Nádir was deeply affected; he became gloomy and ferocious; all his future actions were deeds of horror, and he exceeded in barbarity all that has ever been recorded of the most bloody tyrants. The country languished under his extortions; and when he at last raised the people to insurrection, his fury knew no bounds, and he not only murdered individuals, but gave up whole cities to the destroying sword. Several of the principal officers of his court, [illegible] that their names were in a proscribed list, resolved to anticipate the vengeance of the tyrant. The execution of the plot was committed to four chiefs who were employed about the palace, and who, on the pretext of business, rushed past the guards in the inner tents, and found the tyrant asleep. He was awakened by the noise, and had slain two of the conspirators, when he was deprived of life by a blow from Sálah Beg, the captain of the guards.

The sudden death of Nádir Sháh involved the country in the greatest distraction. He was succeeded by his nephew 'Ali, who took the name of Adil Sháh. But his reign was short and inglorious. He was taken prisoner by his brother Ibrahím Khán, and put to death at Mashhad, as his captor himself also was, being slain by the officer who guarded him. Sháh Rukh, the grandson of Nádir, succeeded; but the throne was ere long usurped by Mírzá Saiyíd Muhammad, by whom Sháh Rukh was taken prisoner and deprived of sight. The usurper being defeated and taken prisoner by Yúsuf 'Alí, the principal general of Sháh Rukh's army, was immediately put to death. The blind Sháh Rukh was again raised to the throne; but the measures of his general, Yúsuf 'Alí were opposed by two chiefs, the respective heads of a Kurdish and an Arabian tribe, and, by their joint efforts, the faithful general of Sháh Rukh was defeated and slain, and he himself again sent from a throne to a prison. The two chiefs, however, soon quarrelled; and Mír 'Alam, the Arabian, triumphed, but only to fall before the rising power of the Afgháns under Ahmad Khán 'Abdalí. This leader might at the time have easily accomplished the reduction of Persia. But judging more wisely, he assembled the principal chiefs, and proposed to them that the province which gave birth to Nádir should be given as a principality to his grandson. To this all the chiefs agreed, and Sháh Rukh was again established in the undisturbed possession of Khurásán. At this period Persia was in a complete state of distraction, from the contentions of rival chiefs. Muhammad Husain Khán, chief of the tribe of Kájárs, had established himself at Astarábád, and had brought under his authority the whole province of Mazandarún. The province of Azarbíján was under the rule of Azád Khán, an Afghán leader, who had been one of the generals of Nádir Sháh. Gílán was independent, under one of its own chiefs, Hidáyat Khán. At this time 'Alí Mardán Khán, a chief of the tribe Bakhtiyárí, took possession of Isfahán, and, resolving to elevate a prince of the house of Safí to the throne, he invited the nobles to join his standard. The principal of those chiefs was Karím Khán, of the tribe of Zand, a man distinguished by his sagacity and courage, and between whom and 'Alí Mardán Khán a rivalship for power soon took place. Karím Khán, dreading the enmity of 'Alí Mardán, took the field against him. But his assassination soon afterwards left Karím undisputed master of the south of Persia. He was joined by most of the tribes from that country, and being at war with Azád Khán, he was entirely defeated by him in a general action, and so discouraged by the unpromising state of his affairs that he meditated a retreat into India. But he was dissuaded from so unworthy a course by the remonstrances of his general Rustam Sultán, the chief of Khisht, who attacked the enemy in a narrow pass, and obtaining a complete victory, re-established the power of Karím Khán, who again occupied the city of Shíráz, where he employed his utmost efforts to recruit his army. Azád Khán, throwing himself on the clemency of his conqueror, was received into his service, and became one of his most attached followers. The most powerful enemy of Karím Khán was Muhammad Husain Khán, the chief of the Kájárs, who ruled in Mazandarún. He advanced against Shíráz with a powerful force; but the city being bravely defended, he was compelled to raise the siege, and to retreat to Isfahán. He afterwards engaged Karím in a general action, in which, being deserted by part of his troops, he was defeated and slain. The whole province of Mazandarún then submitted to the conqueror, and this was followed by the submission of Gílán and the greater part of Azarbíján. Khurásán was the only province which he did not subdue; and his forbearance is ascribed to compassion for the blind Sháh Rukh, who still retained this remnant of his extensive dominions.

Karím Khán was distinguished by a love of justice and a moderation not usual amongst eastern princes. He died in the year

1779, in the eightieth year of his age, after a reign of twenty-six years. His administration was generally just and beneficent. He encouraged agriculture and commerce, which greatly revived during the latter years of his reign; and he protected by his justice Christians as well as Muhammadans. He never refused mercy to a fallen foe, though he sometimes punished severely, that he might strike terror into his enemies. The humane disposition of this prince prompted him to acts of mercy; and the generous confidence with which he treated those whom he forgave never failed to attach them to his person.

After the death of Karím Khán, the succession to the crown was, as usual, disputed, and in the course of these contests his four sons either perished under the daggers of assassins, or were sacrificed in the intrigues of ambitious chiefs contending for the crown. Zakí Khán, the moment his father died, assumed the reins of government, whilst Sadak Khán at the same time evacuated Basrah, and advanced towards Shíráz. But he was unable to contend against Zakí, and was soon forced to retire. In the meantime, Aghá Muhammad Khán Kájár, who had been detained prisoner at Shíráz, and who was duly apprised by his sister, an inmate of the royal harem, of the progress of Karím Khán's illness, and at last of his death, contrived to escape to Mazandarún, where he proclaimed himself a competitor for the throne. The cruelties of Zakí, who had treacherously murdered a number of his rebellious nobles, after pledging his faith for their safety, soon provoked revenge, and he himself was put to death at Yezdikhast. Abú'l Fath Khán was proclaimed king of Persia the moment Zakí Khán was put to death. Sadak Khán hastened from Karmán to Shíráz when he heard of the assassination of Zakí and proclaimed himself king, arresting the person of Abú'l Fath Khán, and causing his eyes to be put out. He was besieged in his capital by his nephew 'Alí Murád Khán, his most formidable enemy, and, being obliged to surrender, he was put to death, with most of his sons. 'Alí Murád was, in his turn, put down by another rival; and Jafar Khán, nephew of Karím, and Aghá Muhammad, were at length the only rivals left to contend for the crown. The former having disgusted one of his chief supporters, Hájí 'Alí Kulí, he engaged in a conspiracy against him; and having put poison in his victuals, he and others rushed into his chamber when he was writhing under its effects, and put a period to his existence. He was succeeded by Lutf 'Alí Khán, who was one of the most remarkable characters recorded in the Persian annals. His appearance was greatly in his favour: his fine countenance full of animated expression; his form tall and graceful, and, though slender, active and strong. He was at Karmán when he heard of his father's murder, which took place in the year 1789; and though Saiyíd Murád Khán was at first proclaimed king by the conspirators, yet, by the aid of Hájí Ibráhím, appointed by his father the first magistrate of the province of Fárs, he was soon enabled to assert his claim to the crown. He was bold in counsel and fearless in action, and maintained a long and well-sustained struggle for the sovereignty, in the course of which he performed prodigies of valour. But he wanted prudence and temper, and had no control over his passions. Unbending in his pride, and harsh and unconciliating in his manners, he employed terror as the chief source of his influence. His great error was in quarrelling with and disgusting his faithful minister Hájí Ibráhím, a statesman of consummate prudence and talents, who abandoned his service for that of his rival and enemy, Aghá Muhammad Khán, and was ever afterwards his most formidable enemy.[1] Lutf 'Alí maintained the contest for six years; but he was at length overwhelmed by the superior forces of his enemy. Flying from Persia, he was treacherously seized, after a brave resistance, in which he was seriously wounded, and being delivered into the hands of Aghá Muhammad Khán, was treated with a brutality of insult which is too shocking to be described, and which, Sir John Malcolm adds, disgraced human nature. His eyes were torn out, and he was sent to languish out a miserable existence in Tehrán, where an order was soon afterwards sent for his execution. Lutf 'Alí terminated his extraordinary career in 1795, in the twenty-fifth year of his age. Nor was Aghá Muhammad's cruel treatment of the inhabitants of Karmán less shocking. This place was the last stronghold of Luft 'Alí. It was defended by him with his usual bravery, and being at length taken by treachery, became the scene of the most dreadful atrocities. The place was almost depopulated. Many women and children, to the number of 20,000, were carried into slavery. The men were murdered, and numbers were deprived of sight, many of whom were afterwards seen by Sir John Malcolm begging their bread. Lutf 'Alí was the last of the Zand family of princes, who had ruled over Persia for nearly half a century.

Aghá Muhammad Khán having now firmly established himself upon the throne of Persia, his first care was to restore order throughout his dominions, and to repel foreign aggression. Having tranquillized the southern and central provinces, he invaded Armenia and Kárabág, and, marching straight to Teflis, he defeated Heraclius, prince of Georgia, and having taken the city, he sacked it, and made a dreadful slaughter of the inhabitants, carrying into slavery 20,000 women and children. He then turned his arms eastward, subdued Khurásán, and repressed the incursions of the pillaging Turkamáns in the vicinity of Astarábád, as well as of the Uzbaks in Bukhária. But however rigorous his administration, and however active in the field, all his exploits were stained with cruelties. His avarice was unbounded; and he scrupled at no atrocity to gratify it. He had long thirsted after the jewels of which Nádir Sháh had despoiled India, and these he wrested without remorse from their unfortunate possessors. From the aged and blind Sháh Rukh he extorted, by the severest tortures, several of those which were the most precious, particularly a ruby which had belonged to Aurangzíb, and which was of extraordinary size and value. This precious jewel was retained to the last, until boiling lead had been poured upon the head of the unhappy prince, when, in his intolerable agony, he declared where it was hidden. He was afterwards conveyed to Damghán in Khurásán, were he died in a few days, in the sixty-third year of his age, in consequence of the tortures to which he had been subjected.

Aghá Muhammad Khán succeeded in tranquillizing the country, partly by policy, and still more by terror. He often spared his enemies, and conciliated them, not however from any feelings of humanity, but from a sense of his own interest, for his disposition was stern, cruel, and vindictive, and his reign presents a series of atrocities scarcely equalled in the bloody annals of the East.

'Alí Khán, a chief of the Afshár tribe, had opposed Aghá Muhammad in the field. He was decoyed into his power by the deepest treachery, and being arrested amidst fawning and caresses, his eyes were put out. The brave and generous Jafar Kulí, his own brother, was in like manner seduced, by the kindest assurances, to visit the court of Tehrán, where, after being welcomed with every appearance of cordiality, he was cruelly assassinated. This act stamps upon Aghá Muhammad the character of a remorseless tyrant. In truth, a temper naturally cruel had been still more soured by cruelties he had himself undergone in his youth.

Aghá Muhammad being apprised of the invasion of Persia by Russia, sent his army to defend the frontier; but the death of the Empress Catharine relieved Persia from the serious danger with which it was threatened. Aghá Muhammad then determined to move towards Georgia; and having received a friendly deputation from the inhabitants of Shíshah, he proceeded with some light troops, and took possession of this important fortress. Three days afterwards, a dispute having occurred between a Georgian slave, a personal attendant on the monarch, and another servant, respecting some money that was missing, the king, enraged at the noise which they made, directed that they should both be put to death. Saadak Khán Shekákí, a nobleman of the highest rank, solicited their pardon, which was refused; but as it was the night of Friday, sacred to prayer, their lives were spared till next morning, and, with a singular infatuation, the despot permitted them to perform their usual services about his person. Despair gave them courage; and whilst the monarch was asleep, they entered his tent, accompanied by an associate, and stabbed him with their poniards. He was then in the sixty-third year of his age, and had ruled for upwards of twenty years, though he had enjoyed the undisputed sovereignty of the country for only a small portion of that time.

Aghá Muhammad was in person so slender that he appeared like a youth of fourteen or fifteen. His face was beardless and shrivelled, resembling that of an aged and wrinkled woman; it was at no time pleasant or agreeable, and when clouded with indignation, as it often was, its expression was horrible. He was so sensible of this that he could not bear any one to look at him. He was harsh and abrupt, and often cruel to his ministers and to his domestics. Hájí Ibráhím, however, was uniformly treated with unbounded confidence. "The penetration of the monarch," says Sir J. Malcolm, "discovered at once the talents of that extraordinary man, whose plainness of manner, blunt speech, manly fortitude, and astonishing knowledge of public affairs, led Aghá Muhammad to give him his entire confidence, and no confidence was ever better rewarded. The minister, though he contrived to gratify the avarice of his master, and to promote his ambition, often obtained favour for others through the kindness of his disposition, whenever he could interfere without danger to himself."

By the influence and wise management of Hájí Ibráhím, the

[1] See, in Sir John Malcolm's excellent *History of Persia*, a full account of all the transactions of Lutf 'Alí's reign. Sir John was personally acquainted with Hájí Ibráhím, who informed him that his principal reason for taking part with Muhammad Khán was to save his country from the continual petty wars with which it had been long afflicted. (Vol. ii., chap. xix., p. 183.)

crown was secured to the nephew of the deceased monarch, who assumed the sovereignty under the title of Fath 'Alí Sháh. Saadak Khán made a feeble effort to oppose him, but was attacked and defeated. Two other attempts to usurp the crown, the one made by the king's brother Husain Kulí Khán, and the other by Muhammad Khán, a prince of the Zand family, were subdued; and since this period the internal tranquillity of the country has not been disturbed. The most important events in the reign of Fath 'Alí were connected with the wars which he entered into with Russia, and which generally proved unfavourable to Persia. In 1800 Georgia finally submitted to the dominion of Russia; and in 1803 Mingrelia was subdued. Gunjah was taken; and although the invaders were forced to raise the siege of Eriván, they overran Dághistán and Shirwán; and in 1805 Kárabág yielded to their victorious arms. The interference of Great Britain arrested the progress of Russian conquest; and Persia was saved from further inroads by the treaty of Gulistán, concluded in October 1813, which fixed the relative boundaries so indefinitely, as, after much tedious negotiation, to give rise to a new war. In this war, which commenced in the month of July 1826, 'Abbás Mírzá, the prince royal of Persia, took the field, with 40,000 men, 12,000 of whom were regulars; and at the outset he gained several important advantages. But the superior discipline of the Russian armies, trained in the wars of Europe, triumphed in the end; and in 1828, seeing no prospect of maintaining the war with success, peace was again sought for through the mediation of Great Britain. It was concluded on the 21st of February at Turkamánchai. Besides large cessions of territory,—namely, the Khánat of Eriván, and that of Nakhshiván, and the greater part of Talish, including all the islands which fall within its direction,—Persia agreed to pay 5,000,000 of tumáns, as an indemnification for the expenses of the war. Since this treaty the peace of the two countries has not been disturbed; and the prince royal, turning his attention to the internal concerns of his kingdom, has succeeded in reducing the rebellious chiefs of Khurásán. By the aid of a Polish refugee, equally skilful and brave, he acquired possession of Yeza, took Turshish and Khabushan by storm, and reduced to obedience all the other chiefs in that quarter.

Fath 'Alí Sháh was about forty years old when he succeeded his uncle Aghá Muhammad on the throne. He reigned nearly thirty-eight years, and died in October 1834. With the exception of his wars with Russia, the tranquillity of his long reign was almost undisturbed. By the treaty of Turkamán Chai in 1828, the Russian frontier had been advanced to Mount Ararat, and thence to the left bank of the Aras. This acquisition was regarded by Russia as only a step to further advances, and as soon as Muhammad Sháh, the eldest son of 'Abbás Mízá, had been securely settled on the throne of his grandfather, Fath 'Ali, the Russian minister at Tehrán, commenced a series of intrigues to induce the new sháh to advance against Hírát. As the sháh had been placed on the throne by the aid of English arms and influence, in opposition to the efforts of his numerous uncles and nephews, this movement, so contrary to the interests of the British, was a piece of base ingratitude. The sháh was fully aware how displeasing any attempt upon Hírát would be to the English government; for in 1832 Fath 'Alí had been induced by the English envoy to abandon an expedition against that city, in spite of the encouragement of the Russians, who even sent Baron Ache, an officer of engineers, to accompany it. In the winter of 1835, however, Muhammad Sháh announced his intention to march against Hírát in the spring; and Mr Ellis, the English ambassador, used every effort to dissuade him, and to compose the differences between the sháh and the ruler of Hírát, Prince Kámrán. Nevertheless, the sháh persevered in his intention, and marched, accompanied by the Russian minister, in August 1836; but having attacked the Turkamáns on his way, his army was so much harassed by them as to be obliged to return towards Persia in October of the same year. About this time Sir John M'Neill had replaced Mr Ellis at the court of Tehrán, and continued to remonstrate with the sháh on the subject of Hírát. On the 23d of July 1837, however, the sháh marched again against Hírát; and on the 10th of October Captain Vicovich, a secret agent of the Czar, joined the Persian camp, and proceeded thence to Kandahár and Kábul, announcing that a Russian force had arrived at Astarábád to co-operate with the sháh. This report had such an effect upon the Afgháns, that it was thought requisite to recall the British agents, Major Leech from Kandahár, and Captain A. Burnes from Kábul. Kohandil Khán, the ruler of Kandahár, now bound himself by treaty to become the subject of Persia, and the Russian minister, Count Simonich, took the command of the Persian troops in the trenches before Hírát, and a regiment of Russian deserters were allowed to take part in the assault. The siege of Hírát lasted ten months, and the defence was one of the most memorable in history. The sufferings of the inhabitants were dreadful; and the population was reduced from 70,000[1] to about one-tenth of that number. But every assault was repulsed, chiefly through the courage and skill of Lieutenant Eldred Pottinger, an officer of the East India Company's artillery. At the same time the Anglo-Indian government, to counteract the designs of Persia, despatched an armament to occupy the island of Kharg in the Persian Gulf, and concluded a treaty with Sháh Shujá'a and Ranjít Singh to depose the Bárakzy chiefs, Kohandil and Dost Muhammad, and place Sháh Shujá'a, the ally of the British, on the throne of Kábul. This treaty was signed on the 26th of June 1838; and the whole of Afghánistán was shortly after occupied by British troops. These operations, and the determined defence of Hírát completely overthrew the ambitious designs of the sháh. He returned to Tehrán, and the Russian government hastened to disavow all intentions hostile to the British. In 1839 a Russian army of 15,000 men marched from Orenburg, under General Peroffski, against Khíva. It had been collected in anticipation of the sháh's success at Hírát, but it failed against Khíva no less signally than the sháh had done in the other direction; and the greater part of the troops perished in the snow. In 1841, immediately after the destruction of the English army at Kábul was known, the Russians again commenced their ambitious movements on the side of Persia. They established a naval station at Ashurada, an island in the Gulf of Astarábád, about 12 miles from the coast, and established a complete supremacy in the Caspian, in which sea they are now supposed to have four or five steamers, and several brigs and schooners of war.

Muhammad Sháh died in August 1848 at Tehrán, and was succeeded by his eldest son, Násiru'd-dín, the present sháh. Colonel Farrant, an English officer serving in Persia, was the main instrument in securing the quiet accession of the new king, and held the capital for him till he arrived from Azarbiján, of which province he was governor. Friendly relations had been renewed between the English and Persian governments; but the subject of Hírát had not been lost sight of by the court of Tehrán. Sháh Kámrán had been murdered by his vazír, Yár Muhammad Khán, and this wily chief had long before engrossed the chief power in that principality. His policy was to maintain independence, while he soothed the sháh by courtesies which cost him little. But in 1851 Yár Muhammad died; and his son Saiyíd Muhammad, less confident of his position, sent envoys to Tehrán offering to become the subject of Persia. In response to these offers, a Persian force was prepared under Sultán Murád Mírzá, the governor of Khurásán, nominally against the Turkamáns, but in reality for the occupation of Hírát. Colonel Sheil, the British envoy, at once remonstrated against this expedition, and on August the 7th, 1851, distinctly announced to the Amír Nizám, or prime minister, that a perseverance in the proposed course would bring on a rupture with Great Britain. After a long correspondence, the Persian government, on the 25th of January 1853, signed an agreement not to send troops to Hírát until that place should be attacked by a foreign force. New difficulties, however, soon arose. In 1854 Mr Thomson, in charge of British affairs, appointed Mírzá Háshem to be first Persian secretary of the mission, an appointment so obnoxious to the sháh that the Persian government declined to receive the mírzá, and, on his destination being changed to Shíráz, notified to Mr Murray, who was now the British minister, that should the mírzá set out for his post, he would be seized, and forcibly detained. This notice was given on the 6th of November 1855, and immediately afterwards the mírzá's wife was seized by order of the Persian minister. On the 17th Mr Murray officially intimated, that unless the lady was released, the flag of the mission would be hauled down, and friendly relations would cease; and as this menace produced no effect, the flag was struck on the 20th of November, and on the 5th of December the mission withdrew from Tehrán. The Persian government then published a justification of its conduct, which set forth that Mr Murray was carrying on an intrigue with the wife of Mírzá Háshem, and in an autograph note to his prime minister the sháh indulged in the most intemperate language against Mr Murray, charging him with insolence, and speaking of him as "stupid, ignorant, and insane." In the same month of December Prince Sultán Murád Mírzá put himself at the head of 9000 men intended to act against Hírát. It must be admitted that there was some colour for this expedition, as a tribute had been guaranteed to the sháh from the city, and, further, Prince Muhammad Yúsuf, the son of Kámrán, who, after putting Saiyíd Muhammad to death, had recovered his heritage, had applied to Persia for aid, alleging that he was threatened with an attack by Dost Muhammad of Kábul. On the 27th of February 1856 the Persian government, doubtless encouraged by the Russian successes

[1] Ferrier's *Caravan Journeys*, p. 171.

Persian Gulf.

at Kárs in November of the preceding year, published their reasons for this offensive movement. After futile negotiations between the Persian envoy at Constantinople and Lord Stratford de Redcliffe, instructions were sent out by the mail of the 20th of September 1856, by Lord Clarendon to the governor-general of India, to prepare a force at Bombay for the occupation of Kharg. In the meantime, the Persian army under Sultán Murád had defeated the Hirát forces near Ghorián, taking their general, Ahmad Khán, and several hundred men, prisoners; and having captured and garrisoned Ghorián, after a twenty days' siege, were closely besieging Hirát itself On the 29th of April 1856 Prince Muhammad Yúsuf was sent in as a prisoner into the Persian camp by his vazír, 'Isá Khán. On the 26th of October 1856 Hirát was surrendered to the Persians, and its occupation was publicly notified at Tehrán on the 6th of November. (*Correspondence respecting Relations with Persia*, p. 228) On the 1st of the same month the governor-general of India issued a proclamation declaring war against Persia. On the 11th several ships sailed with troops from Bombay for the Persian Gulf; and on the 13th Sir H. Leeke, commanding the naval forces, embarked for the same destination. On the 26th the whole fleet, consisting of thirty-four sail, assembled at Kíshm; and on the 3d of December the island of Kharg was reoccupied; and on the 7th, the army, consisting of two brigades,—the first under Brigadier Stopford, C.B, and the second under Colonel Honner,—disembarked at Halíla Bay, twelve miles south-east of Abúshahr (*Bushire*), the 20th Bombay native infantry, and the 4th Bombay rifles, being the first regiments on shore. On the 9th the troops advanced to dislodge the enemy from their position near the fort of Rashahr (*Reshire*). A body of Arabs made a most determined resistance at an earthwork, and the action was not gained without loss. Brigadier Stopford, Colonel Malet of the 3d cavalry, and Lieutenants Utterson and Warren of the 20th Bombay native infantry, were killed; and Captain Wood of that regiment was wounded; and thirty-five inferior officers and men were killed or wounded. On the 10th, after a sharp cannonade of three hours, Abúshahr surrendered, and the British flag was hoisted on its walls at 5 P.M. of that day. Fifty-eight guns were taken, and several Persian officers of high rank were made prisoners. In the meantime, a reserve force, consisting of the 14th light dragoons, the 1st Sindh horse, the 4th troop of royal horse artillery, the 1st company of the 2d battalion of foot artillery, the 78th Highlanders, and the 23d and 26th regiments Bombay native infantry, and a light battalion of ten companies drawn from regiments not serving with the force, had been assembled at Bombay under General Outram, to whom the command of the whole army was given. The general and his staff sailed from Bombay on the morning of the 16th of January 1857; and the army was now formed into two divisions, of which General Stalker commanded the first, and Brigadier Havelock the second. The reserve reached Abushahr in the end of January; and on the 3d of February General Outram, with the 2d European light infantry, the 64th and 78th Highlanders, the 3d Bombay cavalry, the Púnah horse, the 4th Bombay rifles, and 20th native infantry, the 2d Bilúch battalion, and some guns, marched to dislodge the enemy from an intrenched camp at Burázjún, 48 miles from Abúshahr. On the 5th this position was occupied, after a slight outpost affair, in which Cornet Spens of the cavalry, and a few troopers, were wounded. A vast quantity of stores and ammunition were taken in the camp. On the night of the 7th General Outram commenced his return, after having first exploded 36,000 pounds of the enemy's powder, to ignite which the rifles, with shell bullets invented by General Jacob, were used. During the darkness of the night the enemy made a sharp attack on the English column while on the march, in which Captain Mackler and Lieutenant Greentree of the 64th were wounded, and a few men killed and wounded. General Outram met with a severe accident, his horse falling with him, and rolling over him. At daylight on the morning of the 8th, the enemy were seen drawn up in order of battle, with their right resting on the village of Khush-áb, numbering 6000 infantry and 2000 cavalry, with about 15 guns, under Shujá'au'l-Mulk, reputed the best officer in the Persian army. After a short but sharp action, this force was completely routed, and fled, leaving 700 men dead on the field, and two guns in the hands of the English. A regiment of Persian infantry was in this battle ridden over and cut to pieces by the 3d Bombay cavalry, whose commanding officer, Captain Forbes, was severely wounded. The English loss was altogether one officer and eighteen men killed, and four officers and sixty men wounded. General Outram regained his quarters at Abúshahr by midnight of the 9th. On the 26th of March, the general having organized a force for the capture of Muhammarah, a town at the confluence of the Kárún with the Shatu l 'Arab, where the Persians had thrown up strong batteries, and had stationed an army of 15,000 men, attacked the place, and captured it, with the loss of but ten men killed, and one officer and thirty men wounded. The loss of the enemy was very severe On the 29th of March General Outram despatched a light force to pursue the enemy to Awáz, a town about 100 miles distant up the Kárún. This force proceeded in the Comet, Planet, and Assyrian steamers, under Commander Rennie. On the 1st of April, the expedition came within sight of the Persian army near Awáz, but on the right bank of the river, the town being on the left. Although the Persians amounted to at least 10,000 men, and the English troops did not exceed 300, such was the terror General Outram's victories had inspired, that the instant the English advanced on Awáz the Persians deserted the place, and not long after, a shell falling near their general's tent, the whole army likewise took to flight. Then was seen the astonishing spectacle of five heavy masses of infantry, well supplied with artillery, and 2000 horse, among which were the picked men of the Bakhtiyárí tribes, reputed the best cavalry in Persia,—a complete army, in short,—retiring before a handful of Englishmen, less numerous than the wing of a single regiment. The vast stores of the Persians were destroyed or thrown open to the plundering Arabs; and the retreating enemy suffered dreadful distress ere they reached Shustar, 100 miles distant, where was their nearest depôt On the 4th of April the expedition returned to Muhammarah; and on the same day General Outram received the news of the treaty which had been concluded at Paris on the 4th of March preceding, between the English government and the Persian, as represented by Farrukh Khán, ambassador of the sháh. On the 9th of May, General Outram issued orders for the breaking up of the force under his command, and their return to India; and on the 15th General Havelock embarked with his staff for the scene of his more arduous labours and glorious death at Lakhnau.

Thus ended the Persian war; and so severe was the lesson taught during General Outram's brief campaign, that not even the disasters of the Indian revolt could induce the sháh to venture once more on a rupture with the English government. It is possible that a movement might have again taken place in the direction of Hírát; but in May 1858 the sháhzádah commanding in that quarter suffered a severe defeat from the Turkamán hordes, the greater part of his army being destroyed, and several of his guns taken. (D. B—N) (E. B. E.)

PERSIAN GULF, a large inland sea in the S. of Asia, forming an inlet of the Indian Ocean, and lying between 24. and 30. N. Lat., and between 48. and 57. E. Long. Its form is that of a curve, having the convex side to the S.W.; the northern and north-eastern shores being bounded by Persia, and the western and southern by Arabia. It is entered from the ocean by the strait of Ormuz; and its greatest length from N.W. to S.E. is about 560 miles; its breadth varies from 40 to 200, but it is on an average about 160; and its entire area is estimated at 70,000 square miles. There are several islands scattered about in this gulf, which have an aggregate area of 1400 square miles. The shores of the Persian Gulf are the most arid and barren that can possibly be imagined. They generally consist of extensive sandy expanses, with hardly a blade of grass to relieve the monotony of the view, and the glare of the sand in the sun. The climate of the gulf for five months of the year is extremely hot, almost intolerable; and the thermometer stands probably higher in these regions than in any other place we are acquainted with. The Persian shores of the gulf are skirted by a range of mountains about 3000 feet high, from 3 to 30 miles distant from the sea; and though there are numerous small indentations on both coasts, the only bay of any size is that of Es-Elwak, on the coast of Arabia. The navigation is dangerous, on account of the shoals and reefs with which it abounds, especially on the Arabian coast, where large vessels can hardly approach near the land. The only rivers of any size that fall into the gulf are the Euphrates and Tigris, which unite to form the Shat-el-Arab, a river which falls into the north-western extremity of the gulf, about 70 miles below Bussorah. The tides in the Persian Gulf are much lower than those in the Red Sea; owing partly probably to the influence of the great rivers Euphrates and Tigris, and partly to the

shape of the gulf. The prevailing wind in the gulf is from the N.W. during the greater part of the year; but in the months of November, December, and January southerly breezes blow with considerable regularity, especially in the strait of Ormuz. The currents on the outside of the strait generally follow the direction of the wind; but in the gulf there is one that sets westward along the Persian shore. The shores of the gulf abound in fish, which, along with dates, almost the only produce of the surrounding country, form the chief articles of food to the inhabitants. These are not, however, sufficient to supply the wants of the people, and food has to be imported. The most of the inhabitants derive their means of sustenance from the fisheries of the pearls, for which this gulf is so famous. On the banks near the island of Bahrein, on the Arabian coast, these are found in the most abundance; but they are obtained in greater or less quantities throughout the whole of the western and southern shores. During the month of June, when the weather is somewhat cool, the fishing is carried on in the shallow water along the coast; but it is only in the intense heat which prevails in July, August, and the beginning of September, that the Bahrein banks, where the water is much deeper, are frequented, the divers being much inconvenienced when the water is cold. In diving, they have their nostrils compressed with a small piece of horn, and their ears stuffed with wax, to keep out the water; and with a net for oysters attached to their waists, a rope which they hold, and a stone to aid their descent, they go down, and remain for about two minutes under the water, shaking the rope when they wish to be drawn up. In favourable weather they sometimes dive twelve or fifteen times in a day; and the work, though exhausting at the time, is not considered to be injurious to the constitution. The annual value of the fisheries at Bahrein alone has been estimated to be from L.200,000 to L.240,000, though some of the merchants state it at a much greater sum; and the value of the whole pearl trade of the gulf is about L.300,000. The number of boats at Bahrein, containing generally ten men each, is about 1500. The larger shells are preserved for the sake of their lining of mother-of-pearl; but the oysters are never used for food, even in a country of such scarcity.

The trade of the Persian Gulf, which seems to have been carried on so early as the time of Alexander, is very considerable; the port of Bussorah, on the Shat-el-Arab, and that of Bushire, on the Persian coast, being the principal inlets for the produce of India and the East into Turkey and Persia respectively. The scheme for the steam navigation of the Euphrates would, if successful, make this the principal route to India; but the route by the Red Sea and Egypt, as in ancient times, presents many advantages over the other. The Arabian shores of this sea were for a long time infested with pirates; but the Jawasimi, the most daring of these, have been reduced to order by two British expeditions from Bombay in 1809 and 1819. The principal islands in the gulf, besides Bahrein, Ormuz, and Kishm, which are described in separate articles, are,—Busheab, near the northern shore, containing about 40 square miles, with a small town and harbour; Kaes or Kenn, off the same shore, also containing a small town and harbour; and Karej or Kharrack, a lofty island, nearly surrounded with reefs. The whole of the shores of the Persian Gulf, though belonging partly to Persia, are inhabited by Arabs; who extend on the N. as far inland as the mountains. Nearly all this country is subject to the Imam of Muscat, who pays an annual rent to the Persian monarch.

PERSIUS FLACCUS, Aulus, a celebrated Roman satirist, was descended from an equestrian family of considerable eminence in the state, and was born at Volaterræ in Etruria, in 34 A.D. The little that we know respecting his personal history is chiefly derived from a slight sketch commonly but erroneously ascribed to Suetonius. He lost his father at an early age; and his mother, Fulvia Sisennia, removed to Rome, that her son might enjoy the best training which the imperial city could furnish. He studied first under the grammarian Rhemmius Palæmon, and the rhetorician Virginius Flavus; and when he reached his sixteenth year he was placed in the school of the Stoic philosopher Annæus Cornutus, to whom he became passionately attached, and from whom he imbibed those tenets by which his writings are characterized. No less indebted was his education to Pætus Thrasea, whose noble character tended to form his mind to virtuous habits. His admiration of the Satires of Lucilius is said to have first turned his attention to the study of poetry. His character was austere, his mode of life pure and blameless, and his affection for his friends strong and unbending. At his death in 62 A.D., he left a considerable property to his mother and sisters; and his books, which are said to have consisted of 700 volumes, he bequeathed to his friend Cornutus. The philosopher recommended to his mother that she should commit to the flames all his manuscripts except his Satires. These were accordingly preserved, and consist of one book, divided, according to some, into five Satires, and according to others, into six. These Satires are intended to expound and illustrate some favourite doctrines of the Stoics. In executing this purpose, the author is not careful to copy his incidents and examples from real life. Describing them according to an exaggerated representation in his own mind, he strains all his faculties, and employs every literary art, to make the picture correspond to his own ideal conception. Accordingly his sentences are condensed into the most pithy and concise forms; his allusions are at once short and suggestive; his passion, in its vehemence, often assumes the rugged and expressive shape of colloquialism; and his frequent use of dialogue throws a spirited and life-like effect over the whole. It would even seem that the edge of his satire, directed against the vices of Nero's reign, sometimes became so keen that it required to be concealed under obscure phrases. From this description of Persius' Satires we can easily see how Lucan, Quintilian, Martial, and others, who knew the history of the author's time, were charmed with their pungency, and how modern students and commentators who have not that knowledge are perplexed by their almost impenetrable obscurity. Persius was first printed at Rome by Ulrich Hahn about 1470. The best editions are that of Isaac Casaubon, 8vo, Paris, 1605, reprinted by Duebner, 8vo, Leipsic, 1839; that of Otto Jahn, 8vo, Leipsic, 1843; and that of Heinrich, 8vo, Leipsic, 1844. There are numerous English translations, both in prose and poetry. The best poetical versions are those of Dryden and Gifford. The latest prose translation is that which forms, along with translations of Juvenal, Sulpicia, and Lucilius, a volume of Bohn's "Classical Library."

PERSON, Personality. The word *person* (Latin *persona*, "a mask," derived, according to Gabius Bassus, in Aulus Gellius, v. 7, from *persono*, "to sound through"), from being originally applied to a player's mask, came to signify the individual wearing it. Again, as one individual is distinguished from another more by the internal character than by the external traits of his nature, the term suffered a further transference of meaning, in being used in a sense synonymous with *man*, who is an intelligent, free, and responsible being. Person in this sense is distinguished from *thing*. Deity, considered as a creative cause and governing intelligence distinct from the universe, is a *person*. *Personality* is the idea of a person carried to its highest degree of generality. The essence of personality is generally supposed by philosophers to reside in the will.

PERSONIFICATION, or Prosopopœia, is, in rhetoric and composition, a species of metaphor, in which the highest degree of energy is produced by representing inanimate objects as endued with life and action.

PERSPECTIVE.

Projection of Points.

Perspective, or *Perspective Drawing*, is the art of representing solid bodies by means of pictures traced upon a surface. This surface is usually, though not necessarily, flat, and is most commonly placed upright.

The principle of the art is very simple, being founded on the fact that light moves in straight lines. If a transparent plate were placed between the eye and the object to be represented, and if the various points at which the light passes through were noticed, these would indicate the form of the picture, and if proper colours were laid on these, would produce upon the eye nearly the same effect which the object did, and would be a perspective picture of that object.

Such a picture, however, though accurately drawn, and though coloured quite in accordance with nature, can never produce on the eye exactly the same effect which the object itself does. The adjustment of the eye to distinct vision is not the same in both; and, in truth, the light which comes from any point in the object is not a mere line, but a conical pencil, having the aperture of the pupil for its base. Hence, however skilfully finished, a picture is always recognised as such.

The various contrivances which were used for enabling the painter to mark off with precision the outlines of his subject, are almost entirely superseded by the new processes of photography. The well-known instrument, misnamed the *camera lucida*, was one of the most ingenious of these; and the most simple of them was to set up an open frame, across which a network of threads was stretched; by placing the eye behind this frame and observing through which mesh each part of the object is seen, an expert draughtsman could readily transfer the outlines to a sheet of paper, on which a similar network had been traced.

The art of drawing in perspective is useful to architects and engineers, by enabling them to make views of intended buildings or machines. The ordinary plans, sections, and elevations, which are needed for carrying out a piece of work, hardly enable us to realise the appearance which the structure will have when completed, and hence the importance, particularly in matters of taste, of having perspective representations.

PROJECTION OF POINTS.

Let PQRS (fig. 1), be the ground plan of an intended building, and suppose that we wish to have its projection upon a vertical plane standing on the line AB, the point of sight being at E. We have only to join E with each point of the structure, and ascertain where the lines cut the picture plane. Thus having joined EP, the point p at which this line cuts the plane on AB, is the representative of P.

When the point of sight can be marked on the same sheet of paper with the plan, the simple joining of P, Q, R, S, &c., with it gives the representative points; but this rarely happens, and some contrivance has to be made for obtaining these points without actually drawing the lines.

Having let fall EC, a normal to the picture plane from the point of sight, C is called the *centre of the picture*, and EC the distance of sight. Produce EC to meet PT drawn parallel to the line BA, then we have the proportion ET : EC : : PT : pC; so that if ET and TP were known, the distance Cp could be very easily found. Now ET and TP are the co-ordinates of the point P referred to axes passing through the point E; hence a very convenient arrangement. Measure off along ET and CB a series of equal parts, and from the points of section draw lines parallel to AB and ET and we have a network, by help of

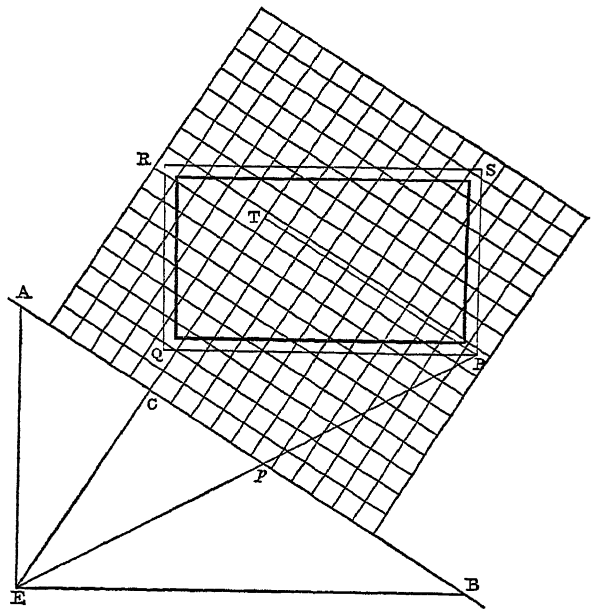

Fig. 1.

which the co-ordinates of the various points on the plan can be found.

This network may be drawn in pencil upon the working plans without injuring them; but, for those who are in the habit of making perspectives, it is convenient to have lines etched upon the surface of a plate of glass which can be laid down upon the plans in any required position.

In fig. 1, the distance of sight EC is ten of the actual divisions; calling it 100 and referring to the figure, we find ET=187, TP=104, whence 187 : 100 : : 104 : 55·6; so that Cp=55·6.

Again, referring to fig. 2, which is the elevation of our

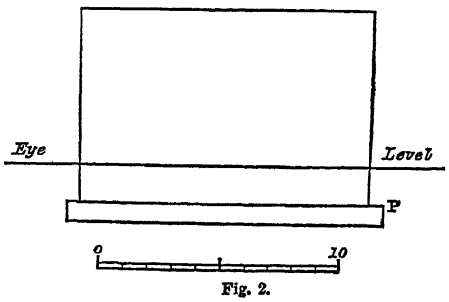

Fig. 2.

supposed building, we find the points P to be below the eye-level 16 and 24, whence the distances of their representatives below the eye-level on the picture must be 8·6 and 12·8, as found by the proportions 187 : 100 : : 16 : 8·6 and 187 : 100 : : 24 : 12·8.

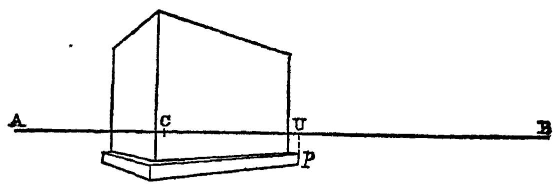

Fig. 3.

Let fig. 3 be the actual picture, C being the centre, and

Projection of Straight Lines.

CU the eye level; then the representation of the corner of the base at P is obtained by laying off CU=55·6 and Up, 8·6 and 12·8 respectively.

These calculations may be readily made by help of a sliding rule or of a circular logarithmic scale. The number 187 on the one slide being brought opposite to 100 on the other, we find opposite to the three numbers 104, 16, and 24, the three results 55·6, 8·6, and 12·8.

Denoting the co-ordinates of the various points of the structure by X, Y, Z; X being in the direction ET, Y in the direction TP, and Z in the vertical direction; and at the same time denoting by y and z the co-ordinates of the projections on the picture plane, reckoning from the point C, we have

$$y=EC\frac{Y}{X};\ z=EC\frac{Z}{X}.$$

Similar operations give the projections of the other points of the structure, and the whole details may be recorded in a tabular form as under:—

Point.	X	Y	Z	y	z
At P Base	187	+104	−16	+55·6	−8·6
			−24		−12·8
Wall	188	+96	−16	+51·1	−8·5
			+64		+34·1
At Q Base	117	−6	−16	−5·1	−13·7
			−24		−20·5
Wall	125	−5	−16	−4·0	−12·8
			+64		+51·2
At R Base	183	−48	−16	−26·2	−8·7
			−24		−13·1
Wall	182	−40	−16	−22.0	−8·8
			+64		+35·2
At S Base	253	+62	−16	+24·5	−6·3
Vanishing point B				+157·1	0·0
Vanishing point A				−63·6	0·0

The positions of the points on the picture are most readily marked by help of a graduated T square and drawing-board; the scale for the y being marked off along the edge AB (fig. 4) of the drawing-board, and that for the z along the edge CD of the square; and pieces with verniers may be fitted to slide on the blade of the square so as to give a great degree of precision. It is to be observed, that the scale used for the drawing need not be the same as that used for the plans and elevation, but may be made larger or smaller, according to the nature of the case—the distance of sight being increased or diminished in the same ratio.

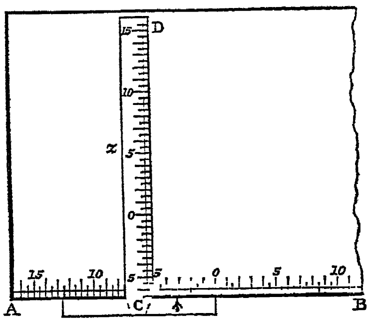

Fig. 4.

PROJECTION OF STRAIGHT LINES.

The projection of a straight line is also straight; for all the lines drawn from the eye to points in a straight line lie in one plane, and the intersection of this plane with the picture is a straight line; wherefore, if the projections of two points in a straight line be found, the projection of that line is known.

If we draw through the point of sight E (fig. 1) a line EB parallel to PQ, and meeting the picture plane in B, this line is in the plane EPQ, and therefore B is in the projection of QP upon the picture. Hence the projection of the line RS, and, in general of any line parallel to QP, must also pass through B. This point B is called the vanishing point for lines parallel to QP. Similarly, the vanishing-point for lines parallel to QR is found by drawing EA parallel to QR. Having then measured off on the actual picture (fig. 3). CB and CA equal to CB, CA, of fig. 1, we perceive that the face and end lines of the structure tend respectively to B and A.

The positions of the vanishing-points can be easily computed, since we have

$$EC : CB :: X_P - X_Q : Y_P - Y_Q \text{ and}$$
$$EC : CA :: X_R - X_Q : Y_R - Y_Q,$$

or in our example

$$70 : 110 :: 100 : 157·1 = CB$$
$$66 : -42 :: 100 : -63·6 = CA,$$

and when the angle PQR is right it is clear that the distance of sight EC is a mean proportional between the distances CB and CA of the two vanishing-points.

The determination of the points A and B facilitates greatly the delineation of the picture, since all the lines of the cornices, doors, and windows tend toward them. In no properly arranged drawing can both of these points be found within the limits of the paper, and therefore we must either support a pin at the proper place by a cumbrous erection, or make use of some instrument for drawing lines to a distant point. The *centrolinead*, contrived by the late Mr David Dick is, perhaps, the most convenient for the

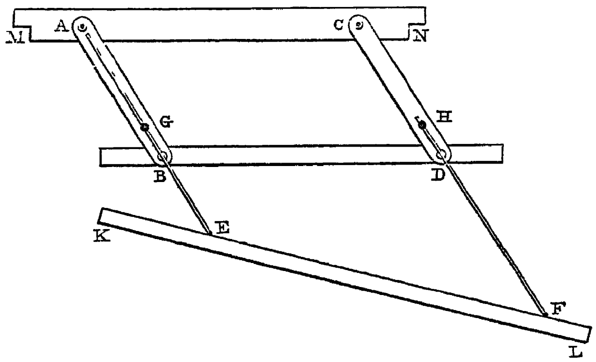

Fig. 5.

perspective draughtsman: it consists of a parallel ruler of the ordinary rhomboidal form, on the cross-ties, AB and CD (fig. 5) of which two pieces, BE and DF, are made to slide; these are retained in their places by pinching-screws at G and H. From the ends of the sliding-pieces two thin angular bits of steel project downwards to the paper, and against these a tracing-rule KL is laid. The edges of the steel at E and F must be accurately in the straight line passing through the pins of the parallel ruler. In order to facilitate the application of this instrument, notches are cut in the principal bar at M and N, exactly in the line of the joints. If, now, MN be applied to one of two converging lines, and the bar MN be secured against moving, by means of weights; and if, while the edge of KL is applied to the second line, the sliding-pieces at E and F be adjusted to bear upon it, the instrument is ready to trace lines tending to the same point.

The vanishing-points for all horizontal lines are found in the eye-level; but for lines which are inclined to the horizon, the vanishing-points are above or below that level. If, for example, there were a pediment on the face PQ of our supposed building, the vanishing-points for the cornices of that pediment would be found in a vertical line drawn through the point B of fig. 3, and at distances equal to the height of a pediment of which EB of fig. 1 is the half-breadth. Thus in Greek buildings the rise is about one-fourth part of the horizontal distance, in which case the positions of the vanishing-points will be found by laying one-fourth part of EB, fig. 1, above and below B of fig. 3.

When a row of equidistant vertical lines is put in perspective, the distances and the lengths of the projections are in harmonic progression; and if any two of these projections be given, all the rest can readily be found.

Let, for example, Pp and Qq (fig. 6) be the perspective representations of two equal vertical lines, and let it be proposed to continue the series either way.

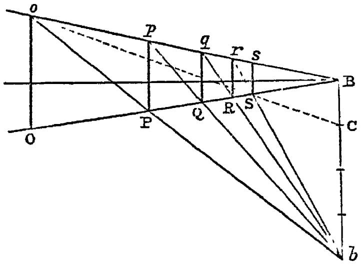

Fig. 6.

Join PQ, pq, and produce the lines till they meet in B; B is the vanishing-point for horizontal lines in the plane of the series, and a horizontal line drawn through B must be the eye-level. Join now pQ, and produce it to meet a vertical line drawn through B; the point of intersection b must be the vanishing-point for all the lines connecting the top of one upright with the bottom of the next; so that the intersection R of qb with BP marks the position of the perspective projection of the next upright, and so that the intersection o of bP with Bp gives the position of the next on the other side.

Again Oo and Ss being the projections of two uprights in a series, let it be proposed to divide the interval between them as into four equal parts. Having found the vanishing-point B as before, draw the vertical line through B, produce oS to meet it in C, and measure off Bb equal to four times BC, then b is the vanishing-point for diagonals of single intervals. The rest of the construction is obvious.

PROJECTION OF CURVED LINES.

Generally speaking, the most convenient method of drawing the perspective representation of a curved line is, to assume a number of points in the curve, to project these separately, and then to trace, by hand, a curve through the several projections. This process is applicable, whether the line to be projected be a fanciful curve sketched merely to please the eye, or a curve of a definite character. In the latter case, however, it is more satisfactory to determine strictly the nature of the projection.

The lines which join the point of sight with the various points in the given curve, trace out a conical or conoidal surface; and the intersection of the picture plane with that surface is the projection sought for; so that this branch of perspective drawing belongs essentially to the doctrine of conic sections.

When the proposed line is a circle, or any other line of the second order, the conoidal surface belongs to a cone proper, right, or oblique, as the case may be. Now the section of such a cone by a plane is also a line of the second order; wherefore the perspective projections of *circles*, *ellipses*, *parabolas*, and *hyperbolas* belong to the same class.

As the circle occurs in all machinery, and very frequently in buildings, the projection of the circle is a matter of special interest, and a ready means of obtaining it is a desideratum.

When five points in a line of the second order are known, the whole line is determined, and can be easily traced out by the method of radiants. If, then, we project five points in a circle, we can obtain its perspective representation. But as this process resolves itself into finding a number of points in the curve, and then tracing, by hand, a line through them, it is not preferable in practice to the simple process of assuming a number of points in the circle, and projecting these directly.

When the circle to be projected lies entirely on one side of a plane passing through the point of sight and parallel to the picture plane, its projection is a closed curve, generally elliptical, and sometimes, though very rarely, circular. Now, we can trace ellipses by help of mechanical contrivances, called *elliptographs*. These instruments can be readily applied when the major and minor axes of the curve are known; and therefore the practical problem becomes this, "To find the major and minor axes of the ellipse."

If the plane of the circle be parallel to the picture plane the projection is circular, and the centre of the projection is the projection of the centre. Otherwise, let the plane of the circle be produced to intersect the picture plane along the line PQ (fig. 7); this line may happen to be vertical, horizontal, or inclined.

From O, the centre of the circle, let fall OR perpendicular to PQ, and circumscribe the circle by the square KLMN, touching at S, U, T, and V.

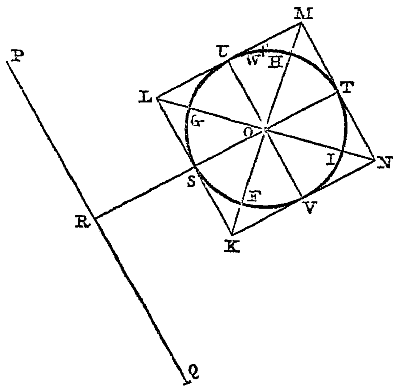

Fig. 7.

From the centre of the picture also draw CQ perpendicular to PQ, and suppose that the inclination of the two planes is represented by i.

Since the two lines LK and MN are parallel to the picture plane, their projections must be parallel to each other, and to the line PQ; let lk, mn (fig. 8) be these projections. The vanishing-point for the parallels LM, RSOT, and KN must be in the continuation of QC as at B. Since O is the intersection of the lines LN and MK, its projection must be at the meeting of the two lines ln and mk on the picture.

Having drawn through B a line parallel to PQ, produce

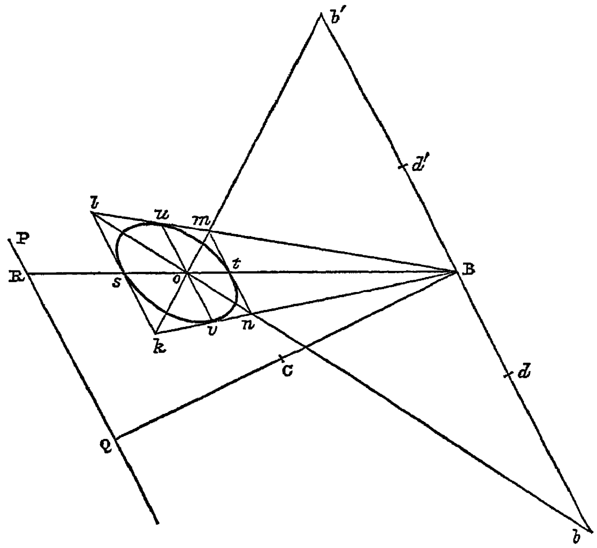

Fig. 8.

ln to meet it in b; b is the vanishing-point for all lines parallel to LN. Now we have, in general, $NK : KL :: EB : Bb$, wherefore, in this case, Bb must be equal to EB; but EB is parallel to the plane of the circle, so that $EB : BC :: R : \cos i$, or $Bb = BC \,.\, \text{ses}\, i$. But $BC = EC \cot i$; wherefore, since $\cot i \,.\, \sec i = \text{cse}\, i$, $Bb = EC \,\text{cse}\, i$. The vanishing-points for lines parallel to KM is at b', as far on the other side of B.

If we join V with F, the middle of the arc VS, the angle KVF is $22\frac{1}{2}°$, and the vanishing-point for lines parallel to

Curved Surfaces.

VF, as SI, GT, UH, is found by making Bd equal to the tangent of $22\frac{1}{2}°$ for Bb as a radius; while, by laying off an equal distance Bd', we obtain the vanishing-point for the lines VI, TF, SH, UG. By help of one of these we readily find the points f, g, h, i, and, by help of the other, we can check the accuracy of the work. (The letters f, g, h, i, are, for the sake of clearness, omitted in the figure.) Observing that the tangents at f and h tend to b, those at g and i to b', we obtain an octagon circumscribing the desired ellipse, after which an ordinarily expert draughtsman can trace it out.

All this supposes that the vanishing-points are within the range of the paper, or implies the use and frequent re-adjustment of the centrolinead. Those who possess an elliptograph would naturally prefer to determine the major and minor axes of the ellipse, so as to be able to apply the instrument. These axes can be obtained by means of the doctrine of conic sections, but the processes, whether geometrical or algebraic, are so tedious that the method of points is to be preferred in practice.

When the circumference of the circle is graduated, as in the case of arches or of toothed wheels, the projection by successive points is unavoidable.

Retaining the ordinates X in their former position, let us, for the sake of convenience, place the Y in the direction QC, the Z in the direction QP, the origin being still at the point of sight. Having assumed any point W in the circumference of the circle, let us denote the angle UOW by a, the radius of the circle being r, then the co-ordinates of the point W are,—

$$X_W = X_O + r \sin i \,.\, \sin a$$
$$Y_W = Y_O + r \cos i \,.\, \sin a$$
$$Z_W = Z_O + r \cos a,$$

so that the co-ordinates of its projection on the picture plane are,—

$$y_W = EC \,.\, \frac{Y_O + r \cos i \,.\, \sin a}{X_O + r \sin i \,.\, \sin a}$$
$$z_W = EC \,.\, \frac{Z_O + r \cos a}{X_O + r \sin i \,.\, \sin a}.$$

By giving to a the values corresponding to the various divisions of the circle, we can compute, by means of these formulæ, their several projections.

When the perspective of any other curve is wanted, the best method is to assume points in the proposed curve, and to find the perspective representations of these separately.

CURVED SURFACES.

The representation of a curved surface in perspective is a matter of considerable difficulty. When the surface is so placed that lines can be drawn from the point of sight to touch it, these lines form the surface of an enveloping conoid, and the intersection of the picture plane with this conoidal surface is the boundary of the perspective representation; but it is also the representation of the line in which the conoid touches the proposed surface, and, without the help of shading or colouring, the eye cannot distinguish whether the trace be meant to represent the line of contact, or the curved surface.

For example, lines drawn from the point of sight to touch a sphere lie in the surface of a right cone touching the sphere along a circle. The intersection of this cone with the picture plane is an ellipse, which is, indifferently, the projection of the sphere, or of the circle of contact. Nay, it might have been intended to represent any other curved surface enveloped by the same cone. The mere line then cannot convey the desired impression to the eye.

If the equation of the curved surface be represented by the symbol U=0, U being a function of the three ordinates X, Y and Z, we must also have $\delta U = 0$, or

Curved Surfaces.

$$\left(\frac{\delta U}{\delta X}\right)\delta X + \left(\frac{\delta U}{\delta Y}\right)\delta Y + \left(\frac{\delta U}{\delta Z}\right)\delta Z = 0;$$

so that the equation of a plane touching the surface at the point of which the ordinates are X′, Y′, Z′, must be

$$\left(\frac{\delta U'}{\delta X}\right)(X - X') + \left(\frac{\delta U'}{\delta Y}\right)(Y - Y') + \left(\frac{\delta U'}{\delta Z}\right)(Z - Z') = 0.$$

If this plane pass through the point of sight, the point at which it touches the curved surface is in the line of contact, so that the character of this line is determined by the two equations

$$U' = 0, \text{ and } \left(\frac{\delta U'}{\delta X}\right)X' + \left(\frac{\delta U'}{\delta Y}\right)Y' + \left(\frac{\delta U'}{\delta Z}\right)Z' = 0.$$

If now x be the distance of sight, y and z the co-ordinates of the perspective limit, we have

$$xY' = X'y\,;\ xZ' = X'z,$$

and on eliminating X′, Y′ and Z′ from these four equations, we obtain an equation in y and z, which determines the form of the perspective outline.

The equation of a sphere, of which the centre is O and the radius r is

$$(X - X_O)^2 + (Y - Y_O)^2 + (Z - Z_O)^2 - r^2 = 0, \quad . \ (1.)$$

which corresponds to the general equation U=0. Treating this by the method of partial differentials, we obtain, on halving,

$$(X - X_O)X + (Y - Y_O)Y + (Z - Z_O)Z = 0, \quad . \ . \ (2.)$$

and this subtracted from the preceding equation, leaves

$$XX_O + YY_O + ZZ_O = X_O^2 + Y_O^2 + Z_O^2 - r^2, \quad . \ . \ (3.)$$

which is the equation of a plane perpendicular to the line joining E with O; the intersection of this plane with the surface of the sphere gives the line of contact. By adding the double of equation (3.) to (1.), we obtain

$$X^2 + Y^2 + Z^2 = X_O^2 + Y_O^2 + Z_O^2 - r^2, \quad . \ (4.)$$

which belongs to a sphere having its centre at the origin, and its radius the side of a right-angled triangle, having the distance EO for its hypothenuse, and r for its other side. The equation of the ellipse may be now found by eliminating from (3.) and (4.), the quantities X, Y, Z, by means of the equations

$$xY = Xy\,;\ xZ = Xz,$$

the result being

$$(x^2 + y^2 + z^2)(X_O^2 + Y_O^2 + Z_O^2 - r^2) = (X_O x + Y_O y + Z_O z)^2,$$

which indicates a line of the second order, the major axis of which passes through the centre of the picture.

From this example of the application of the general method to a very simple case, it will be seen that the strict analytic process is far too laborious to be used in projecting the curved surfaces which are found on buildings or in machinery: a process readier, though perhaps not so satisfactory, is needed by the practical draughtsman.

It is of no use to assume, at random, points upon the proposed surface, since the projections of these would not give the limiting line of the picture. We must endeavour to select points on the line of contact.

A convenient though, in some cases, rather a tedious process, is to make a series of sections of the proposed surface, to project these, and then to draw a line touching and inclosing the projections. In the case of a cylinder or of a truncated cone, it is enough to project the two ends and to draw straight lines touching the two ellipses, while for a pointed cone, tangents drawn from the projection of the

Inverse Problem.

apex to the ellipse which represents the base, are the limits of the picture.

For an annular surface, as that of the torus of a column, it is convenient to take sections made by planes passing along the axis of the solid, as these give equal curves; and it may be remarked in general, that only a small part of each curve need be projected.

INVERSE PROBLEM.

When a drawing, purporting to be the perspective representation of an object is presented to us, we endeavour to realize the form of that object. This we can only do strictly, by resolving the problem "of what object can such a drawing be the true picture?" Shading and colouring aside, the lines of the picture may be the projections of an infinity of diverse solids, the corners and edges of which are in the straight lines joining the eye with the various traces; and these again change with every alteration in the position of the spectator. Hence the inverse problem is incapable of a strict solution.

A correct drawing of any familiar object, though in outline only, at once suggests the idea of the object which it was intended to represent; and though it cannot be demonstrated strictly to be the picture of such and such a thing, the mind, through the force of association, is satisfied of the fact. Adding to the actual delineation the knowledge that the picture is meant to represent, say a house, we may, to a certain degree, thence determine the proportions of the structure.

Let us suppose, for example, that fig. 9 is placed before

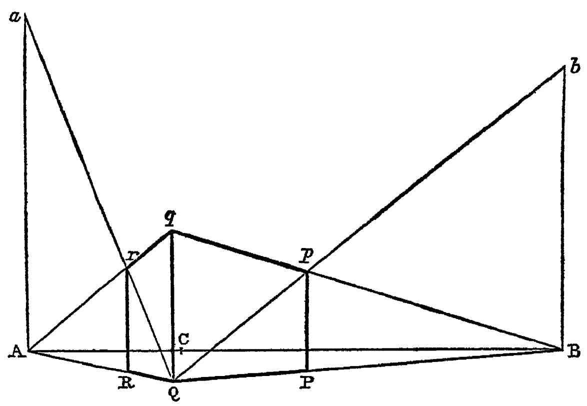

Fig. 9.

us. We recognise that it is intended to pourtray the block of a building, and infer that the building is rectangular. Query, with this inference can we deduce the actual proportions of the structure from its picture in perspective?

The first thing to be discovered is the position of the point of sight. Having produced QP, qp to meet in B, QR, qr to meet in A, we obtain the two principal vanishing points, and having joined AB we have the level of the eye. If the picture plane have been placed upright, and if the drawing have been accurately made, the lines Rr, Qq, Pp, are perpendicular to AB. The point of sight E must be in a plane perpendicular to the plane of the paper, and meeting it along the line AB. Now, the line EA is parallel to the lines represented by QR, qr; EB to those represented by QP, qp; wherefore the angle AEB must be right, and the point of sight must be found somewhere in the circumference of a semicircle described on AB as a diameter; but we have no positive means of determining at what point in that semi-circumference the eye ought to be placed. However, it is customary to place ourselves right in front of a picture, so that if we take C, the middle of that portion of the eye-level which is included within the limits of the paper, we may assume it as the middle of the picture. Erecting then at C a normal to the picture-plane, equal to a mean proportional between CA and CB, we obtain the position of the point of sight, and thus we can construct the part ABCE of fig. 1.

Binocular Perspective.

In order to discover the proportions of the parts of the building, draw the diagonals Qp, Qr on the picture, and produce them to meet vertical lines drawn through the vanishing points B and A, then, since the line joining the eye with b is parallel to that represented by Qp, we have the proportion EB : Bb : : length represented by QP : length represented by Pp, and thus we obtain the ratio of the length to the height of the building. Similarly EA : Aa : : breadth : height.

The ground-plan of the building may be reproduced by measuring from C, in fig. 1, a horizontal distance CP, taken from the picture, joining Ep, and producing it to any supposed distance pP. A line drawn through P, parallel to BE, is the line of the front, and the length of it may be found by measuring off Cq equal to the horizontal distance on the picture, by joining Eq, and producing it to meet the line of the front.

From these examples it is easy to see how the whole details of the structure could be scrutinized, if it ever should happen that the actual dimensions had to be obtained from a perspective drawing. It is evident that these operations cannot give the actual dimensions: some object of a known magnitude must form part of the picture, so as to be a standard of comparison.

Unless a picture be viewed from its proper point of sight, the impression produced must be different from that intended by the artist. In landscape and figure paintings the effect of a misplacement of the eye is not very conspicuous, but in drawings of buildings and machinery it is painfully felt. When the picture of a house is viewed from beyond the point of sight, that corner which is towards the eye appears acute; it seems, in fact, equal to the angle of two straight lines joining the eye with the vanishing-points A and B; and conversely, if the spectator come too close to the picture, the corner appears to be obtuse. By changing slowly one's distance from a perspective drawing, and studying the effect of the change, the proper distance may be passably well ascertained.

On moving the eye across the picture, the faces of the building, seeming always to be parallel to the lines joining the eye with the vanishing-points, appear to change their directions, as if the whole structure turned to follow the observer. This effect is well known in the case of portraits in which the model has been looking at the painter; the eyes of such portraits seem to follow the spectator wherever he may go.

In preparing vignettes and frontispieces, it is very common for engravers to reduce some well executed drawing; the effect of this is to reduce also the distance of sight, and to bring it far within the limits of distinct vision. The eye cannot be placed nearer the paper than twelve or ten inches, while distance of sight for vignettes is reduced often to three or four inches, sometimes even to less. Hence a painful and even ludicrous distortion: if there be buildings, they look as if sharpened at the corners to angles of 50, 40, or 20 degrees; and if it be a landscape, the retirement of the distant objects is out of all proportion to the breadth of the foreground.

BINOCULAR PERSPECTIVE.

We cannot realize the meaning of a perspective drawing without the aid of the association of ideas; but if we had two drawings of the same object as seen from two known separate points of view, we could thence deduce strictly the dimensions and form of the object represented by them. The distance between the two points of sight would form

the base of a triangulation, and the problem would become a case in trigonometry.

Actually the appearances presented to the two eyes are two such pictures, and the convergence which we find it necessary to give to the two optical axes in order to bring the images of a given point to coincide, enables us to estimate the nearness of that point. Of this we have a beautiful example in the habits of the chameleon. The eyes of that lizard are set upon two projecting balls which turn freely in their sockets, and their motions are quite independent of each other, so that while the one eye may be intently watching some insect, the other may be moving about in search of a more convenient prey. The field of view is very small, and hence an incessant motion of exploration. As soon as the animal has perceived a fly tolerably within range, he brings both eyes to bear upon it, and advances cautiously till it be within the reach of his long tongue: he never mistakes the distance; single vision does not enable him to estimate it with sufficient nicety, but the convergence of the two eyes does so.

Professor Wheatstone showed, many years ago, that if two properly projected drawings be presented, one to each eye, the effect of the double vision is to give the appearance of solidity. The only thing which hindered Wheatstone's stereoscope from at once becoming a valuable addition to our stock of illustrative apparatus was the extreme difficulty of making the drawings sufficiently exact. Only simple geometrical forms could be attempted, and the invention had almost been forgotten. But the recent discovery of photography, by enabling us to obtain minutely exact views of actual objects, has invested the doctrine of binocular perspective with new importance.

The projection of twin drawings for the stereoscope differs in no respect from the processes of ordinary perspective; the only thing to be attended to is the choice of the points of sight. If we were to make two pictures of a large building as seen from points only $2\frac{1}{2}$ inches apart, the differences between them would be almost imperceptible; in the language of the surveyor, the base would be far too short. Hence we are obliged to separate considerably the points of sight; but when we come to unite the two pictures, we see them from the eyes, which are $2\frac{1}{2}$ inches separate, and hence the impression is not that of a large building but of a small model. In other words, the stereoscope is applicable to objects at hand, and can only give diminutive views of remote objects.

The accompanying figures (fig. 10) are the projections of a rhomboidal solid, with one of its diagonals drawn. When

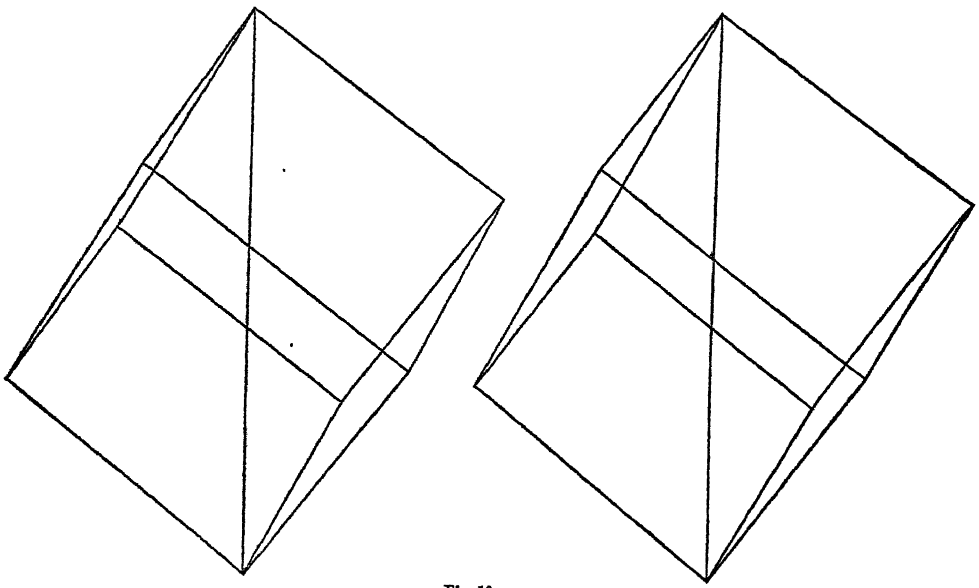

Fig. 10.

viewed through any of the ordinary stereoscopes, the illusion is complete; but if the wood engraver had attempted to draw the other three diagonals, they would have been seen, in all probability, to have passed each other at the middle, as any one may convince himself by drawing them in pencil; the reason is, that the slightest deviation from the proper place occasions a great change in the apparent position of the line; and hence the great difficulty of making stereoscopic engravings, or even of touching up by hand photographic pictures.

It must be observed, that a pair of stereoscopic views can never produce on the eyes exactly the same effect which the sight of the object would; for when we look from one part of an object to another, the adjustment of the focal length, as well as the convergence of the axes, is changed, and these two, from habit, are inseparably connected. Now, it is only the convergence of the eyes which is accommodated in the arrangement of binocular drawings, so that the use of the stereoscope must always do violence to the natural association of the muscular efforts. (E. S.)

PERTH, the principal town of Perthshire, and the most central in Scotland, is situated on the banks of the river Tay, about 25 miles above its confluence with the German Ocean, in Lat. 56. 23. 40. N., and Long. 3. 26. 20. W. The city, eminent for the beauty of its situation, occupies the centre of an amphitheatre, varied, pleasing, and highly picturesque. Encircled by richly wooded and highly cultivated heights, sloping more or less proximately, sits embedded the "Fair City," with its splendid and spacious parks, the Inches, extending their swardy expanses north and south, and its noble river flowing through its apparent confines.

From the rising grounds by which the city is surrounded, although none of them is of great altitude, some of the finest views in Scotland are to be obtained. Those from the summit of Moncrieff and Kinnoull Hills are of great extent, beauty, and variety. The prospect from Moncrieff Hill, described by Pennant as "the glory of Scotland," embraces on the west and south the vale of Strathearn; on the east

the curve of the Tay to the ocean; and in the distant north a noble sweep of the Grampian Mountains, with much of the Alpine scenery of Perthshire and contiguous counties. From Kinnoull Hill the view is less extensive, but scarcely inferior in beauty, variety, and interest. The height of Moncrieff Hill is 756 feet, and the height of Kinnoull Hill is 632 feet above the river.

The site of the town is only a few feet above the level of the sea; and hence it is exposed to partial inundation when the Tay is very much flooded. The height of the low grounds along the bank of the river varies from only 20 to 30 feet above the mean level of the sea; and the plain on which the town is built is still lower. Inconveniences of this kind of much consequence, however, are of rare occurrence.[1] Although lying low, the town is not by any means to be regarded as unhealthy; and though it is also closely surrounded by hills on all sides except towards the north, yet these being of moderate elevation, the hygrometric state of the incumbent atmosphere is little affected by their vicinity, and the air is accordingly more dry and clear than might have been expected. Fogs are not more frequent than in the open plains; and the diseases resulting from a damp soil and a humid atmosphere are of rare occurrence, or rather altogether unknown. The gravelly and sandy subsoil of the district, and the perpetual change of air occasioned by the current of the river in all states of the weather, contribute to render the climate of Perth more salubrious than that of many towns possessing a greater elevation. The mean hygrometric state of the air at Perth (as was ascertained, a good many years ago, by the late Professor Anderson) appears to be when the atmosphere is charged with about four-fifths of the entire quantity of moisture it is capable of holding in solution at the mean temperature. The hygrometrical means for 1857 were—mean of dry-bulb, 50°·6; mean of wet bulb, 45°·9. The quantity of rain observed to fall in the immediate neighbourhood of the town seems to correspond pretty nearly with the mean quantity for the latitude. In the year 1857 the fall was 30·464 inches, and the number of days in which it fell 164; so that against the number of wet or snowy days there were 201 fair days. The mean annual fall of rain, deduced from a period of six years—viz., from the year 1852 to 1857—was 30·30 inches. The mean height of the barometer, reduced to 32° for 1857, was 29·85 inches. The mean annual height, deduced from the same period of six years, as above in the case of the rain, was 29·67 inches. The mean temperature of 1857 was 51°·1, and the annual mean deduced from the above period of six years, 46°·5. The following are the observations of the wind for the year 1857, viz.:—N., 16 days; N.E., 21; E., 14; S.E., $59\frac{1}{2}$; S., $15\frac{1}{2}$; S.W., 63; W., $62\frac{1}{2}$; N.W., $20\frac{1}{2}$; calm, 93 days; mean force of the wind, $\frac{0\ 6}{0\ 38}$. The mortality tables for the years 1855, 1856, and 1857, show respectively somewhat under $2\frac{1}{2}$, 2, and 3 per cent. deaths to the population. The deaths registered in the burgh, exclusive of Kinnoull, in 1855, were 577; in 1856, 490; and in 1857, 695,—being for 1855, 1 in 41; for 1856, 1 in 48; and for 1857, 1 in 34 of the population. For the whole burgh, the births registered in 1857 were, 390 males and 370 females; and the marriages 237.

The greater part of the parish of Perth rests upon the old red sandstone formation, which stretches through the valleys of Strathmore and Strathearn. It contains altogether about 3400 imperial acres, and exhibits much diversity of soil. As regards the town and its suburbs, considerable changes in respect of soil and elevation must from time to time have taken place, as abundant evidence exists, low as it still is, of its having, at one time, been very much lower. Excavations in all parts of the town are constantly exposing the remains of buildings and numerous other traces of a lower level.

Perth is one of the most ancient towns in Scotland, and its civil history, up to the sixteenth century, is deeply interwoven with the national annals. Its origin is buried in the obscurity of the past, and the very etymology of its name is uncertain. The latter is now generally supposed to be of Celtic origin—an opinion which receives considerable support from the analogy of names of other places in the same neighbourhood, as well as all over Scotland, clearly of Celtic derivation. Perth must have been a place of considerable note long before the period when existing history refers to it. The "House of the Green" stood on what for ages had been reckoned the site of an old British temple, which, on the authority of Geoffrey, who wrote his history in the beginning of the twelfth century, was believed at the time of Hollinshed to have been built by the son of Regan, second daughter of Lear, who governed Britain long before the birth of our Saviour. This tradition is so far supported by the fact, that in digging many years ago for a proper foundation for the house which now occupies the site, subterranean buildings were discovered answering the description of such structures. It is a generally received opinion, that Perth was built and fortified by Agricola, who erected a citadel to maintain his conquests, and check the wild spirit of the savage natives. In corroboration of this opinion, it may be stated that there are no fewer than four military or Roman roads from different quarters, all leading to, if not centering in, Perth. The town was early known by the name of St Johnstoun, from the inhabitants, after their conversion to Christianity, having consecrated the church and bridge to John the Baptist, and having made him tutelary saint of the town. But there is no public document in which it is so designated, although the common seal of the burgh, which was in use in the year 1400, and of which many impressions are still in existence, represented the martyrdom of St John, and bore the legend, "S. communitatis ville Sancti Johannis Baptiste de Perth."

That Perth was a burgh in the reign of Edgar, 1106, appears from a charter then granted to a John Burgess, in which he was designated a burgess of Perth. The charter of confirmation by James VI. makes particular mention of one which had been granted by David I., who died 1153. King David's charter was renewed and confirmed by that of William the Lion, which is extant. From this point the authentic history of Perth may be said to begin. It enjoys the dignity of having been the ancient capital of Scotland. James II. was the first Scottish monarch crowned in Edinburgh, an event which happened in the year 1447. Soon thereafter the Parliament and courts of justice were removed thither; but it was not till 1482, in the reign of James III., that Edinburgh was declared to be the capital of Scotland. There seems good reason to believe, that when Edward I. ransacked the chartulary of Scone,

[1] The most remarkable inundations of which we have any record occurred in 1210, 1621, 1740, 1773, and 1814. The greatest of these appears to have been the first; in which, says Fordun in his *Scotichronicon*, "King William, his son Prince Alexander, and the Earl of Huntingdon, the king's brother, left the town in a small boat, and reached the dry land in safety. A few of the nobles who happened then to be at court accompanied them in other boats; others on the tops of houses, along with the townspeople of both sexes, with difficulty escaped a watery grave. . . . The river rose to such a height, that not boats merely, but large vessels, could be impelled along the streets and broadways without any difficulty or impediment. . . . Not only several houses, but the bridge over the Tay and an old chapel, were overthrown by the waters." Of the flood of 1621 it is preserved in the kirk-session records,—"that therethrough the Brig of Tay was hailly dung doun, except only one bow thereof standing. None could get furth of it, nor yet cum within it to make any relief thereto." It appears, however, when at its very height, not to have been such as to have prevented the people repairing to church, for it is also recorded that "Mr John Malcolm, minister, powerfully endowed with God's Spirit, caused ring the preaching bell on Sunday at seven hours of the morning, and the haill inhabitants came to the kirk." Little is recorded of the inundation of 1740. That of 1775 was produced by the shutting up of the river by ice, and was the cause of much injury to property. Of a very similar character was the more recent flood of 1814. It attained the height of $23\frac{1}{2}$ feet, and caused much damage to property. Several families were removed from their houses by means of boats, and communication held with many others in the same way. The last considerable flood took place in October 1847, and was produced entirely by rain. The water on this occasion rose to within 2 feet of the height attained in 1814, and with serious injury to property, submerged all the lower lying parts of the town.

he also made free with the records and documents of public value preserved at Perth; hence the absence of, in a great measure, such papers, as were to have been expected in a city so prominent in the nation's history. The records of the burgh are, however, of very considerable antiquity, but unfortunately the oldest cannot now be deciphered. The earliest legible date is 1512. Cant, in his History, however, produces a full and uninterrupted list of magistrates from 1465 to 1765. From the ancient importance of the city, its annals are replete with incidents and events of more than local interest and consequence. In 1298, after the battle of Falkirk, Edward I. reduced all the fortresses in Scotland, but fortified Perth, and rebuilt the walls in the strongest manner. Such defences proved in these and subsequent times exceedingly necessary. In these rude ages it was surrounded by the feudal castles of several powerful barons, with some of whom the inhabitants appear to have been frequently at feud, whilst with others, as Chartres of Kinfauns, the Earl of Gowrie, the Earl of Atholl, Lord Scone, and Threipland of Fingask, they were on such friendly terms as to have had one of their number for chief magistrate. Amusing evidence is to be found in the records of the burgh, of these alternate feuds and fraternizations. The worthy burgesses seem to have been men of mettle in those days; and on various occasions, sallying forth from behind their walls, set fire to the castles of their haughty neighbours, when the latter, probably in reprisal for some offence, had forbidden their vassals to carry provisions to the city. In the year 1311, Robert Bruce laid siege to the town, but was obliged to withdraw his troops, after various unsuccessful attempts to take it. Not discouraged, however, the Scottish hero, having selected a band of determined men, and chosen a dark night, led them on in person, scaled the walls, and carried the town sword in hand; the king himself being the second man who entered the place. About the beginning of the fourteenth century, the famous combat between the Clan Chattan and the Clan Quhele or Clan Kay, took place on the North Inch, and was decided in favour of the former, partly by the bravery of a citizen or burgess called Harry Wynd, whom the chief of the Clan Chattan had engaged on the spot to supply the place of one of his men who had failed to appear This city has also been the scene of several of those social tragedies, in which the history of Scotland, in those rude times, was so prolific. In the year 1336, King Edward III. of England stabbed his brother the Duke of Cornwall, before the high altar of the church of St John; and in 1437, James I. was murdered in the monastery of Blackfriars, by Walter, Earl of Atholl, Robert Stewart, his lordship's grandson, and Robert Graham, their kinsman, with circumstances of the most savage barbarity. The murderers were executed in Perth, and the details of their punishment are of the most revolting character, reflecting but little honour on the good feeling and humanity of our forefathers. Perth appears to have been several times visited by the plague, particularly in 1512, 1585, 1608, and 1645. Its ravages during the last of these visitations were severe, 3000 persons having become its victims. In 1539, Margaret, queen of James IV. was interred in the Carthusian monastery, beside the tomb of James I. Her Majesty died at Methven Castle. In 1617, James VI. honoured the ancient capital of Scotland with a visit, the details of which, as found in the burgh records, are not a little graphic and entertaining. And in 1623, one of those exhibitions, of which James was so fond, and which leave a stain upon the national annals, took place in Perth; we mean, the burning of three poor women for witchcraft. In 1633, Charles I., in his tour through Scotland, visited Perth; and in 1651, Oliver Cromwell took military possession of the city, and erected a citadel on the South Inch. The year 1600 was rendered memorable by the occurrence of the famous Gowrie conspiracy; one of those events on which ingenuity and research have exhausted themselves, and which, in its origin and circumstances, still remains enveloped in impenetrable mystery.

In the ecclesiastical history of Scotland, Perth occupies a somewhat prominent position. Here, it may be said, the work of reformation in Scotland was commenced by Knox. In 1544, Cardinal Bethune having obtained an act in favour of the bishops and clergy to persecute and punish heretics, came to Perth, when an accusation was forthwith lodged against certain persons for interrupting a friar of the name of Spence while preaching. The accused were found guilty, and condemned, and on the following day were executed—four men being hanged; and one woman, whose offence was refusing to pray to the Virgin Mary, drowned. Other citizens were banished. Before the Cardinal left Perth, the Regent, at his instigation, turned Lord Ruthven, provost of the town, out of his office, and conferred it upon Chartres of Kinfauns. The citizens, however, resisted the attempt, and repulsed in a smart skirmish the Cardinal's nominee, who came to enter upon his duties at the head of an armed force. The means adopted here and elsewhere to suppress the dawning Reformation only served to spread it. Executions became general, and the people became more and more alienated from the Church. The public exercise of the reformed religion having been introduced into Perth, the regent queen commanded all the Protestant preachers to be summoned to a court of justice to be held at Stirling the 10th of May 1559. The people resolved to answer the summons along with their ministers, in such numbers as induced the queen to feign an abandonment of the trial. The people dispersed, and the preachers, with a few leaders, remained at Perth. The dissimulations of her Majesty ended, on the said 10th of May, in the banishment of the still refractory ministers; the day after which John Knox appeared in Perth, and preached the famous sermon against the idolatry of the Church of Rome, which proved indirectly the cause of the first great outbreak of the Reformation. The indiscretion of a priest, who, after the sermon, was preparing to celebrate mass, precipitated such of the congregation as remained into action with tumultuary but irresistible violence. They fell upon the churches, overturned the altars, defaced the pictures, broke in pieces the images, and proceeding next to the monasteries, in a few hours laid these sumptuous fabrics almost level with the ground. The fury of the mob, however, was in a great measure confined to the edifices; little personal insult was offered to any one, and not a single Roman Catholic was put to death. This riotous insurrection was in nowise the result of premeditation, was not joined by the more respectable citizens, and was publicly censured and condemned by the ministers and leaders of the Reformation. Her Majesty heard of the destruction of the religious houses at Perth with much concern, and determined to inflict the severest vengeance on the Reformers. Both parties took the field; negotiations ensued; Perth was thrown open to the queen, and occupied by a French garrison. But no sooner was peaceable admission gained, than all the previous stipulations were disregarded; the whole town was oppressed; swarms of priests were introduced into it; Lord Ruthven and the bailies were superseded in their offices; Chartres was made provost; and the exercise of no other religion than the Roman Catholic was permitted. Relief from the insolence and exactions of the garrison was only obtained after a regular siege by the Reformers. On the 26th of June Lord Ruthven attacked the town on the west, and Provost Halyburton of Dundee fired into it from the bridge, and speedily obliged the garrison to capitulate. From this resulted the destruction of the abbey and palace of Scone on the following day. After the loss of Perth, the Queen endeavoured to seize Stirling. Argyle, and Stewart, prior of St Andrews, having received intelligence of her design, marched out of Perth with three hundred citizens, resolved to prosecute the Reformation, or perish in the attempt. That their determination might be the more apparent, they, instead of ribbons, put ropes about their necks, intimating thereby that whoever of their number should desert their colours should be hanged by the ropes. Hence the origin of the proverb of "St Johnstoun's Ribbons." The people joined them everywhere as they proceeded; and before they reached Stirling, their numbers had increased to five thousand. The gates of Stirling, and of every other town in their way, were thrown open to receive them. They, without violence, took possession of Edinburgh, cast the images out of its churches, and placed in them ministers of the Reformation.

Perth has long since been divested of almost every relic of antiquity, although at one time few places were so highly favoured in this respect. Hardly a trace is left of any of the numerous religious houses with which it abounded. The Parliament House and Gowrie Palace are also entirely removed. Two small portions of the ancient city wall, however, are still preserved; but the *lade* is the only work which has passed entire from ancient to modern Perth.

Claiming to be first noticed among the public buildings of Perth is the old church of St John. It is altogether unknown when and by whom this edifice was founded; but from such historical facts as can now be gathered, it must have been built about the middle of the fifth century. Stones were requested by King Robert Bruce in 1329 for its repair from "our beloved and faithful religious men, the abbot and convent of Scone." In the year 1410, the edifice was in good repair; all the old altars had been removed, and new ones erected. At the period of the Reformation, it is described as in a very high state of repair, containing rich altar pieces, images, decorations, and ornaments. But the fabric is of such very remote origin, and has undergone so many repairs, that it is difficult to say what or whether any of the original building now remains. There can be no doubt, however, that the tower

and the pillars of the East and West churches are of very ancient date. When it was divided, as at present, into three places of worship, is not precisely known. That part of it which is now occupied as the West church must have been separated from the rest about the beginning of the seventeenth century, for it is recorded that a public meeting of the inhabitants was held in it in 1608. A variety of other public transactions are recorded as having taken place there. Prominent among them is the meeting of the General Assembly in August 1618, at which the famous Five Articles of Perth were passed. In 1716 it was fitted up as a place of worship; and in 1771 the eastern division, or choir, now the East church, was separated from the old or Middle church. The present fittings of the churches are all modern. One of the bells bears date 1400, and another 1506. The only other church possessing any particular interest is the South United Presbyterian church, having been erected in 1740 for Mr Wilson, one of the four original seceders from the Church of Scotland.

Of the other public buildings, the principal are the bridge over the Tay, completed in 1771, at an expense of L.26,631, of which government contributed L.11,000, the city of Perth L.2000, and the royal burghs L.500; the County Buildings, erected in 1819–20, at a cost of L.32,000; the General Prison; the military barracks, erected in 1793–4; the public seminaries, erected by public subscription in 1807, at a cost of about L.7000, of which the city contributed L.1050; Murray's Royal Lunatic Asylum, completed in 1827, and erected at an original cost of upwards of L.40,000, bequeathed by Mr James Murray, a native of the parish of Perth, to which considerable additions have been made by the directors, including two contiguous properties; the monument erected to the memory of Provost Marshall, in which are accommodated the Perth Library and the library and museum of the Literary and Antiquarian Society; the water reservoir, erected in 1830; the infirmary, erected in 1836, at a cost of L.6000; and the general railway station, partially erected in 1848, and still uncompleted. The only other building of much note is the hospital, founded by James VI. in 1569, and which has two royal charters.

Perth abounds in religious, educational, and charitable institutions. There are twenty-four churches, comprising six places of worship belonging to the Established, six to the Free, and three to the United Presbyterian Churches; in addition to these, there are Original Secession, Wesleyan, Independent, Baptist, English Episcopalian, Scotch Episcopalian, and Roman Catholic Churches; there is also a Glassite meeting-house. There are eighteen public schools, besides a considerable number of private schools; also three ragged or industrial schools. In eleven of the public schools education is afforded to the poorer classes at fees more or less small; and in one, under the management of the incorporated trades, to the sons of members gratuitously. The charitable institutions are no less abundant. The principal of these are the infirmary, which contains accommodation for 68 patients, and is maintained at an annual cost of about L.1300; the Indigent Old Men's Society, which expended in provisions and clothing, in 1857, L.165; the Indigent Old Women's Society, which similarly disbursed L.170; the Destitute Sick Society, L.52; and the Ladies' Clothing Society, L.28. Besides these, there are the Lethendy Mortifications, the annuities of which amounted in 1857 to L.723; and James VI.'s Hospital, affording outdoor relief to the extent of about L.600 per annum. The incorporated trades also devote a large proportion of their funds to the assistance of their poorer members. In this way, in 1857, the trades expended the sum of L.1062, and the guildry L.464. The poor's rates for the burgh amounted in 1857 to L.6543.

Of the trade of the place a very vague estimate only can be formed. The exports and imports by the river afford no index to it whatever, the great bulk of the traffic being carried on by railway. Perth cannot be said now, as in former times, to be famous for any particular manufacture or branch of business. Cotton goods for foreign markets are made to a considerable extent; so are galas, wincies, and hosiery, for home trade. The number of weavers employed by the Perth manufacturers is variously estimated from 1500 and downwards. Linen is made to a small extent by power-looms. A very large traffic, however, is carried on in wood. In this trade, seven saw-mills, driven by steam, of, in the aggregate, seventy-six horse-power, are constantly employed in cutting up the timber for the various purposes for which it is employed. The value of the wood changing hands at Perth is estimated at about L.50,000 per annum; and the larger proportion of it is the produce of the county. The purposes to which it is principally applied, besides house and ship building, are pit-props, barrel-staves, railway-sleepers, and fences. Ship-building is also vigorously prosecuted, giving employment to about 150 to 200 carpenters and others. Agricultural produce, and commodities connected with agriculture, form perhaps the most prominent feature in the commerce of the place. The salmon caught in the river are also an item of some importance in this respect, the great bulk of them being exported from Perth for the London market; the aggregate rent of the salmon-fishings in the Tay being, for the year 1858, L.11,487. The tonnage of vessels visiting the port for the year ending 1st November 1857 was 25,877 tons register; and 57 vessels, measuring 5000 tons, are owned in Perth.

The government of the city is vested in a lord provost, who is also sheriff and coroner; four bailies; a treasurer; the dean of guild, who is *ex officio* a member of the council; and nineteen councillors. There are two city clerks, a procurator-fiscal, and a chamberlain. The city sends a member to Parliament. After Edinburgh was constituted the capital of the kingdom, Perth stood second on the roll of burghs of the Scottish Parliament, and is still entitled to hold that rank. Its chief magistrate has for centuries enjoyed the title of Lord Provost, which was confirmed by a judgment of the Court of Session, 12th March 1836. The Circuit Court of Justiciary is held here twice a year, when the more aggravated criminal offences committed in the counties of Perth, Fife, and Forfar are tried. There are, besides the magistrates and council, two popularly-elected public commissions, the water and police commissions. Under the former, the city is abundantly supplied with water filtered and raised from the Tay, the whole expense of which was defrayed in 1857 by assessments of 2d. and 8d. in the pound upon places of business and dwelling-houses respectively. In police, paving, lighting, and cleansing, the latter commission expended during the year 1856–7, L.4131. The general police assessment was 7d. per pound.

Although divested of much of their ancient political power, and shorn of much of their former state and dignity, the guildry incorporation and the incorporated trades still occupy a prominent and important place in the civic economy of the burgh. The incorporations are the hammermen, bakers, glovers, wrights, tailors, fleshers, shoemakers, and weavers. Several of the incorporations are possessed of considerable property. The dean of guild and the convener of the trades are *ex officiis* members of most of the local boards. Most of the trades possess interesting relics of departed greatness. The principal of these is a very old flag, called "the blue blanket," in the keeping of the convener. This old banner, tradition saith, was borne in the Crusades by a body of burgesses from Perth. The glovers also have preserved in their repositories various interesting mementos; among the rest, a morris-dancer's dress, with

cap and bells, in which some worthy follower of St Bartholomew exhibited for the diversion of Charles I. on the 8th of July 1633. This incorporation also possesses an antique flag, bearing the date 1604. said also to have been borne by some of the craft at the Crusades. The chief memorial preserved by the guildry is the Incorporation Record from 1452 to 1631—a venerable volume in a complete state of preservation, in which are inscribed the autographs of James R., 1601; Charles R., July 24, 1650; Victoria R., 1842; and Albert, 1842.

The burgh has a very large property and revenue, the former derived chiefly from the favour and munificence of several of the Scottish sovereigns. The property of the burgh consists of lands, feus, fishings, mills and waterfalls, dues, seats in the churches, houses, &c.; and its estimated value is L.97,600. The debt of the city, after deducting assets, was, at the 30th September 1857, L.16,518, 2s. 8d. The revenue for the year 1856–7 was L.6052, 13s. 9d., and the expenditure L.3809, 11s. 7d.

In 1856 the navigation and harbour commission was merged in the town council, and the financial affairs of the one conjoined to those of the other (the accounts, however, of the two concerns being kept separate and distinct), by act of Parliament. This, although originally contemplated, was latterly necessitated by the untoward condition of the finances of the commission. In 1854 the obligations of the harbour commission amounted, in round numbers, to L.82,000; while the revenue, in consequence of the successful competition of the railways, had fallen to a trifle over L.1400, being about L.2300 short of its annual liability in the item of interest. The city, being by the Navigation Acts placed in the position of cautionary obligant for the commission, and the surplus revenue of the one not being equal to the deficiency of the other, an act of Parliament was obtained by the town council consolidating the two bodies, with their respective debts and revenues, and converting their conjoined obligations into bonds of annuity bearing a fixed annual interest of 3½ per cent., and also containing power to levy assessments upon the property within the ancient royalty not exceeding 4d. in the pound. The nett obligations on account of the navigation and harbour, at 30th September 1857, was L.85,949, 8s. 2d. But so favourable a turn had the finances of the united bodies taken, that at the same date of the second year of the operation of the act the conjoined surplus revenue over expenditure amounted to L.1022, 9s. 9d.

The large obligations of the navigation and harbour commission were incurred in the construction of new quays, and in the deepening of the river. These works cost together about L.65,000. Besides this, however, the sum of L.31,500 was awarded to the proprietors for injury done by the operations to the salmon-fishings. There is now about 2000 feet of quay berthage at Perth; and ships of 300 tons register can easily ascend the river, the tide rising from 13 to 19 feet at the harbour. For several years the works of the commission fully realized the most sanguine expectations of their promoters; but, as already remarked, the trade of the place has of late been very much diverted from this channel.

The population of Perth, by the last census (1851), is 23,835; inhabited houses, 1991; parliamentary constituency, 933; municipal constituency (1856–7), 636; annual value of real property in 1855–6, L.62,493.

PERTH-SHIRE, one of the most extensive and beautiful counties in Scotland, is almost circular in form, and occupying nearly the centre of the kingdom. Its extreme length from E. to W. is about 70 miles, and its greatest breadth from N. to S. is about 66 miles. Its area is given at 2835 square miles, of which more than 50 are of water. Of the 1,814,063 acres forming its superficial contents, 267,397 were returned in 1857 as under tillage. Many acres are under wood; and a vast extent of highland country affords grazing, pasture, and preserves for game; while only a small proportion of the county can be said to be wholly barren and unproductive. On the E Perthshire is bounded by the counties of Forfar, Fife, and Kinross; on the N. by Inverness and Aberdeen; on the S. by Stirling and Clackmannan; and on the W. by the shires of Argyll and Dumbarton. Its ancient and still popularly-known divisions are,—Monteith, Athole, Strathearn, Breadalbane, Rannoch, Stormont, Perth proper, and Gowrie, to which some add Balquhidder and Glenorchy. It is under the jurisdiction of a sheriff and two substitutes, one of whom resides at Perth, and the other at Dunblane. There are within its boundaries seventy-eight parishes, or portions of parishes, some of them running into other adjacent counties.

Perthshire is distinguished amongst the counties of Scotland for the rich, varied, and picturesque beauty of its surface. From the commanding range of the Grampians, and numerous other secondary elevations, the country slopes gently down into extensive tracts of rich and fertile land, beautifully diversified, and adorned with wood and water, hill and dale, in every possible combination. Where the elevated ranges gradually disappear in the champaign country, nothing can exceed the rich and undulating character of the scenery, broken into noble and irregular valleys, or spreading out into extensive alluvial tracts, watered by streams of almost every size and character. The county of Perth is now generally divided into the Highland and Lowland divisions, the surface of the former being far more extensive than that of the latter. The fertile or Lowland districts lie chiefly, but by no means entirely, towards the eastern and the southern boundaries of the county. The fine valley of Strathearn, having the Grampian range on the N.W., with the Ochils and Sidlaw Hills on the E., traverses it from N.E. to S.W., and, including certain portions of the contiguous valleys of the Tay and the Almond, forms one the richest and most extensive tracts in the kingdom. Besides the extensive valley of Strathearn, there are others of considerable dimensions studded with lakes, and enlivened with streams of every variety of character. Perthshire is likewise distinguished for its noble ranges of mountains, some of which attain a considerable elevation. The highest is Ben Lawers, 3992 feet; Ben More is 3818; Cairn Gower, 3690; and Schehallion, 3613. This last mountain is distinguished by its fine conoidal outline. Benledi rises to the height of 2381 feet; Ben Ardlanach to that of 3500; and Ben Venu to that of 3300; besides many others of considerable though inferior altitude.

The lakes and rivers of this county are numerous. The largest of the lakes are feeders to the Tay, the watershed of the Glen Tilt mountains bounding the county on the N., and that of the Moor of Rannoch on the W. The principal lakes that feed the Tay are lochs Tay, Ericht, Rannoch, Tummel, Lydoch, Garry, Lyon, and Dochart, besides a great number of smaller lakes, the most part of which are situated in the district of Rannoch. The chief streams whose waters find their way into Tay are the Tummel, the Garry, the Lyon, the Lochy, the Dochart, the Braan, the Isla, the Ericht, and the Almond. The highest of these lakes is Loch Ericht, but only about a third of it is in Perthshire. The next highest in point of situation is Loch Lydoch; and the other lakes lying in the Moor of Rannoch. All these lakes and streams abound in fish, some of them containing trout of a very fine quality; and where no natural obstruction exists, salmon ascend almost to their source. The river Tay is the principal river, and is said to discharge more water into the ocean than any river in Britain. Another great drain of the water which falls in this county is the river Earn, which rises in Loch Earn, and falls into the estuary of the Tay a few miles above Newburgh. The streams that fall into this river are numerous, but none of them are of any great size. The river Forth is the boundary of the county on the S., and the lakes and streams that empty themselves into it are numerous and of considerable size; the principal lochs are Voil, Lubnaig, Katrine, Auchray, Vennachir, Ard, and Monteith. Salmon are got in considerable numbers both in the Forth and Earn;

but owing to the want of protection to the spawning fish, and the constant destruction of the young fish in the parr state, they are yearly decreasing, especially in the Forth and its tributaries.

The Tay is a noble river, and the beautiful scenery through which it flows, with its crystal waters running over its gravel bed, and the great volume of water which it is continually carrying to the sea, entitles it to be called the finest river in Scotland. Loch Tay is about 16 miles long, and fully a mile broad, and lies nearly E. and W.; the rivers Lochy and Dochart discharge their waters into it at its head, the village of Killin being between the two streams. The scenery here is of the finest description; and also for 8 miles up Glen Lochy. Salmon ascend the Lochy as far as the falls of Boreland; and for 10 miles farther up the glen the river is well stocked with native trout. The river Dochart is a sluggish stream, but a good angling river. Salmon may be taken in the spring months, and its pearl fishery is well known.

Loch Tay contains salmon, the common trout, and pike. The annual rental of the Marquis of Breadalbane for the salmon-fishery has been, since 1828, L.50. Some very fine fish are taken with the net, during the months of February and March, at Kenmore, where the river Tay issues from the loch. The Lyon river, which joins the Tay a little above Weem, is one of the most inviting streams in the county both for the tourist and angler. It flows out of Loch Lyon, and after running for one-half of its length through a hilly and grazing country, it enters a finely-wooded gorge in the mountains, from which it emerges a little above Fortingal. There are some of the finest beech trees here to be seen in Scotland. This glen is almost unknown to tourists, as, like Glen Lochy, it has no outlet. Loch Lyon is full of very fine trout, and even salmon reach the loch, and have been caught in it. Loch Ericht is the largest lake in the county, and is so deep that the greater part of it never freezes, notwithstanding its high situation; and during the heat of summer its water feels intensely cold, while in winter it is warm. During severe frosts its surface is enveloped in vapour, from the water giving out its caloric. This lake is full of the finest trout, especially at its S.W. end, where it is shallow. The only kinds of fish in its waters are *S. fario* and *S. ferox*; the latter are more abundant than in any other lake in the county. The scenery is of the wildest and grandest description. Ben Alder rises up perpendicular from the lake to the height of nearly 4000 feet; and a cave overhanging the lake is pointed out where "Prince Charlie" hid himself for a season.

Loch Lydoch, in Rannoch Moor, is a beautiful sheet of water about 6 miles long, and has an island covered with trees, upon which the sea eagle builds; in fact the only trees to be found in the moor are around this lake. It abounds with trout; and so does the river Gauir, that flows from it into Loch Rannoch. This lake, which receives also the waters of Loch Ericht, is 11¾ miles long by 1½ broad, and has more the appearance of a Lowland than a Highland lake. On the N. side its shores are clothed with native birch; and on the S. side there are still many miles of the old black wood of Rannoch, which contains some of the finest natural Scotch fir trees in the country. The lake is well stored with an excellent kind of trout, not inferior to Loch Leven, which cut up as red as sea trout; besides *ferox* and *S. salvelinus* or charr. This is a fine lake for the angler, and liberty can easily be obtained to fish it. The river Tummel flows from this lake at Kinloch-Rannoch, and falls into Loch Tummel. Along this part of its course the country around is strewed with rounded boulders to an extent that is hardly conceivable. The scenery around the lake is equal to any in the county; the view from Allean of the lake, the strath, and Rannoch mountains, is very fine. A few miles after leaving the lake the river rushes over the rocky barrier which forms the falls of Tummel. Salmon can ascend no higher than this, and a net is suspended to catch those that make the attempt; which fishing has been regularly let. If a few pounds were spent in blasting the rock, the breeding-ground of the salmon would be greatly enlarged, but this would subject the upper proprietors to close time, which many of them would not like. The Tummel is joined by the Garry near Faskally, at the mouth of the far-famed Pass of Killiekrankie, and after flowing 10 miles, it joins the Tay near Logierait. Loch Tummel contains fine large trout, although they are not numerous, as the lake is also stocked with pike, which have never found their way to any of the lakes farther up. The river Garry flows from the lake of the same name near Dalnaspidal. It is a picturesque, brawling stream, and has some salmon in its pools, but its native trout are small.

The Braan river, which enters the Tay at Inver, near Dunkeld, is for the greater part of its course rapid, and flows from Loch Freuchie, near Amulree. This lake is a favourite resort of the angler, but the trouts are not large. The river Isla empties itself into the Tay at Mickleour. It rises in Glen Isla in Forfarshire, and is a rapid-running stream until it enters Strathmore, when its current for miles is hardly perceptible. Trout are numerous in its waters, and salmon were once so; but pike and eel are very plenty, and the want of sufficient protection to the breeding fish has rendered the salmon-fishing of little value. The Ericht, a picturesque small stream which flows into the Isla a little below Blairgowrie, was not many years ago famous for its salmon; but its waters are so poisoned by public works, and the ascent of the salmon obstructed by dam-dykes, that very few fish are now to be found in it.

The Almond river enters the Tay a little above Perth, but so much of its volume of water is abstracted to supply the neighbouring printfields and mills, that very little of it enters the Tay by its natural channel. Salmon, however, find their way up when the water is in flood; and by the lowering of the fall at Buchanty in Glen Almond, the fish find a great amount of additional spawning-ground in the Sma' Glen.

The river Tay issues from Loch Tay as a large stream, and at once enters and runs through the fine grounds of the Marquis of Breadalbane. Having received the waters of the Lyon a little above Weem, it flows on smoothly until it has to encounter the rocky chasm at Grantully, where there are some fine salmon pools. At Logierait its stream is increased by the junction of the Tummel, which river sends as much water to the ocean as the Tay; still, at the meeting of the waters the Tay appears to be very little increased in volume. A few miles above Dunkeld it enters the grounds of the Duke of Atholl; and no river scenery can be finer than what is met with here. The salmon fishing is very good, but his grace reserves the whole to himself. The view from the bridge of Dunkeld arrests the attention of the tourist; and the scenery on the banks of the river, as it flows through Marthly grounds, is inferior to none in its course. Having reached Mickleour, where it is joined by the Isla, it runs more swiftly, being confined between steep banks, until it rushes over the Linn of Campsie at Stobhall. This fall, when the water is low, may be about 3 feet in height; but when the water is high, no fall is perceptible. The late Professor Anderson of St Andrews stated, in a paper which he read before the Literary and Antiquarian Society of Perth, that after examining the ground with care, it was his opinion that, previous to the river bursting this barrier, its waters followed the course of the Isla through Strathmore, and entered the sea at Montrose or Lunnan Bay. The old bed of the river can yet be distinctly traced in many places; and the numerous lakes still in existence along the old channel bear evidence to the professor's theory. It is a singular fact that a number of Stormontfield-marked *grilse* have been caught in Lunnan Bay. After passing the linn, the river has to pass over the most rugged part of its whole course, the fall being 28 feet in the distance of half a mile. This fall in the river has been taken advantage of for the purpose of driving the machinery of the large cotton-mills at Stanley, which were originally erected by the celebrated Arkwright. Opposite these mills, the *lade* that supplies the Stormontfield bleaching-works is taken off the river; and a little farther down, the *lade* that supplies the Luncarty bleachfield is taken off. A little farther down a remarkable dyke of trap crosses the river, called the Thistle Brig: this trap dyke is very similar to that at the Linn. The whole of the rocks in this gorge, from the junction of the Isla with the Tay to this bridge, are of the old red sandstone formation. About a mile farther down the river are the Stormontfield salmon rearing-ponds, which have thrown so much light on the natural history of the salmon. (See article FISHERIES.) At the junction of the Almond with the Tay, about 2 miles above Perth, the action of the tidal wave ends, rising at spring-tides little more than half an inch. At low-water there is a gentle current from Perth bridge to Newburgh, the fall being about 8 feet. The Tay below Perth is surpassed in beauty by no river in the kingdom. Kinnoull Hill, and the castle and grounds of Kinfauns, are fine features in the landscape on the one side; while on the other are the venerable ruins of Elcho Castle, and Moncrieff Hill. Six miles below Dundee the Tay enters the German Ocean.

Before closing the description of this fine river, a few words will be necessary upon its salmon-fisheries. The net-fishing for salmon and sea-trout on this river is of considerable importance in a national point of view, not only from the quantity, but from the quality of the fish. Until the year 1828, the net-fishing closed on the 26th August; but after that time an act was obtained which altered the time for closing to the 14th of September. The whole assessed annual rental of the Tay in 1828, previous to the alteration, was L.14,574, 10s.; last season (1858) it was L.11,487, 2s. 5d.; although in 1852 it had fallen as low as L.7973, 5s. This state of matters having alarmed the proprietors of the fishing, a new salmon bill was carried through Parliament this last session, making the close time to last from the 26th August until the 1st February for net-fishing, and extending the rod-fishing until the 1st October. This measure has already had the effect of raising the rental nearly up to that of 1828, besides making the rod-fishing very

valuable, which before had fallen so low that very little of the river was let for that purpose. Since the nets were taken off this season, on the 26th of August, the river is swarming with salmon, and anglers have had good sport. Salmon have been caught with the fly on Lord Gray stations, in the tideway, which the oldest fishermen acknowledge they have never heard of before. The protecting force during close time has also been increased; and there is little doubt that in a few years the Tay will become as famous for its salmon-fishing as it once was.

The river Earn, the second largest drain for the waters of the county, rises in Loch Earn, and flows through Strathearn until it reaches the Tay near Abernethy. The upper part of this strath is of considerable elevation, and consequently, until it is joined by the Machany river, a little above Trinity Gask, flows for the most part with a rapid current. Between this part of it and its junction with the Tay it is more like a canal than a river, and when flooded does much damage to the crops in the low grounds. After heavy floods, it generally finds, in various places of its course, a new channel for itself, which is very hurtful to the land upon its banks, although much money has been spent upon embankments. These old courses of the river are full of pike, some of which attain a great size; ducks and water-fowl also abound in them. A considerable quantity of salmon are annually caught in this river. The rental of that part of it near its junction with the Tay, belonging to the Earl of Wemyss, was, for 1858, L.121; for 1829, L.166; the rental of the upper proprietors is not generally known. Salmon ascend as high as Loch Earn, and the best spawning-ground is situated between Crieff and that lake. Besides *Salmo salar*, this river is famous for *S. trutta*, or sea-trout. *S. fario*, or common trout, are abundant; and *Esox lucius*, or common pike, are far too numerous for a large increase of the genus Salmo. The Machany is a beautiful little stream, flowing through the grounds of Lord Strathallan: it is well protected, and abounds in sea and common trout. Strathearn is second to no strath in the county for the beauty of its scenery, and in the lower part of it for the richness of its crops.

The third great drain is the Forth and its tributaries; but as for the greater part of its course it is the boundary of the shire, it will be sufficient to glance at those of its tributaries that are in Perthshire. Loch Katrine, which is about to become the reservoir for supplying the city of Glasgow with water, has been immortalized by Sir Walter Scott. In this lake there is good fishing; it contains *S. ferox*, common trout, and pike. The scenery is so well known that no description is required. Lochs Achray and Vennachir are continuations of Katrine, but, in addition to the fish inhabiting the latter, a few salmon are found in their waters. The stream that flows from these lakes joins the river Teith at Callander. The Teith rises in Loch Lubnaig, a few miles farther up than the last-named village. Loch Lubnaig is a fine sheet of water, and abounds in *S. ferox* and small trout. The Teith contains a few salmon; but the salmon-fishing of the Forth and Teith has fallen off ever since Blair Drummond moss was sent in such quantities into the river; and no increase can ever be looked for until such time as the proprietors see it to be their interest to afford more protection to the spawning fish and the fry. The water of Allan, which enters the Forth at the Bridge of Allan, not many years ago used to be highly esteemed by anglers for the multitude of its sea-trout, but owing to the wholesale destruction of the fry in the parr state that is carried on, it contains now very few. The Forth proper takes its rise from a large spring near the foot of Ben Lomond on the N. side. The spring is so large that from the first it is a considerable stream; but after flowing until it reaches Aberfoyle, it receives the waters that issue from the upper and lower Lochs Ard Lochs Ard are the favourite fishing-ground of the anglers of the west, and contain trout of a very fine quality. The Forth on the whole is a sluggish-running river, and contains salmon, sea-trout, common trout, pike, perch, and eels.

In the more elevated districts of the county, where the mountain ranges slope down into the level country, and amongst the numerous glens which penetrate these in all directions, the climate is charged with moisture in a higher degree, the winters are longer and more severe, the snow frequently lies longer on the ground, and the spring is generally later than in the lower districts of the county. The highest summer temperature rarely exceeds 65°, and the mean temperature, in three different situations in the county (none of them, however, more than 150 feet above the sea), has been found to be 47°. The cloudy character of the atmosphere in the mountainous districts, by intercepting the light of the sun, retards the ripening of the crops, and accumulates moisture, which tends to lower the average temperature. The district of Perth proper is said to be the least humid, the average rain-fall being only 23 inches; but in the Carse of Gowrie, on the shores of the Firth of Tay, the mean quantity of rain for twelve years was 24½ inches; at Perth, for a period of six years, it was 30·30 inches; and at Belmont in Strathmore, for thirty years, it was as high as 30·40 inches. The extensive drainage. executed by various proprietors, has no doubt tended considerably to ameliorate the climate.

As the county may, from its external configuration, so it may also from its geological structure, be divided essentially into Highland and Lowland divisions. The former consists mainly of metamorphic schists, clay, mica, chlorite, and hornblende slates, and gneiss; while the latter is made up of the old red sandstone series The Lowland or southern division of the county is made up of a broad belt of the old red sandstone, which stretches right across Scotland from the Clyde, between Dumbarton and Helensburgh, to the E. coast between Stonehaven and Dundee. Over this belt lie the great valleys or plains of Strathmore, Strathearn, and the Carse of Gowrie. The old red sandstone is bounded on the N. by a very narrow belt, varying from half a mile to 3 miles in breadth, of clay and other slates,—which belt stretches parallel to that last described; also from the Clyde about Helensburgh to the E. coast at Stonehaven. North of this there is a broad band of mica-slate likewise passing across Scotland from the W. to the E. coast. This is succeeded, farther N. still, in the Rannoch district, by quartz rock and gneiss; the latter forming the geological basis of the greater part of the north of Scotland. The sandstone forms level plains; the slates rise into the majestic range of the Grampians. Here and there the strata of sandstone or slate are penetrated by erupted hills of granite or trap,—the former chiefly in the Highland, the latter in Lowland districts.

The northern or Highland part of the county is made up chiefly of the broad range of the Grampians, which at the same time form a natural northern boundary. The slates of which they are chiefly composed, are very variable in structure; passing into each other by insensible gradations. Thus, the clay-slate passes frequently into the graywacke on the one hand, and mica-slate on the other; mica-slate graduates into gneiss, and the latter into quartz rock. One consequence of this is, unequal disintegration by exposure to the weather; and a result of this again is, the peaked or "aiguille-like" form of many of the Perthshire mountains. The clay-slate series may be well studied about Dunkeld. Near Birnam, and on both sides of the river, are extensive quarries of roofing slate of fine quality. The hills on both sides of the river, where the railway from Perth enters the pass or ravine at Birnam, are formed of clay-slate. The clay-slate may here be found passing into graywacke, mica, hornblende, talc, and chlorite slates. Garnets are common in the micaceous slates here; while micaceous iron ore and crystallized chlorite are to be met with at Birnam quarries. The mica-slate about Dunkeld frequently also contains tourmaline, sometimes calc-spar; and on the S. side of Craig-y-Barns there is a vein of copper pyrites. There are abundant evidences about Dunkeld of the depositary action of water in pre-Adamite ages. There are numerous hillocks and mounds of gravel and sand, excellent sections of which, as well as of the clay-slates, may be seen in the railway cuttings. M'Culloch regards the valley above Dunkeld as having once been a lake. The clay and mica slate series may be easily and satisfactorily studied in the classic regions of the Trossachs and Loch Katrine, in the vicinity of Callander, to which there is now ready communication by railway with Edinburgh and Glasgow. The well-known Ben Ledi is formed, on its N.W. side, of mica-slate, and on the S.E. of clay-slate, which, as at Dunkeld and elsewhere, frequently passes into graywacke. Clay-slate is quarried on Ben Voirlich, another hill in the same neighbourhood. Of the Breadalbane hills, Ben Lawers consists chiefly of mica-slate at its base, and skirting Loch Tay this is interstratified with beds of limestone. About Killin the mica-slate passes into chlorite slate, as in Craig Chailliach, which again is frequently penetrated by, or interstratified with, quartz rock. The latter, as well as the chlorite slate, abounds in beautiful needles of the rare mineral *rutile*. A micaceous slate, which occurs along with the chlorite slate on Craig Chailliach, contains hornblende and large cubical pyrites. At Tyndrum the mica-slate joins or passes into quartz rock, and the junction is marked by the occurrence of a rich metalliferous vein, the basis being *galena*, with which, however, are also associated arseniate of cobalt, black cobalt ore, silver, copper pyrites, zinc, blende, sulphate of baryta, and calcareous spar. This vein is traceable for at least 10 miles; it has long been worked for its lead by the Marquis of Breadalbane, to whom it belongs. About Taymouth the slates have the talcose character, and sometimes contain asbestos. Schehallion in Rannoch may be regarded as classic ground, geologically speaking, since this mountain was selected by Drs Maskelyne and Charles Hutton as a site for their experiments on the density of the earth. The upper portion of the hill consists of quartz rock, the lower of mica and hornblende slates. Passing from the Breadalbane to the Atholl mountains and valleys, Glen Tilt at once arrests our attention. It was here that the celebrated Dr James Hutton

Perth-shire.

first obtained physical proof of the correctness of his views on the igneous origin of granite The penetration of quartz rock, gneiss, limestone, and various schists, by granite, may be seen at various points in the glen. This glen is further famed for its marble; the greater part of which is white, and associated with steatite and serpentine; but a portion of which is also of a beautiful flesh colour, with radiating masses of actinolite, asbestos, tremolite, and sahlite, occur in the limestone of this district. Actinolite slate occurs sometimes, interstratified with gneiss, in the valley of the Garry. Kyanite occurs in Cairn Lia; fluor spar, rutile, crystallized mica, and chlorite, in Ben-y-Gloe. This hill, as well as Ben Vrachie and Cairn Gower, consists of quartz rock, with mica-slate and gneiss. Besides Glen Tilt and Loch Tay, limestone also occurs about the Pass of Leny and Aberfoyle, in the western part of the district, and here it is occasionally wrought for agricultural purposes.

We have already mentioned casually, that occasional outbursts, or erupted masses of granite occur throughout the district. At Comrie, in the Lochearn district, granite occurs both in isolated erupted masses, and in the form of a couple of long and large veins or dykes. There is no granitic centre in Perthshire at all. It does not distinctly appear whether there is any connection between this geological phenomenon and the frequent occurrence of earthquakes, for which Comrie is so famous; but the latter would seem traceable to causes acting at no great distance below the surface.

The Lowland or southern division of the district is partly bounded on the S., partly broken up by the ranges of the Ochils and Sidlaws. These may be regarded as branches of the same great trunk. The Ochils are generally regarded as commencing about Stirling, at the Bridge of Allan, and as terminating at Perth. Here they may be considered as dividing into two main branches or continuations, one of which runs down the S. side of the Tay, and terminates at Ferry-Port-on-Craig, constituting Norman Law, Clatchart Craig, and the other hills so prominent about Newburgh. The other stretches along the N. side of the Tay from Perth to Montrose, and divides the great valleys of Strathmore and the Carse of Gowrie; this is generally known by the name of the Sidlaw range. These hills, by whatever name known, are all trappean in their structure, consisting at various points of every gradation and intermixture of basalt, greenstones, amygdaloids, porphyries, compact felspar, tufas, and breccias. The variable structure of some of these hills is very interesting. Moncrieff and Kinnoull Hills, near Perth, are fine mural precipices of trap, rising abruptly from the old red sandstone on the S., and sloping gently towards the N. They run parallel to and closely resemble each other. Moncrieff Hill consists of greenstones, basalt, porphyries, and tufas, passing into each other. Its basalt and greenstones are sometimes obscurely columnar; a phenomenon not unfrequently observed in other hills of this range. Good specimens of the traps of Moncrieff Hill may be procured from the heaps of rubbish thrown up around the ventilating shaft of the tunnel of the Scottish Central Railway, which pierces the hill between the Friartown of Perth and the village of Craigend. These specimens here consist, in great measure, of amygdaloids and tufas, frequently intermixed with much free earth (chlorite). Kinnoull Hill is still more variable in its structure, consisting of basalts, greenstones, porphyries, amygdaloids, tufas, and breccias. Of these, the amygdaloid is perhaps the most interesting, from its abounding in agates and chalcedony calc spar, and drusy cavities lined with amethyst and other forms of quartz. Its basis varies from a basalt to a hardened clay. Kinnoull Hill has long been celebrated for its agates, excellent specimens of which may be seen in the shops of the Perth lapidaries. Specimens are not readily found *in situ*, from the perpendicular and rugged character of the cliffs, but they are frequently to be found on the banks of the Tay between Barnhill and Kinfauns. Chlorite is particularly abundant in all the trap rocks about Perth, frequently in nodules of considerable size; sometimes filling what have been cavities, or diffused through a brecciated amygdaloid. In addition to the Ochils and Sidlaws, which form a sort of backbone of trap to the lowland district of Perthshire, the old red sandstone is pierced by numerous dykes or veins of trap, sometimes of such extent that they can be traced across the whole length or breadth of the district. Hutton speaks of one as running from a little to the S. of Crieff, by Lynedoch and Campsie Linn, in a line N.E. through Strathmore, for about 3 miles. When it comes in contact with limestone the trap sometimes passes into serpentine. Limestone occurs but sparingly in the lowland district. It is, or has been worked, however, at Meigle and Cargill. In connection with some such trap dykes or veins as have been above described, the mineral spring of Pitcaithly is supposed to occur. This, according to the analysis of the late Professor Thomas Thomson of Glasgow, contains chiefly the chlorides of calcium and sodium, and the sulphate of lime. Having probably some similar geological relation or origin is the mineral spring of Crieff, or more properly of Cowgask, near Crieff It was only discovered some eight or ten years ago, and has not yet become so popular or fashionable as it undoubtedly deserves. The water is of the same character as that of Pitcaithly, Airthrey (Bridge of Allan), and Dunblane. According to the analysis of the late Professor Thomas Thomson of Glasgow, the Crieff or Cowgask mineral water contains chiefly the chlorides of calcium, sodium, and magnesium, and the sulphate of lime. According to Professor Christison it contains about 640 grains of saline matter per gallon,—that is, nearly 1 per cent. Great efforts have been made of late years, and are still being made, by the townspeople to render Crieff all that can be desired as a residence for invalids requiring the use of the waters. Before leaving the traps we must not omit to refer to Glen Farg, the amygdaloid of which abounds in zeolites, for which indeed this locality has long been famous. They consist chiefly of analcime, mesotype, stilbite, and prehnite.

The old red sandstone of the Carse of Gowrie and Strathmore consists essentially of the three following beds or divisions:—1. A coarse conglomerate, which may be well seen in some of the river gorges, as at Invermay and Craighall, Blairgowrie, both of which ravines or glens are celebrated for the beauty of their scenery—the former being the subject of Mallet's song of the "Birks of Invermay." At Blairgowrie the imbedded stones are chiefly purple amygdaloids, and other rocks of the trap series. A finer conglomerate may also be seen in the building-stones of Perth bridge. 2. A gray sandstone, which forms the basis of the old red sandstone of the Carse of Gowrie. It may be seen at Dupplin and Dunning in Strathearn. 3. A bright red-spotted sandstone, which lies above the last named, and which is quarried at Inchture, Dunbarnie, Pitfour, and Clashbennie. The two latter quarries are celebrated for their fossil fish, by which this sandstone has been identified, as to its age and position, with the sandstones of the valley of the Eden in Fife. Clashbennie, in particular, is almost classic ground: it was here that the first and finest specimen of the *Holoptychius nobilissimus* was found, which specimen is now deposited in the British Museum. The quarry is about half a mile distant from the Glencarse station of the Perth and Dundee Railway, on the right side of the road between St Madoes and Errol; it is therefore easily accessible. But unfortunately it has not been worked for years, and few of the scales of the *Holoptychius* are now to be had. The beds of dark-red coarse sandstone, containing the scales as originally found, and as they were found by the writer several years ago, cannot now be got at, the section being vertical, or nearly so, with a deep, large pool of water below. Scales may, however, occasionally be picked up among the debris, or purchased from the children of neighbouring cottars for a trifle. On a recent visit, the writer found that a new part of the quarry had just been opened. The stone exposed was much lighter in colour and coarser in texture than that in which the scales were first discovered. It was interlaid with beds of what is locally called "keel,"—a hardened ferruginous clay. Some layers also had a conglomerate character, the imbedded nodules consisting chiefly of the ferruginous slate-clay just mentioned. Among the conglomerate chiefly, scales and ichthyodorulites of the *Holoptychius* were not uncommon; but they were generally smaller, and with the groovings or sulci less distinctly marked than in those formerly found. The texture of the scales was generally replaced by carbonate of lime (calc spar). Carbonaceous impressions are comparatively common in some beds of the old red sandstone: they are supposed by some authorities to be of vegetable origin, but their nature has not been satisfactorily determined. Another source of considerable doubt and discussion has been the yellowish or pale circular spots on the bright-red sandstone, as it occurs at Inchture and other quarries of the Carse of Gowrie. It is generally supposed that the presence of minute organisms of some kind, for they are not now visible, may have been the means of discharging the colour over limited spots or localities. The old red sandstone is sometimes of the character of marl, containing a considerable proportion of carbonate of lime. This renders it very serviceable to the farmer. Sandstone-marl occurs at or near Stanley, on the Tay; near Perth; Lynedoch, on the Almond, also near Perth; and at Abercairney, near Crieff.

Superimposed upon the old red sandstone in the Carse of Gowrie is the great alluvial deposit of the "Carse clay." This may be divided into the following beds or strata:—1. A boulder clay, which forms the basis of the rest; 2. A blue clay proper; 3. A peat, containing roots, branches, leaves, and fruits of trees; and, 4. The Carse clay proper—a mixture of sand and clay, the latter predominating. In the latter, about five feet above the peat, and considerably above the present high-water mark, is a bed of marine shells. These consist entirely of existing littoral species, being mostly made up, in specimens which we have examined, of the *Cardium edule*. The peat would appear to have given rise to some discussion among geologists as to its nature and origin. The late

Professor Fleming of Edinburgh has described it as a submerged forest, due to subsidence of the banks of the Tay; but Dr Buist of Bombay controverts this idea. It may be examined about Errol and Pitfour; and throughout the Carse it will be found to be of pretty uniform dimensions and contents.

On the lessons taught by the structure of the Carse clay we cannot here enter. It is supposed by some local geologists, who have bestowed much attention on the subject, that at one time a depression of the land below sea or estuary water occurred, and that this was followed, at some considerable lapse of time, by an elevatory action. The existence of the peat—its present situation, and the presence in it of roots apparently *in situ*, and of the leaves and fruit of forest trees, are explained on this hypothesis. Evidence is very contradictory. Remains of boat-rings and staples have been found considerably below, as well as considerably above, the present river or sea level, apparently coeval in date, and of course belonging to the human epoch. It is impossible to admit, as some would have us to do, these as proofs of movements of elevation and depression, occurring at the same time and in the same place. Doubtless much error has been introduced by traditions which have not been founded on facts.

There are few counties in Scotland which can boast of the same variety and richness of their flora as Perthshire. In the northern and southern divisions of the county are to be met with some of the rarest plants in Scotland. Ben Lawers, for instance, is, botanically speaking, classic ground; and its alpine flora is perhaps as rich and rare as that of the more famed Clova. We cannot pretend to give anything like a vidimus of the flora of Perthshire. All that we can here attempt is to give a brief enumeration of the rarer plants only of the district, leaving the reader to infer therefrom the character of the more ordinary vegetation.

Referring first to the northern or Highland section of the county, Ben Lawers alone is the habitat of the following rare alpines:—*Saxifraga cernua*, *S. rivularis*, *Erigeron uniflorus* (which is probably a mere form of *E. alpinus*), *Veronica fruticulosa*, *Eriophorum capitatum* (according to Don, who, however, has probably confounded it with *E. vaginatum*), *Carex rupestris*, *C. curta*, *C. ustulata*, *Woodsia hyperborea*, *Poa nemoralis*, var. γ (of Hooker and Arnott's *Flora*), *Triticum caninum*, var. β, *Cystopteris montana*, *Salix arbuscula*, var. β, *Bartsia alpina*, *Draba verna*, var. β, *D. rupestris*, *Sagina saxatilis*. On other members of the Breadalbane range of mountains occur the following:—*Cherleria sedoides*, *Arenaria verna* (Mael Duncrosig), *A. rubella*, *Cerastium alpinum*, *Potentilla alpestris*, *Sibbaldia procumbens*, *Rosa involuta* (near Meggarnie in Glen Lyon), *R. cæsia* (valleys), *Epilobium alsinifolium*, *E alpinum*, *Saxifraga stellaris*, *S. nivalis*, *S. oppositifolia*, *Hieracium pallidum*, *H. strictum*, *Erigeron alpinus*, *Azalea procumbens*, *Arctostaphylos alpina*, *Myosotis alpestris*, *Veronica saxatilis*, *Bartsia alpina* (Maelgrædha, Corrach-Uachdar, &c), *Melampyrum sylvaticum*, *Plantago maritima* (Glen Dochart, and also on summits of highest mountains), *Salix arenaria*, var. α, *S. Myrsinites*, var. ..(Craig Chailliach), *S. procumbens*, *S herbacea*, *S. lanata* (Mael-Uachdar, near Killin), *Juncus castaneus*, *J trifidus*, *J. biglumis*, *J. triglumis*, *Scirpus sylvaticus* (about Killin), *Kobresia caricina* (Shroine-ach-Lochan), *Carex Bœnninghausiana* (Killin), *C atrata*, *C. rigida*, *C. saxatilis*, *C. vaginata* (Craig Chailliach and Corrach-Uachdar near Killin), *C. capillaris*, *Phleum alpinum*, *Cystopteris montana* (Corrach-Uachdar, &c.), *Equisetum palustre*, var. β. The following grow on the Atholl mountains:—*Carex capillaris* (Ben-y-Gloe), *Crepis succisæfolia* (Falls of Tummel), *Gnaphalium sylvaticum*, var. β (Ben Chat near Blair Atholl), *Campanula rapunculoides* (Blair Atholl), *Menziesia cœrulea* (on the "Sow of Atholl," Dalnaspidal), *Polygonum verticillatum* (Blair Atholl), *Tilia grandifolia* (Blair Atholl), *Rubus arcticus* (Ben-y-Gloe), *Cryptogramma crispa* (on Birnam Hill), *Genista anglica*, *Trientalis europœa*, *Listera cordata*, *Callitriche autumnalis* (Loch of Cluny), *Lactuca virosa* (Dunkeld), *Stratiotes aloides* (Loch of Cluny), *Gymnadenia conopsea*, *Habenaria albida*, *Butomus umbellatus* (Loch of Cluny, introduced), *Asplenium alternifolium* and *A. septentrionale* (Stenton Crag, Dunkeld). To these may be added as growing in the Highland division of Perthshire—*Pimpinella magna* (banks of the Teith), *Linnœa borealis* (in fir woods in different parts of the county), *Salix ambigua*, var. α, *Elatine hexandra* (Loch Ruisky near Callander), *Silene acaulis*, *Ulex nanus* (Dalguise), *Potentilla opaca* (Braes of Balquhidder). In the lowland division of Perthshire we find its flora equally rich and varied. The most interesting plants of this section are probably *Scheuchzeria palustris* (abundant in a marsh on the side of the Methven road, 4 miles from Perth), *Monesis grandiflora* (abundant in a fir wood about 1½ to 2 miles beyond the village of New Scone), *Teucrium chamædrys* (Methven Wood), and *Turritis glabra* (Redgorton). But the following plants, also, are of great interest. In the Methven district, including the woods and grounds of Methven and Lynedoch and the valley of the Almond, occur *Corallorrhiza innata*, *Epipactis grandiflora*, *E. ensifolia*, and *E. latifolia*, *Listera nidus-avis*, *Paris quadrifolia*, and *Erigeron alpinus*, the seeds of which would appear to have been carried by the Almond from the Breadalbane mountains. The Redgorton district, which includes a portion of the banks of the Tay, possesses *Peplis Portula*, *Nuphar lutea*, *Nymphœa alba*, *Thalictrum minus*, *Hypericum humifusum*, *H. hirsutum*, *H. pulchrum*, *H. quadrangulum*, *H dubium*, *Cichorium Intybus*, *Bidens tripartita*, *Cnicus eriophorus*, *C. heterophyllus*, *Trientalis europœa*, *Adoxa moschatellina*, *Chelidonium majus*, *Habenaria viridis*, *H. bifolia*, and *Listera ovata*. In the Carse of Gowrie district, which includes the salt marshes on the banks of the Tay, between Perth and Dundee, the alluvial plain of the carse proper, and the "Braes of the Carse," or the southern declivities of the Sidlaw range of hills, are to be found *Galium saccharatum*, *Cynoglossum sylvaticum*, *Calamintha Acinos*, *Poterium Sanguisorba*, *Pyrola rotundifolia* and *P. media*, *Lotus corniculatus* var. *tenuifolia*, *Centaurea scabiosa*, *Stachys arvensis*, *S palustris*, *Galeopsis Ladanum*, *Ranunculus hirsutus*, *Chrysosplenium alternifolium*, *Leonurus Cardiaca*, *Scrophularia vernalis*, *Typha angustifolia*, and *Dianthus Armeria*. In the Kinnoull and Perth district, which includes the hills of Kinnoull, Moncrieff, and Craigie, and the Glen of Balthayock, occur *Ceterach officinarum*, *Sagina ciliata*, *Lychnis Viscaria*, *Geranium columbinum*, *Sedum anglicum*, *S. album*, *Potentilla argentea*, *P. reptans*. In the Strathearn district, including Invermay, Dupplin, and Glen Farg, occur *Dentaria bulbifera*, *Doronicum Pardalianches* and *plantagineum*, *Listera nidus-avis*, *Rumex alpinus*, *Mentha viridis*, *M. piperita*, *Lychnis Viscaria*, *Betonica officinalis*. To the foregoing we may add *Nepeta Cataria*, between Culross and Kincardine, on the Forth; *Viscum album*, Mickleour Woods, introduced; *Galium pusillum*, Ochil and Strathblane Hills; *Dipsacus sylvestris*, abundant on Kinnoull Hill; *Lactuca virosa*, of great size, on the talus at the foot of Kinnoull Hill; *Hieracium strictum*, Ochils; *Cnicus arvensis*, Culross, on the Forth; *Doronicum Pardalianches*, island at the junction of Almond and Tay; *Campanula latifolia*, Invermay Woods; *C. glomerata*, banks of Tay, near confluence of Almond; *Thalictrum minus* β *majus*, island at junction of Almond and Tay; *Helleborus fœtidus*, Scone Woods; *Hypericum barbatum*, according to Don, at side of a hedge near Aberdalgie, Strathearn; *Ornithopus perpusillus*, near Perth; *Agrimonia agrimonioides*, Dundee road, near Perth; *Vicia tetrasperma*, Ruthven, near Perth; *Senecio aquaticus*, *Scirpus triqueter*, and *S. lacustris*, marshes on the Tay, immediately below Barnhill Toll; *Astragalus glycyphyllus* and *Vicia sylvatica*, banks of Almond, a short way above its junction with the Tay.

Equally interesting with the Phanerogamic is the Cryptogamic vegetation of the district; but more than a mere passing allusion, want of space compels us to omit.

In a county of so great extent, and possessing such a variety of surface, considerable diversity must exist in the character of the soil. The carse or alluvial lands on the shores of the Frith of Tay have long been celebrated for their fertility. They are considered as the joint produce of river and sea deposition for a series of ages. The general character of the soil is that of a rich clay, very deep, in some places alternating with layers of peat, and having sand and marine deposits at the bottom. This soil is not wholly alluvial, being sometimes mixed with the debris of trap-rocks, and also of the sandstone, which, as already mentioned, forms a geological characteristic of the lowland districts of Perthshire. Considerable tracts of this inferior description of alluvial soil are found accompanying the courses of the principal rivers, and extend into the upper portions of Strath Tay, Strath Airdle, and Strath Tummel. A soil composed of clay and sand, and called by agriculturists a *till*, extends along a vast tract of this county from E. to W., and is supposed to be formed from the red sandstone prevalent in that district. Peat is to be met with almost everywhere in Perthshire; that known by the name of *Flanders Moss* is said to extend over 10,000 acres, and is amongst the largest continuous tracts of this description in the United Kingdom.

In the arable districts of this county, such as the Carse of Gowrie, and the fertile lands skirting part of the course of its principal rivers, the modes of agriculture and management of farms are much the same as in the other agricultural counties of Scotland. Drainage has been effected to a very large extent; new discoveries and inventions in the theory and practice of tillage are freely adopted, and the spirit of improvement and enterprise very fully pervades the agricultural population. The arable farms vary in extent from 50 to 500 acres and upwards: and in the Carse of Gowrie the rents are as high as in any part of the kingdom. Wheat is largely raised on the best soils, and not unsuccessfully even in several of the Highland districts. In the wheat-growing soils this crop usually alternates with beans and peas, barley, hay, and oats. The agricultural statistics of Scotland give the number of acres in this county under the different kinds of crop in 1857 as follows:—Wheat, 25,638; barley, 18,802; oats, 64,084; rye, 77; bere, 655; beans, 3949; peas, 301; vetches or tares, 1241; turnips, 33,313; potatoes, 17,482; mangold, 33; carrots, 32; cabbage,

Perthshire.

42; rape, 8, flax, 15; turnip-seed, 205; other grain or root crops, 17; bare or summer fallow, 1840; grass and hay under rotation, 99,656. The pasture-farms in the higher parts of the county are large, and raise great numbers of sheep. Other descriptions of live stock are also largely cultivated. Dairy farming does not form a prominent feature in the rural economy of this county. In some favoured spots orchards succeed well, many of them are very large, and their produce is highly celebrated. Perthshire is remarkable for the great extent and beauty of its woods. Of these, many are of natural wood, chiefly oak. But extensive plantations of various kinds of trees have been made during the last 50 or 60 years by several proprietors, especially by the late Duke of Atholl, whose planting operations were carried on upon the most extensive scale, at once beautifying and enriching one of the finest parts of the county. To him Perthshire is indebted for the introduction of the larch, which has been found singularly adapted to the climate and soil. The plantations of this tree have thriven amazingly, and are of great extent and value. In 1674 the valued rental of Perthshire was L.28,324 sterling; in 1815 the annual value of assessed property amounted to L.555,552 sterling; and in 1858 the valuation made up in terms of the recent Valuation Act amounted to L.677,114, 9s 9d.

This county is particularly rich in splendid seats and mansions belonging to the great proprietors. Of these, the most remarkable are Taymouth Castle, the palace of Scone, Kinfauns Castle, Murthly House, Dupplin Castle, Rossie Priory, and Blair Castle. Castle Huntly and Blair Castle are fine specimens of the old baronial and castellated habitations of the ancient lords of the soil; and Doune Castle is considered as one of the finest ruins of its kind in Scotland. Perthshire is not remarkable for antiquities, secular or ecclesiastical. Druidical circles and Roman remains are found in various places. Of the former, one circle almost entire, called by the country people "Standing Stanes," formerly existed at Craigmakerran, the property of the guildry of Perth; but about 40 years ago it was barbarously destroyed, and the stones blasted for the purpose of being employed in the erection of a farm-steading. Before this act of vandalism was committed, the circle in question, which stood on a projecting crag about 6 miles from Perth, on the Isla road, was perhaps one of the most perfect of the kind in the kingdom. Of the latter, the camp or station at Ardoch and that at Comrie are well known, as well as the Roman road which seems to have connected them. There is another at Delvin, which is scarcely less remarkable. The ruins of the cathedrals of Dunblane and Dunkeld are also in excellent preservation, though the architecture is by no means of the highest order. The tower of Abernethy, which has long puzzled the heads of antiquaries, is unfortunately decaying rapidly, as is also the fine old abbey of Culross.

In the animal kingdom there is little peculiar to the county. Game beasts and birds of every description abound in their respective districts. These are everywhere strictly preserved, and the sport furnished in the county forms a very considerable item of its wealth.

The principal towns are,—Perth and Culross, which are royal burghs; Crieff, Callander, Kincardine, Doune, Comrie, Dunblane, Auchterarder, Dunkeld, and Blairgowrie. The villages are numerous, and many of them populous and thriving. The greater part of Coupar-Angus is included in the county of Perth.

Mills for spinning flax, bleachfields, and calico-printfields, are numerous; and there are some large establishments for spinning cotton-yarn at Stanley, near Perth, and at Deanston. Oil-mills are also to be found in various places. The tanning of leather is carried on to a considerable extent at Crieff and at Thornhill. Wool is likewise an article of considerable sale. From the more fertile districts large quantities of grain are annually brought to market. Bark and timber, principally larch and oak, also form commercial articles of no small importance. The produce of its fisheries has already been noticed as being among the list of exports.

The population of the county of Perth amounted in 1831 to 142,166, being an increase since 1821 of 3919. In 1841 it was 137,457; and in 1851, 138,660. In the last-mentioned year Perthshire contained in all 196 places of worship, with 84,583 sittings. Of the former, 59 belonged to the Established Church, 60 to the Free Church, 35 to the United Presbyterians, 10 to the Episcopalians, 8 to the Baptists, 7 to the Independents, 5 to the Roman Catholics, 3 to the Original Secession, 2 each to the Relief Church and Wesleyans, and 1 each to several smaller sects. The number of day schools was 307 (221 public and 86 private), with 21,143 scholars. There were also 230 Sabbath schools, with 16,294 scholars; 19 evening schools, with 464 scholars; and 10 literary and scientific institutions, with 693 members. The county sends a member to Parliament, as does also Perth, the principal city. Culross, Queensferry, Dunfermline, Inverkeithing, and Stirling, unite in returning a third.

Perthes.

PERTHES, Christoph Friedrich, an eminent German bookseller, was born at Rudolstadt on the 21st of April 1772, known in Germany as "the great hunger year." His father, who was secretary of the exchequer to the house of Rudolf Schwartzburg, died in 1777, and left his widow and child almost entirely unprovided for. The fatherless boy had the good fortune, some years afterwards, to be taken in charge by his maternal uncle, a state official, and a man of great uprightness and kindliness of disposition. After spending in a somewhat unsatisfactory manner some years at the gymnasium of his native town, he was apprenticed to one Böhme, a bookseller in Leipzig, on the 11th September 1787. Perthes was passionately fond of reading; and if he no longer found leisure to indulge his propensity for perusing books, he at least got plenty of them to carry through the streets of Leipzig. After six "happy years of earnest striving," as he calls it, in the strict service of this rough, honest old bookseller, relieved not a little at times by the smiles of his fair daughter Frederika, Perthes, no longer in abject poverty, and full of enthusiasm, set out for Hamburg in 1793, to assist one Hoffman, an extensive publisher in that city. After a three years' residence there, during which he laboured hard to improve his education, both by careful study and by cultivating the friendship of men of intelligence and worth, he entered into partnership with an old fellow-apprentice named Nessig. This copartnery soon broke up, however, and Perthes continued on his own account. Bookselling with Perthes was, even at this time, something more than a mere commercial employment. The moral influence of the trade he considered to be very great, if only the booksellers could be brought "to care more for honour than gold." He accordingly resolved to aim at a thorough reform of his profession in Germany. His acquaintance with literary men was already extensive, and the ready intelligence, thorough business habits, and honest, genial temper of the young publisher, gradually drew around him the most eminent literary men of his time in Germany. He was already held in esteem by the Stolbergs, by Voss, and by Count Reventlow; and he regarded Jacobi, "the German Plato," with the love and reverence of a father. On the 2d of August 1797 Perthes married Caroline, daughter of Claudius, editor of the *Wandsbecker Bote*, and one of the noblest women Germany has yet known. In the following year he entered into partnership with Besser, who was his superior both in education and in his knowledge of books, and set steadily to work to make their firm the medium of the literary intercourse of the nations of Europe. The blockade of Hamburg by the French in 1803 brought trying times to these enterprising men, which a long series of years of trouble and anxiety hardly brought to a close. The French having regained possession of Hamburg, after their expulsion by the Russians in 1813, devastated the town, plundered Perthes' shop, and closed it up as sequestrated. As one of the ten who were refused pardon for their staunch resistance of foreign oppression, Perthes was forced to fly. His wife, who, with her children, had found a refuge at Wandsbeck, was, despite extreme privation, devoutly thankful "that your [Perthes'] name stands among the ten enemies of the tyrant." By the exertions of Besser, business was again resumed in 1814. Having lost his wife in 1821, Perthes removed from Hamburg, and, settling at Gotha, commenced an extensive business as a publisher, chiefly of works in theology and in history. He brought out the works of Neander, Ullman, Tholuck, and Bunsen in theology, and of Niebuhr and other eminent writers in history. Niebuhr had the greatest regard for Perthes, always spoke admiringly of his "glorious power," and esteemed his judgment of books as superior to that of most men in Germany. Perthes married a second time in 1825; ultimately resigned his business

to his son Justus, who continues to carry it on; and having retired to the neighbourhood of Gotha, this good man died on the 18th of May 1843.

A highly instructive and entertaining Life of Perthes was published by his son Clemens Theodor, professor of law in the university of Bonn, in 3 vols. 8vo, 1848-55. This work has been translated into English, with some condensation, and published under the title of *Memoirs of Frederick Perthes; or, Literary, Religious, and Political Life in Germany from* 1789 *to* 1843, 2 vols. 8vo, Edinburgh, 1856. There is also an abridgment of this work, entitled *Life and Times of Frederick Perthes*, 1 vol. 8vo, Edinburgh, 1858. In addition to these memoirs of his father, C. T. Perthes has written *Der Deutsche Staatsleben vor der Revolution*, 1845; and *Einverleibung Krakaus, und die Schlussacte des Wiener Congresses*, 1846.

PERTINAX, Helvius, a Roman emperor, was the son of an humble wood-merchant and charcoal-burner, and was born in 126 A.D., according to some in Liguria, but according to others at Villa Martis, among the Apennines. The prudence and integrity of his character raised him rapidly from his native obscurity. From being a teacher of grammar, he passed gradually through many important offices, both civil and military, twice holding the consulship, and governing in succession most of the provinces in the empire. At length, on the last day of the year 192, he was chosen to succeed the murdered Commodus. His death took place by assassination eighty-six days afterwards, in the sixty-seventh year of his age, after a reign of two months and twenty-seven days. (See Roman History.

PERTUIS, a town of France, in the department of Vaucluse, on the Lese, not far from its confluence with the Durance, 18 miles S.S.E. of Apt, and 41 E.S.E. of Avignon. It is surrounded with ramparts; and contains a fine church and a college. Woollen yarn, earthenware, and brandy are made here; and there are also dye-works, brick and tile kilns, &c. Some trade is carried on in grain, wine, brandy, and oil. Pop. 4776.

PERU.

Peru, a republic of South America, lies between 3. 35. and 21. 48. S. Lat., and 68. 10. and 81. 30. W. Long. It is bounded on the N. by the republic of Ecuador, W. by the Pacific Ocean, and E. and S. by the territories of Brazil and Bolivia. Its extreme length from N. to S. is about 1250 miles, and its breadth varies from 60 to about 750 miles, the width increasing gradually from S. to N. The coast-line stretches along the Pacific from the mouth of the Rio Tumbez on the N. to that of the Rio Loa on the S. The area may be roughly estimated at about 500,000 square miles.

The present state comprehends only a small portion of that vast empire over which the Incas exercised their sway at the time of the Spanish invasion. The ancient empire of Peru extended over nearly forty degrees of latitude, from the second degree of north to about the thirty-seventh of south latitude. Its breadth, however, must have been altogether disproportioned to its length; but the exact limits cannot now be determined. It extended eastward from the shores of the Pacific, in many parts considerably beyond the mountains, to the confines of barbarous states whose position cannot now be ascertained.

Early inhabitants.

Of the various traditions respecting the early inhabitants of Peru, the one best known is that which ascribes the introduction of civilization to Manco Capac, the first of the Incas, who is said to have flourished in the early part of the twelfth century. At the time of his advent the people were among the most barbarous of the American savages, roaming over the country without any fixed place of abode, at constant war with each other, and feasting on the flesh of their slaughtered captives. The sun, however, the great luminary and parent of mankind, taking compassion on their degraded condition, sent his son Manco Capac with Mama Oello Huaco, at once his sister and his spouse, to reclaim and civilize them. He taught them to till and irrigate the soil, to construct residences, and to worship the sun; and farther, instructed them in the moralities of life, and framed wise and benevolent laws for their guidance. The empire, which at first comprised only a small territory around the city of Cuzco, gradually extended its authority over the surrounding tribes, until it became the first in size and importance of the South American States, occupying here a position equally prominent with that of Mexico in North America. Another legend, probably not less generally received among the Peruvians, but one which is less known among other nations, speaks of certain white and bearded men who, advancing from the shores of Lake Titicaca, established an ascendancy over the natives, and imparted to them the blessings of civilization. None of these legends, however, throw any light upon the early history of the people. The date usually assigned to these events, 400 years before the conquest, is manifestly too early, as none of the accounts assign to the Inca dynasty more than thirteen princes, a number much too small to extend over such a period. There is also reason to believe that there existed in the country a race advanced in civilization before the time of the Incas, and the extensive architectural remains still existing on the shores of Lake Titicaca, evidently of a date anterior to the pretended advent of the Incas, would indicate that as their original seat. Who this race were, and whence they came, is a tempting theme for speculation, but lies far beyond the domain of history. It is only as we approach the time of the Spanish conquest that we begin to emerge from the impenetrable mists that overhang the early annals of the country. In the middle of the fifteenth century the famous Topa Inca Yupanqui, grandfather of the monarch who occupied the throne at the coming of the Spaniards, led his armies across the terrible desert of Atacama, and penetrating to the southern region of Chile, fixed the permanent boundary of his dominions at the River Maule. His son Huayna Capac, possessed of ambition and military talent fully equal to his father's, marched along the Cordillera towards the north, and pushing his conquests across the equator, added the powerful kingdom of Quito to his possessions.

Ancient Peru.

Were the accounts given by the earlier writers of the state of the country and of its inhabitants at the period of the conquest not borne out by existing remains, and corroborated by what we know of such nations as the Chinese and Japanese of the present day, they would be quite incredible. The surface of the country was naturally very unfavourable for the purposes of agriculture. A sandy tract, seldom or never refreshed by rain, and watered only by a few scanty streams, extended along the coast, beyond which was the steep and rocky range of the Cordillera. But notwithstanding this unpropitious nature of the country, by means of a judicious system of artificial irrigation, an abundant supply of provisions was raised for a numerous population. Canals and subterraneous aqueducts were constructed in all directions, and terraces were raised upon the steep side of the Cordillera, where the productions of temperate and northern, as well as of tropical countries, were reared. Traces of these water-conduits are still to be seen in all parts of Peru. They were formed of large slabs of freestone nicely fitted together, and were sometimes several hundred miles in length, carried through rivers and marshes, and not unfrequently tunnelled through the solid rock. The earth to the terraces had frequently to be brought from a considerable distance; and not uncommonly was the arid soil of the valleys and plains

removed in order to reach a lower stratum more suitable for cultivation. They further made large use of the different kinds of manures, with the properties of which they were well acquainted. Guano especially, that valuable manure which has attracted so much notice of late years, was largely employed by them. Still more remarkable as monuments of labour and ingenuity were the great roads which traversed the kingdom in various directions, the remains of which are still in sufficient preservation to attest their former magnificence. The most remarkable of these were the two which extended from Quito to Cuzco, and again diverging from the capital, were continued in a southern direction towards Chile. "One of these roads passed over the grand plateau, and the other along the lowlands on the borders of the ocean. The former was much the more difficult achievement, from the character of the country. It was conducted over pathless sierras covered with snow; galleries were cut for leagues through the living rock; rivers were crossed by means of bridges that swung suspended in the air; precipices were scaled by stairways hewn out of the native bed; ravines of hideous depth were filled up with solid masonry; in short, all the difficulties that beset a wild and mountainous region, and which might appal the most courageous engineer of modern times, were encountered and successfully overcome. The length of the road, of which scattered fragments only remain, is variously estimated from 1500 to 2000 miles; and stone pillars, in the manner of European mile-stones, were erected at stated intervals of somewhat more than a league all along the route. Its breadth scarcely exceeded 20 feet. It was built of heavy flags of freestone, and, in some parts at least, covered with a bituminous cement, which time has made harder than the stone itself. In some places where the ravines had been filled up with masonry, the mountain torrents, wearing on it for ages, have gradually eaten away through the base, and left the superincumbent mass—such is the cohesion of materials—still spanning the valley like an arch." (Prescott.) "The great road of the Incas," says Humboldt, a man not given to exaggeration, "was one of the greatest and most useful works ever executed by man." Their bridges were constructed of the tough fibres of the *maguey*, or of the osier of the country, woven into cables of the thickness of a man's body. Several of these enormous cables, bound together, and attached at each end, formed the bridge, which was covered with wood, and well secured by a railing on each side. As the length of this bridge sometimes exceeded 200 feet, and as it was supported only at the extremities, it presented an alarming inclination towards the centre; while the motion given to it by the traveller caused an oscillation still more frightful, as his eye wandered over the dark abyss of waters that foamed and tumbled many a fathom beneath. Yet these light and fragile fabrics were crossed without fear by the Peruvians. In the level country the broad and tranquil rivers were passed in *balzas* or floats, to which sails were attached,—the only instance of their use among American Indians. All along these highways caravanserais, or *tambos* as they were called, were erected at the distance of 10 or 12 miles from each other, for the accommodation more particularly of the Inca and his suite. Some of these were very extensive, consisting of a fortress, barracks, and other military works, and were evidently destined for the accommodation of the imperial armies when marching across the country. Posts were also established along all the great routes, and stations were erected within short distances of each other, where runners were stationed to carry forward dispatches. Messages were thus carried through the country at the rate of 150 miles a day. At the time of the conquest of Peru no nation in Europe could boast of any work of public utility that could be compared with the great roads of the Incas.

The industry and ingenuity of the Peruvians was also shown in the construction and ornamenting of their temples and palaces. The ruins of these magnificent edifices, which are to be found in many parts of the country, attest at once the great power of the Incas, and the high degree of knowledge in the arts to which the people had attained; whilst they also show that, during two centuries at least, the nation must have subsisted in a state of considerable advancement. They were usually low, but covered a vast extent of ground, and were constructed of blocks of stone, some of them of great size, but of no regular form; and though no cement was used, they were adjusted to each other with such exactness that it was impossible to introduce even the blade of a knife between them. Some of these stones were full 38 feet long, by 18 broad, and 6 thick. They were hewn from their native bed and fashioned into shape by a people ignorant of the use of iron; they were frequently brought from great distances, across rivers and ravines, up to a great elevation on the sierra, and finally adjusted with the nicest accuracy, without the aid of beasts of burden or machinery of any kind. The interior of the palaces was adorned with the finest and most costly materials. "The sides of the apartments were thickly studded with gold and silver ornaments. Niches prepared in the walls were filled with images of animals and plants, curiously wrought, of the same costly materials; and even much of the domestic furniture, including the utensils devoted to the most ordinary menial services, displayed the like wanton magnificence!" (Prescott.) The magnificent Temple of the Sun at Cuzco covered a great extent of ground in the centre of the city, and was surrounded by a wall. Such was its splendour, that a Spaniard who saw it in its glory asserts that there were only two edifices in his own country that could, in point of workmanship, be compared with it. Every part of the interior was richly ornamented with gold. On the western wall, and so situated that the rays of the sun struck directly upon it at his rising, was a figure of their god, engraved on a massive plate of gold of enormous dimensions, thickly studded with emeralds and precious stones. All the ornaments of the temple, and every kind of utensil appropriated to the uses of religion, were of gold or silver. Adjoining the principal structure were several chapels of smaller dimensions, one of which was consecrated to the moon,—the deity held next in reverence to the sun, as the mother of the Incas. Besides the Temple of the Sun, there are said to have been no fewer than four hundred inferior temples and religious houses in the Holy City. Other temples and religious houses were scattered over the provinces, some of them constructed on a scale of magnificence that almost rivalled that of the metropolis.

The Peruvians manifested great skill and ingenuity in the manufacture of ornaments of various kinds. Here, however, like the Chinese and some other eastern nations of the present day, their works are characterized more by minuteness in imitation or delicacy of finish than invention or beauty of design. Many specimens of elaborate workmanship have been dug out of the *huacas*, or sepulchral mounds. They comprise vases of gold and silver; bracelets, collars, and other ornaments for the person; utensils of every description; and mirrors of hard, shining stones, highly polished. Though iron exists in the country, they were unacquainted with its use. Their tools were of stone, or more frequently of copper; but they had also a composition of copper and a small quantity of tin, which had almost the hardness of steel. In their textile manufactures they likewise manifested considerable skill. Their vast flocks of sheep, and the cotton which grew luxuriantly on the coast, supplied them with abundant materials for clothing; and they also manufactured a species of cloth from the tough thread of the maguey tree. Some of their woollen manufactures were of such delicacy and beauty, that the Spanish sovereigns, with all the luxuries of Europe and Asia at their command, did not disdain to use them.

The government of Peru was a despotism, mild in its character, but pure and unmitigated in its form. The sovereign was the source of all power and all authority, and stood at an immeasurable distance from even the highest of his subjects, none of whom could venture into his presence unless barefoot, and bearing a light burden upon his shoulders in token of homage. As descended from, and as representative on earth of the sun, his person and acts were endowed with a sacredness that no merely secular position could confer upon them; and hence any disobedience of his law was looked upon as sacrilege. But, while vested with all this power, the sway of the Incas was not a tyrannical one. They sought rather to imitate their supposed progenitor the sun, and to promote the welfare and happiness of all their subjects. Though so immeasurably above his subjects, there were occasions when he condescended to mingle with them. He presided at some of the religious festivals; and at intervals of several years he travelled in great pomp and magnificence through the empire, inspecting and inquiring into the condition of the various classes of his subjects. Once a year, too, he repaired to a field in the vicinity of the capital, and there, in presence of his court, and a vast assemblage of the people, turned up the earth with a golden plough. The nobility of Peru were of two orders,—the *Incas*, or descendants by the male line from the founder of the monarchy; and the *Curacas*, the caciques of the conquered nations, and their descendants. The Incas were divided into different lineages, according to the member of the royal dynasty from whom they were descended; and as polygamy was freely indulged in, this class of nobility came in time to be very numerous. They were distinguished by a peculiar dress, and enjoyed many important and exclusive privileges. They filled every high place of trust and emolument,—the government of provinces, the command of armies,—and were alone admissible to the great offices of the priesthood. The Curacas were usually continued in their places by the government, and were possessed of more or less power according to the extent of their territory and the number of their vassals, subject, however, to the jurisdiction of the great provincial governors. They were required occasionally to visit the capital, and to allow their sons to be educated there as pledges of their loyalty. The object of war with the Incas was to extend the worship of the sun, and to confer upon the conquered nations the blessings of such a civilization as they themselves enjoyed; and hence their contests were not carried on in a bloodthirsty or rapa-

Peru.

cious spirit, and the conquered nation was immediately on submission admitted to the full enjoyment of all the privileges of the natural subjects of the Inca.

The empire was divided into four great provinces, each under a viceroy or governor, who was assisted in his administration by one or more councils for the different departments. These viceroys resided for at least a portion of their time in the capital, where they constituted a sort of council of state to the Inca. The nation was further divided into bodies of 10, 50, 100, 500, 1000, and 10,000 inhabitants, each of which was under the authority and supervision of a responsible officer. The laws were few and exceedingly severe. There was no appeal from one court to another; but visitors patrolled the kingdom at certain times to examine into the conduct of the judges and magistrates, to hear complaints, and to report any neglect or violation of duty.

The whole land of the empire was divided into three parts,—one for the sun, another for the Inca, and the last for the people. The lands assigned to the sun furnished a revenue to support the temples and maintain the costly ceremony of Peruvian worship and the multitudinous priesthood. Those reserved for the Inca went to support the royal state, and to supply the various exigencies of the government. The remainder of the lands were divided, *per capita*, in equal shares among the people. This division of the soil was renewed every year, and the possessions of the people were increased or diminished according to the number of their families. The whole territory, however, was cultivated by the people. The lands belonging to the sun had to be first attended to; then those of the widows, orphans, sick, &c.; then their own; and lastly those of the Inca. The immense flocks of sheep scattered over the various provinces belonged exclusively to the sun and the Inca. They were entrusted to the care of experienced shepherds, and regulations for their management prescribed with the greatest minuteness, and with a sagacity that excited the admiration of the Spaniards, who were familiar with the management of sheep in their own country. At the appointed season they were all sheared, and the wool deposited in the public magazines, whence it was dealt out to each family according to its wants. Care was taken that each household should employ the materials furnished for its own use in the manner that was intended, so that no one should be unprovided with the necessary apparel. All the mines belonged to the Inca, and were wrought exclusively for his behoof by persons familiar with this service. A small portion of the community was instructed in the mechanical arts. The nature and amount of service required of every individual was prescribed by law, and was so regulated with regard to the welfare of the people, that even the more wearing and unwholesome of the labours were carried on without any detriment to health. Work was provided for all, and idleness was severely punished as a crime The different employments usually descended from father to son. A part of the agricultural produce and manufactures were sent to the capital, but the greater portion was stored in magazines scattered over the different provinces, where there was frequently a supply of grain that would last for several years; and thus seasons of scarcity were provided for, and relief furnished to those whom sickness or misfortune had reduced to poverty. There were no poor in the land. An account was kept of the births and deaths in the various districts throughout the country, and exact returns of the actual population made to the government every year. At certain intervals, also, a general survey of the country was made as to its soil, fertility, products, &c.

The Peruvians believed in the existence of one great Supreme Being, the creator of the world, whom they called Pachacamac (from *camac*, creator, and *pacha*, world). No temple was raised to this invisible being, save one only in the valley, which took its name from the deity himself, not far from the Spanish city of Lima. Subordinate to Pachacamac, but endowed with intercessory power, was the sun, the deity whose worship they specially inculcated, and whose temple rose in every city and almost every village throughout the land It was he who presided over the destinies of man, gave light and warmth to the world,—the founder of their empire, and the father of their royal dynasty. Besides the sun, the Incas acknowledged other objects of worship, as the moon his sister-wife, and the stars; while among their subjects, the earth, wind, rain, thunder, as well as mountains, rivers, &c., received divine honours. They also admitted among their gods the numerous deities of the conquered nations. The sacerdotal order was very numerous. At the head of all was the high priest, or *Villac Vma*, who was second only to the Inca in dignity, and was usually chosen from his brothers or near kindred. He was appointed by the monarch, and held office for life; and he in turn appointed to all the offices under him. The duties of the priest were confined to ministrations in the temple, and his science was limited to an acquaintance with the fasts and festivals of his religion, which were very numerous, and their rites very complex and elaborate. Their sacrifices consisted of animals, grains, flowers, &c.; and we would fain believe that Garcilasso, an Inca by birth, is correct in asserting that "no human victim was ever offered in the Temple of the Sun," or permitted in worship,—though this is expressly contradicted by most of the Spanish writers. On the death of an Inca, however, a number of his attendants and favourite concubines, amounting sometimes, it is said, to a thousand, were immolated on his tomb. Marriage was a ceremony performed once a year by the Inca among his own kindred, and by the Curacas and governors in their various districts. The nobles, like their sovereigns, were allowed a plurality of wives; but the people generally, whether by law or necessity, were limited to one.

In looking at the ancient Peruvians, one is in doubt whether the knowledge they display in some respects, or their ignorance in others, is the more remarkable. In looking at their government, we can scarcely conceive of anything more suitable for a people in their condition. Though despotic in its nature, it was eminently patriarchal; every one, from the highest to the lowest, being made to feel his dependence upon it in every act of his life. Poverty and idleness, the two great causes of dissatisfaction in a people, were carefully guarded against. No one could be poor, neither could any one become rich; for, however industrious, he could not add one rood to his possessions, nor advance himself one hair's-breadth in the social scale. All might enjoy, and did enjoy, a competence; and ambition and avarice found no place in the breast of the Peruvian. No despotic system of government was ever devised more suited for its object than was this one. It contributed not a little to the security of the empire, that under the sovereign there was an order of hereditary nobles of the same divine origin with himself, and immeasurably above the rest of the people. They thus received implicit deference from the multitude, while, from long training, they became ready and expert agents in carrying out the measures of government. It is not a little remarkable that, while in government, in morals, and in some of the mechanical arts, they had made such advances, in all that more properly belongs to intellectual culture they were extremely ignorant. They possessed no written language, but used as a substitute an instrument called a *quipu*. This was a cord about two feet long, composed of different coloured threads tightly twisted together, from which a quantity of smaller threads were suspended in the manner of a fringe. The colour of the threads represented various objects, the number of which was indicated by knots. Such was the imperfect substitute for writing, and in this way the annals of their country were handed down from generation to generation. They had no species of money, and carried on no commerce. Their knowledge of astronomy was very imperfect, which is the more remarkable, seeing that the celestial bodies were the chief of their deities. In this respect they were far behind the ancient Mexicans. (See farther on the civilisation of ancient Peru, Prescott's *History of the Conquest of Peru*, and the various works therein cited.)

History.

The first distinct information received by the Spaniards of the existence of Peru was about the year 1511. Vasco Nuñez de Balboa, then governor of the small colony of Santa Maria in Darien, made frequent incursions into the neighbouring country; and on one of these occasions a dispute having arisen amongst the Spaniards about the division of some gold, a young cacique who was present struck the scales with his fist, and scattered the precious metal, exclaiming, "If this is what you prize so much that you are willing to leave your distant homes, and risk even life itself for it, I can tell you of a land where they eat and drink out of golden vessels, and gold is as cheap as iron is with you." The eager cupidity of the Spaniards was roused by this information, and no time was lost in preparing for the invasion of this land of gold. Balboa, accompanied by a hundred and ninety of his countrymen, and about a thousand Indians, commenced his journey across the isthmus, which, although not more than sixty miles in breadth, presented so many obstacles that five-and-twenty days were spent before he obtained a sight of the Pacific Ocean. Armed with sword and buckler, he rushed into its waters, and cried out that "he claimed this unknown sea, with all that it contained, for the King of Castile, and that he would make good the claim against all Christians or infidels who dared to gainsay it." This spot he designated the Gulf of St Michael, a name which it still bears; and here he obtained more explicit information respecting the Peruvian empire. But though he extended his discoveries some twenty leagues farther south, he was not destined to accomplish his object; for, having returned for reinforcements, he was superseded in his command by an ungrateful government, and although afterwards restored to high authority, he soon fell a victim to the jealousy of the individual with whom he was associated in the government.

It was some time after this before any farther attempts were made to discover Peru; but in 1519 the capital of the colony was transferred from the shore of the Atlantic across the isthmus to the ancient site of Panama, on the Pacific, some distance east of the

present city, as being more suitable for prosecuting discoveries in that region. In 1524 an expedition was fitted out, at the head of which was Francisco Pizarro, the natural son of a gentleman of family, but himself totally uneducated, and doomed to spend the early part of his career as a swine-herd. He subsequently entered the army, and being of a daring spirit, and endowed with a robust frame of body, he was foremost in every danger, and able to endure the greatest fatigue. Such qualities soon brought him into notice; and he was found to be possessed of others of a higher order, fitting him to command as well as to serve Thus, while a favourite with the soldiery, his superiors saw in him a man eminently fitted for carrying out their more difficult and dangerous enterprises, and the success that attended him on such occasions speedily raised him to an eminent position. He was one of those that had accompanied Balboa on the previous expedition, and gained the esteem of that general; and he subsequently distinguished himself in the wars in the north. Associated with him on the present occasion were Diego de Almagro, a man of like mean birth with himself, but a gallant and brave soldier, and Hernando de Luque, an ecclesiastic, who acted as priest and schoolmaster at Panama. The last of these was to contribute principally to the expenses of the expedition, while the others were to give their labour and experience, with what small funds they had. A vessel was speedily got ready, and Pizarro set sail from the port of Panama about the middle of November 1524, with little more than a hundred men, Almagro being to follow in a second vessel of inferior size, as soon as it could be fitted out. The season of the year was the most unsuitable for the enterprise, for the periodical winds which then set in were directly adverse to the course which he proposed to steer. He touched at several places on the coast, but found the country everywhere of the same uninviting character,—the low grounds covered with swamps and marshes, and the high lands overgrown with impenetrable forests. In seventy days they had reached no farther south than Punta Quemada, and a fierce engagement with the natives here, in which they had two killed and many wounded, at length determined them to return for assistance. By this time famine, disease, and encounters with the natives had reduced their numbers by more than a fifth. Almagro had in the meantime fitted out another vessel, and set sail from Panama with about seventy men. He reached Pueblo Quemada in a much shorter time than Pizarro had done, and was received in the same hostile manner by the natives, whom, however, he vanquished, burning their town, and forcing the inhabitants to take refuge in the forests. This victory, however, cost him dear, for by a wound received in the encounter he lost one of his eyes. He pursued his voyage, touching at several places on the coast, till he reached the mouth of the Rio de San Juan, about 4. N. Lat. He here met with a higher state of civilization than he had yet seen,—neat cottages and cultivated fields; but his mind was by this time filled with anxious thoughts regarding Pizarro, having seen no traces of him beyond Quemada, and he resolved to return. Touching at the Pearl Islands, he learned that his colleague was at Chicama, a place on the mainland at a short distance from Panama. Here the two adventurers met; and after recounting each other's exploits and escapes, they consulted regarding their future operations. It was at length resolved that Almagro should proceed to Panama to raise the necessary supplies, while Pizarro was to remain in his present quarters. The former, however, met with considerable difficulty in the execution of his mission, for the governor Pedrarias declared against the expedition, and was only after a time gained over by the intercession of Hernando de Luque. The three colleagues now entered into a contract, by which the whole of the conquered territory and spoils were to be divided equally among them, —Hernando having advanced as his share of the enterprise 20,000 *pesos* of gold, a sum estimated at about L.50,000 of our money. Two larger vessels were now purchased, and stores laid in; but it was with the greatest difficulty that they could muster a force of 160 men. They at length set sail, each in his own vessel, and accompanied by an experienced pilot named Ruiz. In a short time they arrived at the mouth of the Rio de San Juan, where Pizarro succeeded in surprising a small village, and carrying off a considerable booty in gold, together with a few of the natives. They now saw the necessity of having a stronger force to cope with the increasing population of the country; and accordingly it was decided that Almagro should return to Panama with the treasure, and beat up for reinforcements, while Ruiz, in the other vessel, should reconnoitre the country towards the south, and Pizarro, with the rest of the force, remain in the neighbourhood of the river. Ruiz proceeded as far south as Punta de Pasado, about half a degree beyond the equator, and returned, after an absence of several weeks, to the spot where he had left Pizarro and his comrades. The latter had just returned from a long incursion into the interior, where he had undergone great hardships and lost not a few of his companions. Almagro sailed into port soon after with his vessel laden with a fresh supply of stores, and bringing with him a considerable number of volunteers. With renewed spirits they proceeded on their journey; but by this time the favourable season had passed, and they were long tossed about before they reached the Island of Gallo. Proceeding still southward, they found the country more and more populous, and the evidences of civilization to increase; and when they anchored off the port of Tacamez they saw before them a town of 2000 or more houses laid out into streets, and containing a numerous population. Further reinforcements were again necessary; and it was agreed that Almagro should return to Panama, Pizarro and the rest remaining at Gallo. With Almagro, however, came news to Panama of the deplorable condition of the party; so that the governor not only refused to countenance any further attempts, but despatched two vessels to bring home Pizarro and his companions. While most of the latter gladly embraced the opportunity of getting away, Pizarro and thirteen others sternly refused to return. These were accordingly left on the island, and they subsequently removed to the uninhabited island of Gorgona, about 25 leagues farther north, and 5 leagues from the continent. The governor filled with indignation when he heard of the obstinacy of Pizarro and his followers, and sternly refused to render any assistance to men thus bent on their own destruction. At length, however, he was so far overcome by the arguments and entreaties of Almagro and De Luque that he consented to another vessel being sent to Pizarro, but with no more hands than were necessary to work her, and with express orders to Pizarro to return within six months. Though disappointed that it brought no additional recruits, Pizarro yet gladly welcomed the little vessel, having been by this time seven months on the island. In twenty days after leaving Gorgona, the adventurous vessel rounded the point of St Helena, and glided smoothly into the Gulf of Guayaquil, anchoring off the island of Santa Clara, at the entrance of the Bay of Tumbez. Here they beheld a town of considerable size, with many buildings apparently of stone and plaster. The people collected along the shore, and friendly relations were exchanged between them and the Spaniards. Here the latter had their golden dreams, if possible, more than realized; but for the present they could only feast their eyes on the riches before them. To attack the place with his handful of followers Pizarro saw to be useless; and accordingly he took a friendly leave of the natives, promising soon to return. He continued his progress southward; and everywhere received the like friendly welcome from the natives, and gathered information of the wealth and magnitude of the empire of Peru. He proceeded to about the ninth degree of south latitude; and having by this time seen enough to convince him of the value of his discovery, he turned his prow northward, and sailed for Panama. In his way he touched at Tumbez, where some of his followers were at their request left, and two or three Peruvians were taken on board. The excitement caused by their arrival at Panama was very great; but still the coldness of the governor held out to them but little hopes of efficient help being obtained from that quarter, and it was resolved to apply to the crown itself. Pizarro was accordingly sent to the mother-country, and reached Seville early in the summer of 1528. He was graciously received by the emperor Charles V., and was invested with supreme civil and military authority over the country to be conquered, for 200 leagues south of Santiago. Pizarro, on his part, engaged to raise 250 men, with the requisite vessels and stores for the conquest of the country within six months. He could scarcely, however, raise half this body of men, and had to steal privately out of the port of Seville, in order to avoid the scrutiny of the officers of government. He was accompanied by four brothers, three of whom were illegitimate like himself,—Francisco Martin de Alcantara on the mother's side, and Juan and Gonzalo Pizarro on the father's. The legitimate brother was named Hernando. At Nombre de Dios, Pizarro was met by his two associates, and great was Almagro's wrath to find that all the chief offices had been conferred upon his colleague. A reconciliation, however, was at length effected; and early in January 1531 the expedition, consisting of 180 men, with 27 horses for the cavalry, left Panama in three vessels, Almagro remaining behind, in order to collect reinforcements. Having encountered contrary winds, they had in thirteen days only reached St Matthew's Bay. Here it was resolved to disembark the troops, who would advance along the coast while the ships held on their course at a convenient distance from the shore. In the province of Coaque they suddenly fell upon a town, and obtained a valuable booty in gold, silver, and precious stones. A large quantity of this was sent to Panama with the ships, while the troops continued their march southwards. At Puerto Viejo they were joined by a reinforcement of thirty men, under an officer named Benalcazar. While at Puna, an island on the Gulf of Guayaquil, which they had treacherously taken possession of, notwithstanding the friendly reception they had met with from the natives, they received a further reinforcement of 100 men in two vessels; and Pizarro now con-

sidered himself in a position to enter upon the proper theatre of his labours. He accordingly passed over to Tumbez, and there learned that the country had been for some time distracted by a civil war between two sons of the late monarch.

Huayna Capac was the reigning Inca at the time when the Spaniards first visited the coast of Peru. He is represented as a prince distinguished both in peace and war. He brought under the sway of the Incas the powerful state of Quito, and reduced to subjection many of the independent tribes on the remote borders of his territory. He likewise pursued an enlightened policy towards his subjects, encouraging agriculture and other branches of industry, opening up new roads, and introducing the civilization of the Incas among the conquered nations. He is said to have been deeply impressed with the accounts brought to him of the white men. He saw in their ships and weapons indications of a civilization far superior to that of his own people; and he feared that at no distant day they would return, and might shake to its foundations the mighty empire of the Incas. Oracles, too, had darkly predicted mighty events that were to happen on the death of the twelfth Inca; nor were omens wanting—those powerful preachers to the untutored mind. Huayna Capac died about 1529, leaving his kingdom of Peru to his eldest son Huascar, but Quito he left to his favourite son Atahuallpa, by a daughter of the conquered monarch. The two sons, however, did not long rest contented with their respective possessions, and a civil war was the consequence. Victory at length declared for Atahuallpa; and in order to seat himself more firmly on the throne, he put to death all the descendants of the late Inca that he could seize either by stratagem or force. The life of Huascar, however, was, for political purposes, spared in the meantime; but he was detained a close prisoner. These events occurred in the early part of 1532, and completely diverted the attention of the Peruvians from the circumstance of a foreign invader having landed on their soil. Pizarro at once saw the importance to him and his cause of this state of the country. After some time spent in reconnoitring the country, he fixed upon a spot in the rich valley of Tangarala as a site for a settlement. Hither accordingly the Spaniards removed and set about building a town, to which they gave the name of San Miguel. Pizarro here learned that the victorious Atahuallpa lay encamped about ten or twelve days' journey off, and though his entire force would not amount to 200 men after leaving 50 for the protection of his new settlement, he resolved to set out to meet the Inca. On the 24th of September 1532, therefore, he marched out of San Miguel at the head of his small body of adventurers, amounting in all to 177 men, of whom 67 were cavalry. Everywhere the people received them with confiding hospitality, and as yet the Spaniards saw it to be their interest to reciprocate their friendships. At length they arrived at Caxamalca, within a league of the Peruvian encampment, and here they saw the slope of the hills white with pavilions as thick as snow-flakes for the space apparently of several miles. The sight caused something like fear in the stoutest bosom; but it was now too late to draw back. In the afternoon of the 15th of November 1532, the Spaniards reached Caxamalca, which had been vacated by the inhabitants for their reception, and immediately they sent an embassy to the Inca inviting him to visit them in their new quarters. They were graciously received by the Inca, and he promised to pay them a visit on the following day. The reception prepared for the Inca was such as he little expected when he set out with an unarmed retinue to redeem his promise. He was borne on the shoulders of his principal attendants seated on a throne or couch resplendent with plates of gold and silver, enriched with precious stones, and adorned with waving plumes of the most gorgeous hues. When he entered the plaza or great square of the town, a dominican friar, Fray Vicente de Valverde, came forward with his breviary, or, according to other accounts, a Bible in one hand and a crucifix in the other, and, approaching the Inca, expounded to him the doctrines of the Christian religion, exhorting him to embrace the true faith, and to acknowledge himself a vassal of the Spanish crown. Enraged and astonished at this extraordinary proceeding, the Inca demanded by what authority he said these things. The friar handed him the book which he held in his hand. "This," said he, holding it to his ear for a moment, "tells me nothing," and dashed it to the ground with disdain. The monk immediately ran towards Pizarro, calling out that the Christian religion had been dishonoured, and at a given signal the Spaniards who had been concealed in the adjoining buildings rushed out upon the defenceless natives. The slaughter was immense on the side of the Indians; and the murderous nature of the attack may be gathered from the fact, that not a single Spaniard was killed or wounded with the exception of Pizarro, who received a slight wound on the hand from one of his own men. Atahuallpa himself was taken prisoner; and a rich booty was found in the Peruvian camp, consisting of gold and silver, precious stones, cotton, and woollen stuffs, &c. The captive monarch, though receiving every attention at the hand of Pizarro, naturally felt anxious to regain his liberty. He feared also that the news of his captivity might reach Huascar, who, by corrupting his keepers, might obtain his liberty, and would find little difficulty in putting himself at the head of the empire. The love of gold, he soon learned, was the prime motive that had brought the Spaniards into the country; and as the price of his liberty, he offered to Pizarro to fill the room in which they stood with gold as high as he could reach. This room is said to have been 22 feet long by 17 feet wide, and the height 9 feet from the floor. Pizarro, charmed with the idea of so much gold, and knowing how easy a matter it was to break faith with a captive, readily entered into the agreement, and the terms of it were duly drawn up by a notary. Atahuallpa therefore, with all haste, despatched couriers to Cuzco and all the principal places of the kingdom, with orders to forward the gold utensils and ornaments of the palaces, temples, &c., to Caxamalca without delay. In the meantime, the Spaniards remained in Caxamalca unmolested, and small detachments of their number marched into the remoter provinces, and were everywhere received with marks of the most submissive respect. News having by this time reached Huascar of the Inca's captivity and of his offered ransom, he is said to have offered to the Spaniards a much greater amount if they would restore to him his dominions, of which he had been unjustly deprived. Atahuallpa was greatly alarmed on hearing of this, and fearing lest the Spaniards might listen to his brother's request, he caused him to be assassinated. Meanwhile Indians were daily arriving at Caxamalca loaded with treasure; and at this time, too, arrived Almagro, with a strong reinforcement of 150 foot and 50 horse. This was about the middle of February 1533, and now Pizarro found himself in a position to go forward with the conquest of the country. The whole of the Inca's ransom, however, had not yet arrived; but at length they agreed to accept what had already arrived in full of the obligation. The total amount of gold, when melted down, was found to be 1,326,539 *pesos de oro*, equivalent to about L.3,500,000 sterling. Besides this there were a number of articles of very delicate workmanship, which were reserved for being sent as a present to the emperor. After deducting one-fifth for the crown, the rest was divided in certain proportions among the troops, Pizarro himself and his officers receiving sums in proportion to their rank. Considerable difficulty was experienced in dealing with Almagro's followers, who demanded to share in the spoil, but at length they agreed to resign all claim on being paid a stipulated sum. Nothing in this division is said of Almagro, who in terms of the original contract was entitled to an equal share with Pizarro himself. Luque, indeed, was no longer to be benefited by worldly treasure, having died a short time before Almagro's last departure from Panama—too soon to learn the full success of the enterprise which, but for his exertions, must have failed. After dividing the spoil, it came to be considered what was to be done with the Inca, who now became clamorous for his liberty. Rumours of a rising among the natives now began to be current, and though they seem to have had no foundation in fact, they yet served to give colour to a proceeding which would get them over their difficulty with the Inca. This was nothing less than the putting him to death. A ceremony preparatory to execution was gone through (it cannot be called a *trial*), and he was sentenced to be burned alive in the great square of Caxamalca that very night. When bound to the stake, Father Valverde made a last attempt to induce him to adopt the Christian faith and be baptized, promising that if he did so he would receive the less painful death of garrotting. On being assured by Pizarro that such would be the case, he consented to abjure his own religion and be baptized; and accordingly he suffered by the latter mode on 29th August 1533. Thus perished by an ignominious death the last of the Inca monarchs of Peru.

On the death of Atahuallpa, Pizarro invested a son, or, according to others, a brother of that monarch, with the insignia of royalty, hoping that a young man without experience might prove a more passive instrument in his hands than an ambitious monarch who had been accustomed to command; but the young prince did not live many weeks to enjoy his new dignity, and no one was substituted in his place. At Cuzco a brother of Huascar, named Manco Capac, was elevated to the throne. Early in September the Spaniards, now amounting to almost 500 men, of whom nearly one-third were cavalry, set out from Caxamalca for the capital. Pizarro halted for some time at Xauxa, in order to found there a Spanish colony, judging it a favourable position for keeping the natives in check; while at the same time it afforded an easy communication with the sea coast. Though during this march bodies of Indians were seen hovering about at a distance, yet they had offered no actual resistance. A detachment of sixty horse, however, under De Soto, having been sent forward to reconnoitre the country in advance, were attacked by a body of the natives, who fought with great fury, and the issue was doubtful, till the arrival of Almagro with a reinforcement of cavalry struck terror into the

natives, and prevented them from renewing the contest. Pizarro at length set out from Xauxa, leaving his treasures there under a guard of forty men; and nothing of importance occurred on the road till he reached the vale of Xaquixaguama, about 5 leagues from Cuzco. Here he halted for several days, and one of his first acts was the execution of Challcuchima, one of the ablest of the Peruvian generals. He had attended his royal master during his captivity, and since his death he had remained in the Spanish camp. He was now accused of having stirred up the natives against the Spaniards, and was sentenced to be burned alive. When at the stake he coldly replied to Father Valverde's entreaties to adopt the Christian faith, that he "did not understand the religion of the white men." Soon after this Manco Capac arrived in great state at the Spanish camp, and, announcing his title to the throne, claimed the protection of the white men. He was received with great cordiality, and assured that they had come into the country in order to vindicate the claims of Huascar to the throne, and to punish the usurpation of his rival. Taking with him the Indian prince, Pizarro now resumed his march, and on the 15th November 1533 entered the Peruvian capital. This city far surpassed anything that they had yet seen in the New World. The beauty of its edifices, the length and regularity of its streets, and the appearance of comfort, or even luxury, visible in its numerous population, excited their astonishment. The population of the city itself is said to have amounted to 200,000, and that of the suburbs to as many more. Though doubtless the inhabitants had concealed much of their treasures, yet the gold obtained here is said to have even exceeded that received as the ransom of the Inca. One of the first acts of Pizarro, after dividing the spoil, was to place Manco on the throne, in order to give his acts some air of authority with the natives. He afterwards organized a municipal government, and induced his soldiers to settle in the place by liberal grants of houses and land. In March 1534 a Spanish force, amounting to 500 men, under Don Pedro de Alvarado, a general who had greatly distinguished himself in the Mexican war, arrived in the Bay of Caraques. He had come to take possession of Quito, which he believed, or pretended to believe, was not included in Pizarro's territory. Almagro was immediately despatched to meet the invaders, and came upon them in the plains of Riobamba. By this time Alvarado's army had been reduced by more than a fourth, in consequence of the great hardships they had undergone on their march; so that they were little inclined to enter upon a contest which it was Almagro's interest to avoid. Negotiations were accordingly commenced, and at length Alvarado agreed to hand over his fleet, forces, and stores, to Pizarro for 100,000 *pesos de oro*.

Cuzco being found to be unsuitable as the capital of the colony, it was resolved to build another near the coast; and accordingly, on the 6th January 1535, the new capital was founded in the valley of Rimac. It was first named *Ciudad de los Reyes*, or "City of the Kings;" but subsequently it came to be called Lima. The Spaniards applied themselves with vigour to the task of building the new city, under the eye of their chief. In the meantime, Almagro had arrived at Cuzco and taken command of that capital, and here he received intelligence of the return of Hernando Pizarro from the court of Spain. This time he had taken the precaution to send a secret messenger of his own along with Hernando, to look after his interests at court; and he now learned that he had received a grant of all the country lying south of the southern limit of Pizarro's territory. Almagro was greatly elated at these tidings, and immediately laid claim to Cuzco as being within the bounds of his territory. He accordingly proceeded to exert his independent authority, and matters were approaching an open rupture when Pizarro himself appeared among them. He managed to appease his rival; and Almagro agreed to waive his claim to the capital in the meantime, and set out on the conquest of Chile. Pizarro now returned to the coast, and had the satisfaction of seeing his new capital rapidly advancing.

Manco Capac, who had hitherto so tamely submitted to be a tool of the Spaniards, was nevertheless a person of some spirit and courage; and at length, exasperated by the repeated indignities to which he was exposed, he effected his escape from Cuzco, where he then was. A rising among the natives immediately followed, and Cuzco was besieged in February 1536 by a force amounting, it is said, to 200,000 men. To add to the distress of the Spaniards, their city was set on fire by the burning arrows and red-hot stones of the natives, and more than one-half of it was reduced to ashes. They frequently sallied out of the town, but beyond killing a number of the natives, they effected no advantage, while the natives increased in skill and bravery with each contest. They however succeeded in taking possession of a fortress overlooking the city, but Juan Pizarro lost his life in the struggle. Month after month passed away, and still there came no relief. Indeed the rising had been general. Several hundred of the Spaniards living upon their estates had been massacred; Xauxa was besieged; and a strong force had attempted to besiege Lima, but were put to flight. Several detachments had been sent by the governor to relieve Cuzco, but they were all cut off by the natives. In this dilemma, Pizarro sent letters to the governors of Panama, Nicaragua, Guatemala, and Mexico, imploring them for assistance.

The siege of Cuzco had now lasted more than five months, and as the season of planting had come on, Manco, fearing a famine, sent the greater part of his followers home, with orders to return and renew the blockade as soon as their field labours were over. The Spaniards beheld with joy their enemies melting away; but a new cause of dread appears in the person of Almagro. He had proceeded as far south as the vale of Coquimbo, about 30. S. Lat., but found nothing to induce him to remain; and his men, who had suffered many hardships on the way, now became clamorous for his return. On reaching Arequipa, he learned of the revolt of the Indians, and hastened forward to Cuzco. He now renewed his claim to that city, and sent an embassy to the municipality requiring them to recognise him as their lawful governor. A truce was, however, concluded in the meantime; but Almagro, hearing that a strong body of troops were marching from Lima towards Cuzco, suddenly took possession of the capital, and the two Pizarros were made prisoners. He then set out to meet the force from Lima, at this time lying at Xauxa. The two armies came in sight of each other at the Rio de Abancay. Aided by the treachery of one of the officers of the opposite army, Almagro forced the river during the night, and obtained an easy victory, on the 12th July 1537, and took the commander Alonzo de Alvarado prisoner. He now returned in triumph to Cuzco.

Meanwhile aid began to reach Lima, and Pizarro was soon able to set out for Cuzco at the head of 450 men, most of whom were cavalry. On his way, he heard of the arrival of Almagro and of the defeat of Alvarado, and immediately he returned with all haste to Lima, to put himself in a position for defence, judging, not incorrectly, that Almagro might also lay claim to that city. The latter having now obtained possession of Cuzco, was easily persuaded by his restless followers that Lima also fell within his territory. He accordingly set out for that city, and on the way heard of the escape from Cuzco of Gonsalo Pizarro, Alvarado, and other prisoners, and of their arrival in Pizarro's camp,—Hernando Pizarro he had taken along with him. Pizarro now attempted to negotiate; and at length it was agreed to wait for definite instructions from Castile, Almagro meanwhile remaining in possession of Cuzco, while Hernando Pizarro was to be set at liberty under promise to leave the country within six weeks. During the time that negotiations were pending, Pizarro was busily engaged in warlike preparations, and when his brother was set at liberty, he found himself in a condition to unmask his intentions. Almagro, on seeing that he had been deceived, immediately made for his capital; and a council of war being held, it was resolved to wait the arrival of the enemy at Las Salinas, a place within a league of Cuzco. Almagro, himself at this time too ill to take the command of his troops, devolved it upon Orgoñez, the ablest of his generals. Pizarro had intrusted the command of his forces to his two brothers, and returned to Lima. Almagro's force amounted to about 500 men, while that of the enemy was about 200 more. The fight took place on 26th June 1538, and for some time raged with great fury, but at length Orgoñez being slain, and his troops thrown into confusion, victory declared for the Pizarros. Hernando now took possession of Cuzco, which he gave up to pillage. Almagro was taken prisoner, and thrown into irons, and shortly after, this brave man and able soldier was condemned and executed.

Pizarro, on learning of the victory of Las Salinas, immediately set out for Cuzco, but waited for some time at Xauxa, it is said, till he should hear of the execution of Almagro. He then entered the city in great state; and his conduct now showed that he considered himself the undisputed possessor of all this vast kingdom. Instead of attempting to conciliate Almagro's party, he treated them with undisguised contempt; while many of his own adherents he disgusted by his haughty bearing, and by the manner in which he appropriated to himself, or bestowed on his brothers and favourites, all the most valuable districts of the country. But the time had not yet come for a revolt. The country being now in apparent peace, Hernando prepared to revisit Spain, and accordingly embarked at Lima in the summer of 1539, earnestly counselling his brother to beware of the Chile men, as Almagro's followers were called. Not a few of these, however, were already in Spain, and the reception of Hernando in that country was colder than he had expected. Indeed the clamours against him became so great, that he was at length cast into prison. He lay there for twenty years, and when at length, in 1560, he was released, he was an old man, bent down by years and infirmities; but he still survived for several years, an object of pity rather than of indignation.

The state of Peru was now such as to demand the immediate in-

terposition of government; but the mission was one of extreme difficulty, for Pizarro's power was now firmly established over the country, and he would not readily submit to any interference with his authority. At length Licentiate Vaca de Castro, a member of the Royal Audiencia of Valladolid, was selected for this delicate mission. He was to appear before Pizarro in the capacity of a royal judge, to consult with him on the redress of grievances, especially with reference to the natives, to transmit an account of the state of the country to the court at Castile, and, in the event of Pizarro's death, to take upon himself the government of the country. The last provision was, as the result showed, necessary, for before he reached his destination Pizarro had fallen by the hand of assassins.

Almagro had left a son by an Indian woman, and had named him his successor. This young man, on the imprisonment of his father, was sent to Lima, where he continued to live, and his house became the resort of the disaffected of his father's followers. A number of the more desperate of these, goaded on by poverty, and the insults to which they were continually subjected, at length resolved on the assassination of the governor, who was now in Lima. Pizarro himself seems to have been singularly blind to his danger, and notwithstanding numerous cautions that he received, he took no precautions for his safety. On the 26th of June 1541, the conspirators, to the number of eighteen or twenty, sallied out from Almagro's house, headed by Juan de Herrada, shouting "Long live the king; death to the tyrant." They gained the palace without opposition, and reached the apartment where their victim was conversing with some friends, having just risen from table. Hastily enveloping one arm in his cloak, and seizing a sword, he maintained for some time the unequal contest; but at length he received a deadly thrust in the throat, and fell to the ground, when he was immediately despatched. Thus perished the man who had acquired for Spain the richest of her possessions,—a man possessed of great abilities, and adorned with many excellent qualities, but whose perfidy and cruelty have left a stain upon his character that, however much it may be extenuated by the circumstances of his early life, and the times in which he lived, can never be removed. With him fell his half brother Martinez de Alcantara.

On the death of Pizarro, the young Almagro was placed at the head of the government, but his authority was only tardily acknowledged in places at a distance from Lima. Gonzalo Pizarro, who had been appointed governor of Quito, was at this time away on an expedition into the country lying eastward of the Andes. Vaca de Castro meanwhile received the news of the death of Pizarro at Popayan. He continued his march to Quito, where he was well received by Gonzalo's lieutenant, and he now produced his royal commission to assume the government. Emissaries were despatched to the principal towns, requiring their submission, while Castro himself continued [illegible] slowly towards the south. Almagro meanwhile had proceeded to Cuzco, where he learned of the arrival of Castro at Lima. Resolved to try the effects of negotiation before an appeal to arms, he sent an embassy to the new governor, stating that he did not dispute his authority over Peru, and that he had only taken up arms to secure possession of the territory bequeathed to him by his father, of which he had been unjustly deprived by Pizarro. To this he received no answer; and thus saw that his only recourse was to arms. He accordingly left Cuzco about midsummer 1542, at the head of a well-disciplined and well-appointed force of about 500 men. Castro had by this time set out from Lima, and on reaching Xauxa, found himself with an army of about 700 men; but they were not so well disciplined or armed as those of Almagro. The two armies met in the plains of Chupas, and the battle took place on the 16th September 1542. Both sides fought with great bravery, and the victory was long doubtful, but at length it declared for Castro. Almagro, by his feats of valour, showed himself not unworthy of his father's name; but when all was lost, he fled with a few followers to Cuzco, where he was taken prisoner, condemned, and executed. He met his fate with the utmost composure, made no appeal for mercy, and only requested that his bones might be laid by the side of his father's.

Vaca de Castro having now got rid of his rival, gave his attention to the settlement of the country. He laid down laws for its better government, and attempted to ameliorate the condition of the natives by in some measure protecting them from the unjust exactions of their conquerors, and by establishing schools for teaching them Christianity. But while these gradual measures were being carried out in Peru, one of a much more sweeping nature was resolved upon in Spain. This was nothing less than the proclamation of all the Indians vassals of the crown of Spain, and thus only to be employed in voluntary labour, for which they were to receive a fair remuneration. Slaves were declared to be free on the death of their present proprietors; but all those held by persons in public offices, ecclesiastics, or persons criminally concerned in the feuds of Almagro and Pizarro, were to be immediately set at liberty. To carry out this measure, Blasco Nuñez Vela was appointed governor of Peru, with the title of Viceroy. A royal audience, consisting of four judges, was also named to assist him in administering the law. The news of this caused the greatest indignation in Peru, and it was with difficulty that the governor could prevail upon the people to wait the arrival of the viceroy, and try the effect of pacific measures.

The viceroy reached Tumbez on the 4th March 1544, and immediately showed his determination to act up to his instructions by liberating a number of slaves. The country was now in the greatest consternation, and all eyes were turned towards Gonzalo Pizarro, the last in the land of that family who had led the armies of the conquest, and the one most likely to afford them redress. He was invited to Cuzco, and was there invested with the title of Procurator-General of Peru. The viceroy, meanwhile, had reached Lima, where he was installed in his new office; and one of his first acts was to proclaim his determination to fulfil his commission. He, however, offered to join the colonists in a memorial to the crown, soliciting the repeal of a code which he now believed would be neither for the interests of the colony nor the crown; but in the meantime he had no warrant to suspend its execution. Gonzalo was not long in mustering a force of nearly 400 men, with whom he set out from Cuzco ostensibly for the purpose of putting down the Indians, who were a continual source of annoyance to the Spaniards. Scarcely had he left the city when he heard of the death of Manco. He had been assassinated by a party of the Almagro faction, who had taken refuge among the Indians on the defeat of their young leader, and they in their turn were all slain by the Indians. Though the alleged cause of Gonzalo's warlike preparations was thus removed, yet it had little effect upon his proceedings. His intentions being now apparent, many of his followers, shrinking from the idea of open rebellion—for loyalty was ever a crowning feature of the Spaniard—secretly withdrew from his army. On the other hand, he was joined by others less scrupulous, and several bodies of troops sent out to oppose his progress came over to his ranks; so that in a short time he found the force with which he left Cuzco nearly doubled. Among those who joined his standard at this time was Francisco de Carbajal, a distinguished soldier, but now eighty years old, and preparing to return to Spain. He was at length, however, induced by the earnest entreaties of Pizarro to join his cause, and to take command under him. The viceroy now rigorously prepared for war, but he was a man particularly ill suited for an emergency like the present. He was arrogant and domineering, while he was also weak and vacillating. His arrogance was a natural result of his weakness; and unfortunately he was weak and vacillating when he should rather have been arrogant, and arrogant when it would have been better to have been vacillating. The defections from his cause led him to be suspicious of every one about him, and of none more so than his best friends. Castro he suspected of holding communication with the enemy, and he was ordered to be placed under arrest and confined on board a vessel lying in the harbour. In the meantime, he was strengthening the fortifications of the city; but at last he resolved to abandon the capital and withdraw to Truxillo, about eighty leagues distant. The judges, however, having recently arrived at Lima, were strenuously opposed to any such measure, and disapproved of his conduct in every particular. They appealed to the citizens for support, and passed a decree that the viceroy should be arrested. He was taken prisoner in his palace, and placed in strict confinement. A provisional government was then established, and one of its first acts was to suspend the odious ordinances till instructions could be received from court. Pizarro was called upon to lay down his arms, but this he refused to do, and demanded of the judges that they ratify his appointment as governor of the country by the people. Loath as they were to lay down their newly-acquired authority, they had to submit with the best grace possible, as they were without the means of resistance. Accordingly they invited Gonzalo to assume the government; and he entered the city in great state, at the head of nearly 1200 followers, on the 28th day of October 1544. The first act of the new governor was to apprehend and punish those that had taken the most active part against him; some he condemned to death, and others he sent into banishment. His next concern was to fill all the places of trust with his own partizans.

Meanwhile the ship in which Castro was confined suddenly left the port;—that officer not caring to trust himself in the power of Pizarro, had prevailed on the captain to convey him to Panama. On his arrival in Spain, there were not wanting parties to accuse him of embezzlement, injustice, and mismanagement; and though he was at length acquitted of every charge, it was only after he had been imprisoned for twelve years that the tardy tribunal of Castile were able to pronounce a judgment. Pizarro had scarcely begun to exercise his new powers when a new enemy arose to oppose him. This was the viceroy Nuñez, whom the judges had put on board a ship under the charge of one of their number, Juan Alvarez, in

order that he might be carried to Spain. Scarcely, however, had they put to sea when Alvarez, moved either by fear or remorse, put himself and vessel into the hands of Nuñez. The latter landed at Tumbez, and immediately raised the standard of royalty. Numbers flocked to his cause, and he soon found himself at the head of a considerable army. Pizarro, alarmed at these proceedings, set out in person with a large force to attack the viceroy, who was then in San Miguel. The latter, however, did not feel himself in a position to risk a battle, and consequently retreated, first to Quito, and then to Popayan. At the latter place he was joined by Benalcazar, and now found his force to amount to about 400 men. Pizarro meanwhile, at Quito, by a feigned retreat, drew the enemy towards that city, and at length the two armies met for battle about a mile from Quito on the 18th of January 1546 Pizarro's force amounted to about 700 men; and though the enemy behaved bravely, the victory was not long doubtful. About one-third of the viceroy's troops had perished; Nuñez himself was slain; and Benalcazar had fallen, covered with wounds. Pizarro remained for some time at Quito, and then set out for his capital. He was everywhere received with the greatest demonstrations of joy, and saluted with the titles of "Liberator and Protector of the People." He was now undisputed master of Peru, and began to assume a state corresponding with his fortunes.

At home the news of these proceedings caused the greatest consternation and dismay to all classes; and the government felt the greatest difficulty in coming to a decision regarding the course to be followed. At length it was resolved to try conciliatory measures, and to send out a representative who, by arguments and politic concessions, might bring back the people to their allegiance. For this difficult mission was chosen Pedro de la Gasca, an ecclesiastic who, though bred to the church, had also distinguished himself as a soldier and a diplomatist. He was a man well qualified for the management both of affairs and men; he was possessed of great abilities, of a gentle and winning manner, with at the same time great firmness and decision of character, and of undoubted fidelity and loyalty. He received the title of President of the Royal Audience, and was placed at the head of every department in the colony, civil, military, and judicial—being, in fact, invested with all the powers of the sovereign himself. His preparations were few and simple; and he set out with a slender band of followers on 26th of May 1546. By this time Panama and Nombre de Dios were in the possession of Pizarro, guarding jealously any communication with the mother country. Little danger, however, was apprehended from the arrival of a poor ecclesiastic, without an armed force, and with hardly even a retinue to support him. Great, therefore, was the astonishment of the governors when they came to know the extent of the powers vested in Gasca. At length, by his address and the promise of pardon to all who should immediately lay down their arms, they were induced to join his cause; and on the 19th of November 1546 he obtained possession of the fleet at Panama. He now adopted a bolder policy, by publicly raising levies of men and drawing supplies from all quarters. The alacrity with which people of all classes espoused his cause showed that the ancient sentiment of loyalty still prevailed. Many deserted the standard of the usurper to rally round that of a person who was invested with lawful authority; and those who had been driven to the forests and caverns now quitted their hiding-places and joined the royalist. Meanwhile Pizarro was making every preparation for war; but as town after town, and general after general, was declaring for the royalist, he judged it safer to leave Lima and go to Arequipa. No sooner had he left Lima than that city opened its gates to the enemy. Gasca himself remained at Panama till 10th of April 1547, when he set sail with his whole fleet for Peru, and after encountering much bad weather, he reached Tumbez on the 13th of June. He was everywhere received with the greatest enthusiasm, and at length reached Xauxa, where he established his head-quarters. Pizarro had meanwhile decided to evacuate Peru and go into Chile; but the mountain passes through which his route lay were commanded by a hostile force about double his own. He hazarded a battle in the plains of Huarina on 26th of October 1547; and his men, fighting with the desperation of those who had everything to lose, at length defeated the enemy with great slaughter. Elated by this victory, he now resolved not to leave the country, and marched to Cuzco. The royalists at Xauxa were much dismayed by the news of this defeat when they were looking for an easy victory. Gasca meanwhile exerted himself to raise a large force, in order to put a speedy end to the war, and at length found himself at the head of nearly 2000 men, the largest European force that had yet assembled in Peru. The two armies met in the plain of Xaquixagua; but no sooner were they drawn up in battle array than company after company of Pizarro's troops passed over to the enemy, and no alternative was left to that commander but to yield himself a prisoner. He was tried, found guilty, and soon after executed. Thus perished the last and youngest of that remarkable family, in the forty-second year of his age. His remains were deposited side by side with those of the two Almagros. Carbajal and others of the leaders were also executed; while many more were banished, and their estates confiscated.

Gasca now devoted his attention to settling the state of the country, and to establishing the government upon a true and firm basis; by which means [illegible] the hands of his successors, and facilita[illegible] orderly government of the country. Having at length accomplished his mission, he set out for Spain in January 1550, and entered the harbour of Seville in little more than four years from the time that he had sailed from that port. He was soon after raised to a bishopric, and passed the rest of his days in the peaceful discharge of his ecclesiastical functions, honoured by his sovereign, and enjoying the admiration and respect of his countrymen. Petty disturbances continued to break out in Peru for some time after the departure of Gasca, but they shortly subsided under the wise and temperate rule of his successors, who profited by his policy and example; and finally the royal authority was as completely established in Peru as in any other portion of the Spanish colonial possessions.

In the subsequent history of Peru there occurs little of interest to the general reader till the time of the war of independence. The whole of the Spanish dominions in the New World were at first divided into two governments, one subject to the viceroy of Mexico, and the other to the viceroy of Peru. In 1718 the province of Quito was separated from Peru and annexed to New Granada, and in 1788 the provinces of La Plata, Potosi, Charcas, Chiquitos, and Paraguay were detached from Peru to form the government of Buenos Ayres. Each of these governments constituted a viceroyalty; while Guatemala, Venezuela, Caraccas, Cumana, and Chile were severally formed into distinct jurisdictions under a captain-general. In 1780 an insurrection broke out among the Indians in Peru, under Tapac Amaro, who assumed the title of Inca, but it was at length suppressed. Peru did not join in the celebrated war of independence that broke out among the Spanish possessions in South America in 1810, and it was the last to throw off the Spanish yoke. It soon became evident, however, that the expulsion of the Spaniards from Peru was necessary to the safety of the other states; and hence a combined Chilean and Buenos Ayrean army, under San Martin, laid siege to Lima in February 1821. At the same time, the fleet under the command of Lord Cochrane blockaded Callao, and it was here that that gallant officer performed one of those desperate feats of valour for which he is characterized. With the boats of his little squadron he entered the port of Callao, and under the guns of its tremendous batteries boarded, captured, and carried off one of the largest of the Spanish ships of war, with more men on board than were in all the boats that attacked it. After some months, a convention was agreed to, when Lascerna, the Spanish general, with his army, left Lima, and San Martin took possession of the city. On the 28th of July 1821 the independence of Peru was declared; and a few days afterwards San Martin was proclaimed protector. Among the first legislative acts of the protectorate was a decree declaring that the children of slaves born in Peru subsequently to the 28th of July 1821 should be free. This was followed by another abolishing the tribute, and enacting that the aborigines be thenceforth denominated Peruvians like the Creoles. On the 21st of September the fortress of Callao surrendered to the protector. The success of the patriots, however, received a check in the defeat of General Tristan. He had the command of a body of troops at Ica, and had allowed himself to be surprised, and his retreat cut off, by Canterac, who took 1000 prisoners, besides some pieces of artillery and other spoil. This reverse, however, was counteracted by the victory gained over the royalists at Pinchincha on the 24th of May 1822. The protector did not long retain his popularity; deputies were summoned; and he resigned his power into their hands on 21st of September 1822. Congress lost no time in appointing a new executive, under the title of the *Junta Gubernativa*. One of the

first acts of that assembly was to decree that San Martin should bear the title of "Founder of the Liberty of Peru;" and the thanks of the nation were likewise awarded to Lord Cochrane for his achievements in the Peruvian cause. The proceedings of the new government were marked by feebleness and discord. An unsuccessful attempt to reduce the royalists increased popular clamour against the government junta, which was at last expelled from power, and General Don Jose de la Riva Aguero was made president of the republic.

Santa Cruz, a Peruvian, who in the sequel greatly distinguished himself, assumed the chief command of the army; and it was determined in a council of war to make another effort in the Puertos Intermedios. Whilst they were employed in this enterprise, General Sucre arrived at Lima with 3000 Colombian troops; but this force, with 2000 Peruvians, partly militia and partly the wreck of a former army, was found insufficient for the protection of the capital, against which Canterac advanced at the head of 9000 well-disciplined men. Lima was accordingly abandoned by the patriots, and immediately taken possession of by the royalists, who, however, soon afterwards evacuated it, after having exacted heavy contributions from the remaining inhabitants, and destroyed the mint. Both Generals Santa Cruz and Sucre, who with a united army might have accomplished something of moment, proved unsuccessful; and the former allowed himself to be out-generalled by Canterac. The cause of independence in Peru seemed hanging by a thread, which it required little exertion to break, when the celebrated Bolivar made his appearance in Lima on the 1st of September 1823. He was received with the greatest enthusiasm, and was immediately invested with supreme authority, military and political. Great activity was now infused into the measures of government; and acting in the capacity of dictator, Bolivar dissolved Congress, and levied an army, with which he sallied from the capital on the second week of November. Riva Aguero refused to join him, and was imprisoned by his own troops, who immediately submitted to the dictator. But a fresh misfortune awaited the patriots in the mutiny of the soldiers at Callao. The consequence was, that this town, along with the city of Lima, once more fell into the hands of the royalists. The cause of independence in Peru now seemed desperate; but the conduct of Bolivar at this critical moment is deserving of the highest praise. By his firmness, activity, and seasonable severities, he checked further defections, and obtained the respect and entire confidence of every true patriot.

In the month of July 1824 the liberating army commenced its march towards Pasco in three divisions, two of which were Colombians, headed by Generals Lara and Cordova; and one was Peruvian, under Lamar. General Sucre was chief of the staff of the whole army. In his preparatory measures for facilitating the passage of the troops on a march of 200 leagues, through the most mountainous region in the world, this officer displayed great skill; and the army reached the old Pasco district in safety, and unmolested by the royalists. Various manœuvres now took place; and in an action of cavalry at Junin the patriots inflicted a severe blow on their adversaries. A series of marches and countermarches occupied the months of August, September, October, and November; and on the 6th of December the patriots reached the village of Quinua; whilst the royalists, by entering Guamangilla, cut off their retreat, and placed them in an extremely critical situation. On the 8th, the viceroy Lascerna moved from this position, and occupied with his whole force the heights of Condorkanki, within gun-shot of the encampment of the patriots. Between the opposing armies lay the plain of Ayacucho. It is in shape nearly square, about a league in circumference, and flanked right and left by deep and rugged ravines. The eastern boundary is formed by the abrupt and savage ridge of Condorkanki, whilst the western extremity is the Indian village Quinua, a little distance in front of which lay the patriot army, not 6000 strong, that of the royalists being fully one-third more numerous. Next morning, the 9th of December 1824, the conflict took place, and continued for about an hour, when the royalists were defeated with great loss. Indeed their army may be said to have been almost annihilated; for 3200 rank and file, amongst whom was the viceroy, were made prisoners of war, the remainder dispersing in a state of total disorganization in all directions. The battle of Ayacucho is pronounced by Mr Miller "the most brilliant ever fought in South America;" and it may be considered as the last regular engagement, although not the last struggle, in which Spain was engaged for the recovery of her revolted colonies. Rodil still held out at Callao for the mother country with the most desperate tenacity. For thirteen months he sustained, unaided, bombardments both by sea and land, rendered still more terrible by the accumulated miseries of pestilence and famine. At length he capitulated upon honourable terms on the 19th of January 1826; and thus the last link of the chain which had bound America to the Spanish crown was finally broken.

Bolivar continued dictator till the month of July 1825, when he resigned, and placed at the head of affairs a council of government composed of his own ministers. Towards the end of 1826 he promulgated a new constitution, according to which the executive was to be vested in an irresponsible president elected for life. This new constitution excited great discontent among the people; but it was accepted by the electoral colleges, and Bolivar was named president. The people were further incensed by the presence of the Colombian troops; and soon after, Bolivar being called away to quell an insurrection in Colombia, an open revolt broke out in Peru. The Colombian troops were expelled from the country, a Congress was assembled at Lima, and the Bolivian constitution abolished. On the 18th of June 1827 a new constitution was promulgated, and General Lamar named president. An increased dissatisfaction between Colombia and Peru at length led to a declaration of war between the two states; and Lamar entered the Colombian territory at the head of a considerable army. A battle took place on Tarqui, near Jiron in Quito, on the 27th of February 1829, in which the Peruvians were defeated, and the next day preliminaries of peace were agreed to. The imbecility manifested by Lamar on this occasion gave rise to a conspiracy against him, and he was deposed in the month of June by General Gamarra, who convoked a Congress, and caused himself to be nominated president. He retained office for the four years designated by the constitution; and at the end of this term a convention was convoked to reform the constitution. The reformed constitution was promulgated in the month of August 1834, and General Orbegoso was named president. In January 1835 General Salaverry, who commanded the garrison at Callao, instigated the troops to declare against the government at Lima, and took possession of that city, declaring himself supreme chief of the republic. The president Orbegoso, who was at this time in the southern provinces, finding himself unable to cope with Salaverry, applied for aid to Santa Cruz, president of the Bolivian republic. That general accordingly entered Peru with an army, and joining forces with Orbegoso, the combined army came up with the enemy at Cuzco. Salaverry had committed the command of his army to Gamarra, remaining himself at Lima. The battle took place at Yauacocha on the 13th of August, when Gamarra was totally defeated, the greater part of his troops having gone over in a body to the enemy. Salaverry lost no time in preparing to meet the enemy; and having collected a body of about 2500 men, posted him-

Peru.

self on the heights of Challapampo, to the north of Arequipa. Towards the end of January 1836, the united forces of Orbegoso and Santa Cruz, amounting to double the number of those of Salaverry, advanced to attack him; but he had fortified himself in such a manner that they were obliged to have recourse to stratagem. This was the adoption of a retrograde movement, which led the enemy to believe that they were in full retreat, and drew them from their strong position. Santa Cruz, seizing the favourable moment, fell upon them with great vigour. The contest was obstinate; but the issue was not long doubtful. Salaverry was completely defeated, and himself and most of his army taken prisoners. Salaverry, with seven other officers, were tried by a court-martial, condemned to death, and shot on the 18th of February. Lima, Callao, and the rest of Peru immediately submitted to the conquerors. Santa Cruz having succeeded in establishing tranquillity, now assumed the supreme power; and, dividing the country into North and South Peru, he conjoined it with Bolivia, nominating himself supreme protector of the three states. This arrangement met with a powerful opposition both in Peru and Bolivia, and also brought him into collision with the republic of Chile. At length, in January 1839, a bloody battle was fought at Yungay, in which Santa Cruz was defeated, and driven out of the country. The confederation was thus brought to a close, and the two countries, Peru and Bolivia, returned to their former limits and forms of government. In Peru a Congress was convoked, which, in November 1839, gave out a new constitution, and nominated General Gamarra, who had commanded the Chile-Peruvian troops, president of the republic. General Gamarra died in November 1841, and Señor Menendez, president of the council of state, entered into power, but was deposed in the month of August 1842 by General Torico. A civil war followed, and the government passed successively into the hands of General Vidal, Señor Figuerola, and General Vivanco. In 1844 the civil war was brought to an end by General Castilla, and Menendez replaced in power. A Congress was called in accordance with the provisions of the constitution, and General Don Ramon Castilla was elected president, and entered upon office on the 1st of April 1845. Castilla completed his six constitutional years of office, and under his rule the country enjoyed great peace and prosperity. His successor, General Echenique, assumed the supreme power on 1st April 1851, but the people soon became dissatisfied with him. His government was accused of committing the grossest frauds against the national credit by issuing *vales de consolidacion* on fictitious grounds; and hence the financial reputation of Peru fell into the lowest state of discredit. At length the people rose against the government, and, headed by Castilla, gained a decisive victory at the Palma, close to Lima, in the early part of 1855, and Echenique was driven from power. After the expulsion of Echenique, Vivanco stirred up an insurrection against Castilla, and having gained over the commanders of three of the government steamers, he was able to convey his troops rapidly from place to place, and thus maintained the struggle for some time. At Callao he suffered a severe repulse, and afterwards he congregated his forces in the town of Arequipa, a place which had always remained attached to him. His steamers prevented all approach by sea; and at one time they held possession of the Chincha Islands, with their guano treasures. Fortunately the war was at length brought to a close in March last (1858), by the taking, by assault, of Arequipa, after a most obstinate and heroic defence by Vivanco and his adherents, the number of killed and wounded amounting to about 3000. The confidence in Castilla's government is evinced in the fact; that the *vales de consolidacion* have risen in Peru from 43 to 80 per cent. Though slavery had been abolished by the charter of independence, yet it still continued to be carried on till prohibited by the present governor in 1855. He has also freed the Indians from the unjust capital tax to which they had been subject since the time of the Spaniards. Among the other changes that have been introduced is a law by which illegitimate children are entitled to one-fifth part of the moveable property of their parent. The punishment of death for political offences has also been abolished.

Name.

The name *Peru* was not known to the early inhabitants, but was given to the country by the Spaniards; and is said to be a corruption of the word *Pelu*, the Indian name for "river," and mistaken by the Spaniards for the name of the country. The name given to it by the natives was *Tavantinsuyu*, or "four quarters of the world."

Physical character.

The most distinguishing natural feature of Peru, and that from which the country derives its peculiar aspect and character, is the vast chain of the Andes, which traverses it in a direction from S.S.E. to N.N.W. The country is thus naturally divided into three distinct regions, differing widely from each other in their physical characteristics, and familiarly known as *La Costa*, or the region between the sea and the Andes; *La Sierra*, or the mountain region; and *La Montaña*, or the wooded region to the E. of the Andes, forming part of the basin of the Amazon.

Coast.

La Costa, or the coast region, extends the entire length of the country, but its average breadth is not more than 30 miles. In some places it does not exceed 10, but in others it is more than 58 miles in width. With all its extent of coast, Peru has few good harbours, probably not more than a dozen in all. The best are those of Payta, Salinas, Callao, Pisco, Islay, Arica, and Iquique. The water on the coast being almost uniformly deep, vessels are obliged to approach within a quarter of a mile of the shore before they can anchor; and as the great swell of the Pacific occasions a heavy and dangerous surf, landing with boats is both difficult and hazardous. The operation, however, is effected with ease and safety by means of *balsas* or rafts, constructed usually of cane, and supported by means of inflated seal-skins. The coast region is almost one continuous sandy waste, where no rain falls, and where neither plant nor animal can obtain subsistence. Vegetation is only to be met with along the banks of the streams that come down from the high lands. Many of these are dry for the greater part of the year, and only a few of them are perennial. Some of the larger streams reach the sea, but the smaller ones are absorbed by the encompassing desert, or exhausted in irrigating the cultivated patches. The insulated river valleys are thus the only habitable parts of the coast, and they are from 20 to 90 miles apart. The rest of the region is covered with a fine light-yellow drift-sand. It presents, however, great inequalities of surface, being frequently intersected by sand-hillocks called *medanos*, which are sometimes of considerable size. Some of these are permanent, but others are driven about with great velocity by the wind, which, when violent, frequently raises columns of sand to the height of 80 or 100 feet. The rainless region extends to the height of about 7000 feet above the level of the sea; but to the height of about 2000 feet above the sea the coast region is periodically refreshed by sea vapours or drizzle, called *garua*. These vapours prevail from May to November, and are most dense and abundant towards the end of June, when the *lomas* or hillocks bordering the sand-flats become covered with a luxuriant vegetation. At Lima this coast vegetation is most abundant in the months of July, August, and September. The heat of this region is not so excessive as might be supposed; and during summer the thermometer rarely rises above 85°:—the mean annual temperature is 72°, the maximum 82°, and the minimum 55°. In this district are produced most of the plants of tropical countries. The plantain, banana, pine-apple, sugar-cane, vine, cocoa, olive, coffee, and cotton, as well as

Peru.

the most delicious fruits, some peculiar to the country, arrive at great perfection. Maize, rice, wheat, barley, and potatoes are also cultivated. (See two papers, by Dr Archibald Smith, on the Climate of Peru, in the *Edin. New Phil. Jour.* for October 1857 and January 1858.)

Sierra.

The district called *Sierra*, or highlands of Peru, commences immediately above the rainless district, at 7000 feet above the level of the sea, and extends to the eastern chain of the Andes. The Andes here consist of two main chains or cordilleras, running nearly parallel to each other, and connected in various parts by cross ridges; but they do not in general rise to such a height as in Bolivia. The eastern cordillera from Bolivia preserves its grand character northward to 13. S. Lat., being composed of a series of snowy peaks, which terminate in the Nevada de Sacantahi; but N. of this no snow-capped mountains occur. In the western chain, near 15., a considerable portion of the range is covered with snow; S.E. of Lima the Toldo de Nieve rises above the snow-line; and between 11. and 11. 30. is the elevated summit of La Vinda, nearly 16,000 feet in height, and the nevadas of Pelagotas, Mayapota, and Huayhillas. Between the last mentioned and Chimborazo in Ecuador none of the summits of this chain attain the snow-line. The chains of the E. and W. cordilleras are usually about 100 miles apart. South of 11. S. Lat., the country between the two chains consists properly of two inclined planes sloping down from the Andes of Vilcanota and the table-land of Pasco, and separated from each other by the water-line of the Mataro, a feeder of the Apurimac, near 12. S. The southern plane lies at a great elevation, the town of Cuzco being 11,380 feet above the level of the sea; but even here wheat and Indian corn are raised, and farther N., where the country is considerably lower, the sugar-cane is cultivated. The surface is by no means level, being traversed by various ridges of hills, which rise several hundred feet above their bases. The northern plane has a very similar surface; and contiguous to the western cordillera it forms an undulating valley 40 miles wide, which is drained by the Jauja, and which, on account of its fertility, is one of the best peopled districts of Peru. In the lower part of this valley the sugar-cane succeeds well; while the higher produces cereals and fruits in abundance. To the N. is the table-land of Pasco, which lies between 11. and 10. 30. S., and, with the exception of a few miners' huts in the regions of permanent snow, is the highest inhabited part of the Andes. Were it not for the rich mines which it possesses, it would have remained a sheep-walk. Its surface presents several low but steep ranges of hills, with level grounds between them. These level tracts are from 13,000 to 14,000 feet above the sea, or about 1500 feet below the snow-line in this latitude. The climate is exceedingly cold all the year round, and unfavourable to any kind of cultivation. In the numerous and deep lakes which cover a considerable part of its surface, the rivers Marañon, Huallaga, and Ucayale take their rise. The northern portion of the Peruvian Andes consists of three cordilleras, of which the western contains the nevadas already mentioned. The central chain is connected with the table-land of Pasco, and runs parallel with the western chain to about 7°, their summits being about 50 miles apart; but northward of this parallel the chain runs N.E. to its termination on the banks of the Amazon. In the northern portion of this central chain a few summits occur which rise above the snow-line. The eastern cordillera is connected with the mountain system of the eastern border of the table-land of Pasco, and runs in a direction parallel with the central chain, terminating near 6° S., opposite an offset of the central range, which here comes close up to the Huallaga. The highest summits of this range are towards the S., but probably none of them much exceed 15,000 feet in height. Toward the N. they sink down to mere hills. Of the two valleys inclosed by these three ranges, the western, or that of the Marañon, is very narrow in its southern parts, and here the river is one continuous series of rapids and falls until it reaches 8°, where it enters a wider valley, which spreads out to 20 miles in width. This wider valley gradually subsides from 3000 to 2000 feet above the level of the sea. Its climate is consequently very hot, and its fertile soil is capable of producing all the intertropical plants and fruits. The eastern valley is drained by the Huallaga. It slopes very rapidly, from 5000 in 10° to 2000 in 9°, and in its fertility, climate, and produce resembles the valley of the Marañon. Dr Smith, in speaking of the climates of the Sierra, says,—"On ascending above the rain-line, a sparse vegetation at first appears, which gradually improves at every step, until the valleys of the Sierra open out into wide pasture-lands up to the snow-line, with many villages and farms all over the ridges and hollows of the mountains. When the western cordillera is crossed, the descent leads into a wide and open district of treeless undulating surface covered with flocks and herds of sheep, llamas, vecuñas, horses, mules, and horned cattle, &c. But from these lofty and inclement grounds valleys of different depth and temperature dip off in all directions, making the Sierra as a whole a region of the most varied climate and production. As a central point of Andine climate, we may take Cerro Pasco as an example. * * * * The wet season is from November to May (just the contrary to what it is on the coast); but December, January, February, and March are the more disagreeable months, the streets being then all wet and slushy. The weather varies extremely, not merely in the course of the same day, but within a very few hours, during which there may be rapid variations of snow, rain, hail, and sleet, gleams of sunshine, high and fluctuating gusts of wind, sudden obscuration from dense clouds drifting in the atmospheric currents, with flashes of lightning, and peals of thunder rolling among the mountain-peaks. For the other six months of the dry season, showers of hail, snow, or rain are only occasional and rare, the prevailing weather being sunny and cheerful by day, and dry and frosty by night. The thermometer of Fahrenheit I found to be about 42° by day, and 36° by night, in the wet season; but in the dry season the night indications fell to 30°, or under." (*Edin. New. Phil. Jour.*, vol. vii., pp. 50–1.)

Presenting as it does almost every variety of climate, the vegetation of this region is extremely varied in its character, from the gigantic growth of the tropics to the dwarf plants of Lapland. In this mountainous district are situated the famous gold and silver mines of Peru. It likewise contains the sources of those vast rivers which traverse the continent of South America. Here the Marañon commences its course, and here rise its magnificent tributaries, the Ucayale, Huallaga, and others, which themselves are swelled by an innumerable multitude of streams descending from the eastern ridges of the Andes,—all being finally absorbed in the mighty Amazon.

Montaña.

But by far the most beautiful and valuable part of the Peruvian territory is the *Montaña*, or wooded region, which lies to the E. of the Andes., commencing on the eastern declivity of the second chain, and stretching to the confines of Brazil and Bolivia. After crossing the Andes, and descending a few hundred feet lower in the direction of the E., the traveller beholds a country totally different from that which he has left—a country richly covered with a luxuriant vegetation. So far as we are acquainted with this region, and as yet it is only imperfectly known, it seems to rival in fertility, and in the luxuriance and variety of its vegetation, even the finest parts of Brazil. "Here," says Dr Poeppig, "are plains traversed by lower hills covered with an ocean of foliage, vieing in beauty with the climate of Chile, and far surpassing it in the abundance and

Peru.

luxuriance of its productions." Dr Lorente, as cited by Dr Smith in speaking of the district of Chanchamayo, says:—"Here everything is on Nature's great scale. The whole country is one continuous forest, which, beginning at different heights, presents an undulating aspect. One moves on his way with trees before, above, and beneath him, in a deep abyss like the ocean. And in these woods, as on the immensity of the waters, the mind is bewildered; whatever way it directs the eye, there it meets the majesty of the Infinite. The marvels of nature are in these regions so common, that one becomes accustomed to behold without emotion trees whose tops exceed the height of 100 varas (290 English feet), with a proportionate thickness, beyond the belief of such as never saw them; and, supporting on their trunks a hundred different plants, they individually present rather the appearance of a small plantation than one great tree. It is only after you leave the woods, and ordinary objects of comparison present themselves to the mind, that you can realize in thought the colossal stature of these samples of Montaña vegetation." The entire region is watered by the Huallaga, Ucayale, and Marañon, with numerous subsidiary streams. The vast plains in which the declivities of the Andes terminate are called sometimes Pampas del Sacramento, or, more usually, *Collona*, or the "Land of the Missions." This name they owe to the Jesuits, whose zeal for the conversion of the natives induced them to penetrate these trackless solitudes. They planted a number of settlements, and by collecting in villages the rude inhabitants, attempted to civilize them not only by instilling into their minds the doctrines of religion, but by teaching them such arts as their uncultivated natural talents enabled them to acquire. Some of these missions still exist. Numerous tribes of wild Indians are scattered over the country, differing from each other in character and language. Some of them are mild and docile, while others are warlike and savage, and continually in a state of hostility to each other. The heat here is not so oppressive as might be expected, being allayed by refreshing breezes that generally prevail. At Sarayacu the maximum temperature is about 85°, the minimum 74°. The rainy season prevails from November to May, during which it often rains for a week without intermission. The dry season is very agreeable, and though, where cleared of wood, the surface becomes parched, the moisture is always preserved a little below; so that there is no need of irrigation. The vegetable productions of the Montaña are numerous. Besides valuable woods, as cedar, ebony, mahogany, walnut, &c., there are pine-apples, almonds, lemons, oranges, citrons, and other fruits; and cacao, cinnamon, guaiacum, cinchona, sarsaparilla, vanilla, black wax, storax, dragon's blood, oil of Maria, gum-caraña, balsam of copaiba, copal, and many other gums, balsams, resins, and oils. Maize is everywhere cultivated, and rice is grown on the marshy banks of the rivers. Tobacco, cotton, indigo, and the sugar-cane are not among the least important of its products.

Rivers.

The rivers of Peru that fall into the Pacific are all short in their courses, shallow, and generally rapid. They are consequently useless for navigation, and serve only to irrigate the adjacent lands. The great rivers of Peru are the Marañon, Huallaga, and Ucayale, which drain the whole country E. of the W. cordillera, and constitute the principal branches of the River Amazon. They are for the most part navigable, and will doubtless at some future period serve, by means of steam navigation, to convey the wealth of this vast region to the ports on the Atlantic. Mr Markham, who in 1853 explored a portion of the Purus, an affluent of the Amazon which separates Peru from Bolivia, says,—"If once the Madre de Dios or Purus was thoroughly explored, the effects it would have on the industry and future prospects of Peru are incalculable. The people of the interior of that beautiful country, the ancient empire of the Incas, would at length succeed in turning the granite barrier of the Andes; a port might be established near Paucar-tambo, and another at the mouth of the Purus; an inland navigation would waft the varied productions of the interior of Peru—its bark, sarsaparilla, copaiba, and india-rubber; its sugar, cocoa, cotton, and tobacco; its alpaca wool, silver, and precious stones,—by a direct and easy route to the Old World; and the dangerous journeys across the cordilleras, and long and tedious voyages round Cape Horn, would be avoided." (*Geog. Soc. Jour*, 1855.)

Lakes.

The lakes of Peru, with the exception of Titicaca, are of small size. Lauricocha is interesting as the source of the Marañon; the Chinchacocha gives rise to the river Jauja; and the small lake of Urcos, to the south of Cuzco, is celebrated from the tradition that a chain of gold made to celebrate the birth of Huasca Inca was thrown into it. Titicaca is about 100 geographical miles in length from N.W. to S.E., and about 40 in greatest width. It is situated on a table-land surrounded by mountains, and is about 13,000 feet above the level of the sea. It contains several islands, the largest of which is about 20 miles in circumference.

Geology.

The geological character of this country has as yet been but very imperfectly investigated. Red sandstone is frequent on the coast, and also in the interior. Granite and porphyry occur on the coast; but the prevailing rocks on the sierras are trachite, augite, and diorite; though granite and porphyry are also common. In a journey from Lima to the summit of the western cordillera, along the course of the Rimac, Dr Smith noted in succession the following rocks:—Coarse-grained granite, syenitic granite, syenite, felspar porphyry, trachite porphyry, and porphyry. At this stage of the series a band of syenitic greenstone or porphyry, with actinolite, crops out across the road above Matucana (at the elevation of about 8000 feet). From this point to San Mateo, through a deep and narrow gorge of about 4 leagues in extent, the rocks, in ascending succession, are, prophyritic greenstone, trap, porphyry, and quartz; on opposite sides of the ravine, trap and limestone. About San Mateo (estimated at nearly 11,000 feet above the sea) he found greenstone; and in the steep ascent above this village, schist, porphyritic greenstone, and porphyry. From Chicla, a few leagues above San Mateo, to the foot of the cordillera, the prevailing rock is conglomerate, and the surrounding soil of a reddish colour. On approaching the cordillera pass by Tucto, the mule path leads over the iron-gray debris of the porphyritic Andine peaks which adjoin the silver mines of Alpamina, in a matrix of limestone above the line of perpetual snow. (See *Peru as it Is*, vol. i., ch. xi.) The sides of the valleys between Titicaca and Cuzco are formed chiefly of clay-slate. Round Arequipa, and thence to Titicaca, the soil is all volcanic; but there is no active crater in the district, though the cone of Arequipa still emits smoke. Earthquakes are frequent, and occasionally very destructive, on the coast.

Minerals.

Peru has long been famous for its wealth in the precious metals, especially gold and silver. The latter is the more common, and is widely distributed over the country. The principal mining regions are those of Hualgayoc, near Micuipampa; Gualanca in Huamalies; Pasco; Lucanas; and Huantajaya; but small mines of it are worked secretly all over the country. The treasures contained in the Cerro de Fernando, at Hualgayoc, were first discovered in 1771; and there are now about 1400 pits opened in the hill. Cerro de Pasco is hardly inferior in mineral wealth to Potosi; and the hill on which the town stands is completely undermined, most of the openings to which are within the houses of the miners in the town itself. The richest gold mines or diggings are about Huaylas and Tarma. Most of the rivers from the Andes bring down auriferous sand. Quicksilver is likewise found, but in such small quantities as not to

repay the labour of the miners. The only quicksilver vein of any magnitude is at Huancavelica. Both mountain chains are very rich in copper ore, but it is only worked on the western cordillera, as the distance of the other from the coast renders the transport too expensive. The lead and iron mines, though prolific, are not worked, the price of these metals being too small to repay the expense of working. Coal has been discovered in the Cerro de Pasco, and brown coal is found in the sandy deserts N. of Arica. In the province of Tarapaca is a forest of prostrate trees buried beneath the sand, which affords excellent fuel, and is much used in the preparation of nitre. It is neither charred nor petrified, and burns with a flame as bright as that of common wood. In the S., and chiefly in the maritime province of Tarapaca, are extensive deposits of salt, nitre, and nitrate of soda. The Pampa, or great plain of Tamarugal, which extends the whole length of the province, running N. into the province of Arica, and S. into the desert of Atacama, and about 30 miles wide, abounds with salt, nitrate of soda, and other saline bodies. The principal deposits of nitrate of soda are found on the western side of the Pampa, at some distance from the coast, in approaching which it seems as if it gradually transferred itself into salt. The beds are insulated deposits, varying much in size and shape—in thickness from 6 inches to as many feet, and in depth, beneath the surface crust of earth and clay, from one inch to many feet. Among the other salts found in the vicinity may be enumerated carbonate and sulphate of soda, biborates of lime and soda, magnesian alum, and chlorate of sodium. Traces of iodine exist in the nitrate, and in most of the waters in the plain traces of boracic acid have been discovered. The existence of nitrate of soda in Tarapaca has been known in Europe for about a century, but it is only recently that its value has been found out. In 1820 some of it was sent to England, but the duty being so high, it was thrown overboard. In 1830 a cargo was sent to the United States, but was found unsaleable; and a portion of it sent to Liverpool met with no better success. In 1831 another cargo was sent to England, and by this time it had become better known, and sold as high as 30s. to 40s. the cwt. From 1830 to 1850 the exports of this mineral from Iquique, the principal port of the province, amounted to 239,860 tons. Vast deposits of salt occur not only on the coast, but even on the Sierra. To the E. of the volcano of Isluga commences an extensive salt plain, said to extend to Challaputo and the insulated Cordillera del Frayle, 40 leagues distant, and near to Potosi, varying in breadth from 3 to 8 leagues, the salt being from 5 to 10 inches thick. The elevation of this plain is at least 14,000 feet.

Vegetable productions, &c.

The more important of the vegetable productions have already been noticed. Among those which at present constitute articles of use and commerce are,—coffee, sugar, wheat, barley, maize, rice, potatoes, copaiba, sarsaparilla, Peruvian bark (*cinchona*), cotton, cocoa, indigo, tobacco, caoutchouc. In describing the qualities of some of these, and the quantities in which they are produced, Thadeus Haenke observes:—"The cocoa of Apolobamba, of Moxos, of Yuracarees, and of all the woods which extend from thence to the shores of the Marañon, is infinitely superior to that of Guayaquil. The finest quality of cascarilla is only found on the eastern side of the Andes; of the indigo there is no end; I can say the same of the cotton and the rice. The precious balsam of copaiba, the sarsaparilla, the gum-elastic, and the most fragrant species of vanilla, are all produced in an extraordinary abundance in these regions. The mighty forests which line the shores of the rivers abound in the finest timber for all uses, especially for ship-building, and in trees distilling the most aromatic and medicinal gums. Among others, there is a species of cinnamon, called by the natives *canela de clavo*, which only differs in the greater thickness of the bark and its darker colour, according to its age, from that found in the East Indies, and which is as fragrant as the spice from which it takes its name (clove)." (*Geog. Soc. Jour.*, vol. v., 1835.) The grapes are so abundant in some parts that large quantities of wine might be made for exportation; but no more is produced than is needed, and a little is even imported. Strong liquors, such as brandy and rum, are distilled; and oil is made from the olive. The various kinds of capsicums are cultivated with more attention and skill than almost any other plants; and when dressed in various ways with garlic, form an important article of food to the greater portion of the inhabitants. Paraguay tea has now ceased to be a common beverage. A liquor in universal use is the *chicha*, which, from having been found in the tombs of the aborigines, is proved to have been used by them prior to the conquest. The chicha of the present day is of the consistence of milk, of a yellowish colour, and when poured from one vessel into another, froths like beer. Its taste is generally acid; but when very fresh, the acidity is scarcely perceptible. It is made by steeping Indian corn in water till it swells, after which it is dried and ground. The flour and bran are boiled in water, strained, and left to ferment for four-and-twenty hours, when it is fit for use. There is a fruit called *chouta*, from which the Indians prepare an intoxicating liquor; but the great nervous stimulant used by them is the *coca*, which is very extensively cultivated, and has become an indispensable necessary of life. The coca plant (*Erythroxylon coca*) is from 6 to 8 feet in length, and somewhat resembles a black thorn in its numerous small white blossoms and the lively bright green colour of its leaves. The latter are gathered and carefully dried, and then finely packed in woollen sacks and covered with sand. The coca-leaf is to the Indian of the interior a necessary of life. Each individual carries a leathern pouch containing a supply of coca-leaves, and a small flask gourd filled with pulverized unslaked lime. Three or four times a day, or oftener, he suspends his labour to *chaccha* or masticate his coca, to which a slight admixture of the powdered lime gives a relish, and is said to counteract the natural tendency of the coca to give rise to visceral obstructions. Deleterious and dire results are commonly attributed to the use of this narcotic; and Dr Poeppig, in his *Travels in Chili and Peru*, &c., draws a melancholy picture of the dreadful effects of this insinuating drug, and of the diseases to which it gives rise. It is asserted, however, by those best able to judge, that these effects are vastly overrated; and some even maintain that, when used in moderation, it may be even conducive to health. Among the latter is Dr J. Von Tschudi, who refers to the numerous instances of longevity among the Indians, who almost, from the age of boyhood, have been in the habit of masticating coca three times a day, and who nevertheless have enjoyed perfect health. (*Travels in Peru*, 1847.) Dr Archibald Smith, a physician of long experience in the country, says that, "Used in moderate quantity, the coca, when fresh and good, increases nervous energy, removes drowsiness, enlivens the spirits, and enables the Indian to bear cold, wet, great bodily exertion, and even want of food, to a surprising degree, with apparent ease and impunity. Taken to excess, it is said to occasion tremor in the limbs, and what is worse, a gloomy sort of mania. But such dire effects must be of rare occurrence; since, living for years on the borders of the Montaña, and in constant intercourse with persons accustomed to frequent the coca plantations, and with Indian yanacones or labourers, all of whom, whether old or young, masticated this favourite leaf, we never had an opportunity of witnessing a single instance in which the coca-chewer was affected with mania or tremor." (*Peru as it Is*, London, 1839.)

Among the wild animals of Peru are the puma, jaguar,

Peru.

Animals.

bear, deer, wild boar, fox, skunk, armadillo, sloth, and several species of monkey. Alligators are met with in the rivers, and seals are common on the coast. Tortoises frequent in great numbers the inlets of the coast. Several species of serpents are found, but they are rather rare. A viper of a very poisonous nature inhabits the sugar-cane fields, and its bite is almost instantaneously mortal. On the shores of Peru are myriads of sea-birds, to whom we are indebted for that valuable manure, guano. Of land birds, falcons, hawks, owls, pigeons, &c., abound. There are four varieties of condor, and the common carrion-vulture frequents the cities and towns. Most valuable among the animals indigenous to the country are the Peruvian sheep, of which there are four varieties—the llama, alpaca, guanaco, and vicuña. The first of these is the least valuable on account of its wool, and was chiefly employed by the ancient inhabitants as a beast of burden. Its wool is long and rough, and is used only in the manufacture of coarse cloths. Though the introduction of horses, asses, and mules into the country since the conquest has rendered the llama less necessary as a beast of burden, it is still much used for that purpose. They usually travel in large flocks at the rate of three or four leagues a day, and each carrying about a hundredweight. The alpaca or paco is smaller than the llama, and yields a very fine, long, soft wool, which is now largely imported into England and other countries. They are kept in large flocks on the heights. The guanaco is the largest of the four varieties, and very much resembles the llama in form. They usually roam in a wild state in groups of four or five on the upper declivities of the western cordillera. The wool is shorter and coarser than that of the llama. The vicuña is in size between the llama and the alpaca, and is a more beautiful animal than any of the other varieties. They inhabit the cold heights of the cordillera, and are always in herds of from six to fifteen females, and one male, who is the leader and protector of the rest. The vicuña is distinguished by the superior fineness of its short curly wool. After the conquest the Spaniards introduced their own breed of sheep into the country; and it is now very common. There are flocks of 80,000 or 100,000 sheep on the inter-cordillera plains of Bonbon and neighbourhood. Horses, asses, and black cattle were also introduced by the Spaniards; and in the valleys and on the coast they are well developed, but on the heights they are small and stunted in their growth.

Manufactures.

The manufactures of Peru are inconsiderable, the great body of the people being employed in agriculture and the mines. Labour of every kind is in the hands of the Indians; and though they manifest considerable ingenuity in some of the mechanical arts, from the want of sufficient instruction or of proper masters, their productions will not bear comparison with those of Europeans. They manufacture a variety of cotton and coarse woollen fabrics, which are consumed in the country. Straw hats of a variety of colours, petates or mats, and sigarreros, also form part of their manufactures. Goat skins are made into good cordovan; and cow-hides are made into saddle-bags, and almofrezes, or travelling-cases for bed and bedding. Tanning, dyeing, soap-making, distilling, and some other manufactures are carried on. Very fine gold and silver filigree work is also executed. Peru, however, looks to Europe for a great part of the necessaries as well as of the luxuries of life.

Trade.

The principal exports of Peru are the precious metals, guano, nitrate of soda, wool, cotton, hides, and Peruvian bark. Guano, which till recently had no place among its exports, is now the most important of its productions. It is found on some parts of the coast, but principally on certain small islands, especially those opposite to Pisco. On the islands of Chincha alone it was estimated that in 1854 there were 12,376,100 tons. In 1854 no less than 344,400 tons of guano were exported, of which more than one-half went to England, and the remainder to the United States, France, Spain, Germany, &c. The imports consist of woollen, cotton, and linen stuffs; machinery, cutlery, earthenware, &c. The trade of Peru with the various countries was as follows in 1853:—

Countries.	Imports.	Exports.
Britain	L.923,258	L.1,763,751
China	57,899	.
Chile	130,800	99,487
Spain	32,473	45,799
Ecuador	39,365	..
United States	117,205	979,676
France	376,756	288,321
Hamburg	97,265	42,963
Antilles	.	52,848
Other countries	42,555	103,216
Total	L.1,817,576	L.3,376,061

It will be seen from this table that Great Britain is the country that carries on the greatest trade with Peru. It imports almost double, and exports nearly three times as much, as any other country. The declared or computed value of British imports from Peru, and of exports thereto in 1856, was as follows:—

Imports.		*Exports.*	
Guano	L.2,053,386	Cotton goods	L.450,376
Alpaca and llama wool	386,798	Woollen	258,998
Sheep wool	111,304	Hardwares and cutlery	56,110
Nitre	220,762	Iron & steel, unwrought	37,273
Copper and copper ore	86,165	Linen goods	41,323
Tin and tin ore	58,399	Silk manufactures	20,692
Peruvian bark	59,099	Apparel	25,499
Cotton, raw	24,542	Earthenware	20,042
Chinchilla skins	5,174	Machinery	7,458
Untanned hides	1,495	Coals	11,778
Cochineal	3,968	Wine	6,879
Borax	2,877	Glass	7,396
Other articles	34,725	Other articles	128,340
Total	L.3,048,694	Total	L.128,340

The internal trade of Peru is not great, owing to the nature of the country and the want of good roads. Except on the table-lands, indeed, there are few roads of any sort. Mules are generally used for the conveyance of travellers and goods; though in the more elevated parts llamas are largely employed for the latter purpose. A railroad extends from the port of Arica to Tacna, and another from Callao to Lima.

The government of Peru is by its constitution pronounced to be a popular representative government; and in theory at least the sovereignty emanates from the people, who are supposed to delegate its exercise to the legislative, executive, and judicial powers of the republic, each of which is independent of the others. The chief executive power is vested in the president, who is elected for six years through the electoral colleges. He has four ministers for the despatch of public business,—one for foreign affairs, one for finance, one for justice and religion, and one for war and marine. The legislative power is vested in a Congress, composed of a Senate and Chamber of Deputies. The Chamber of Deputies consists of representatives chosen by the electoral colleges of the several provinces, in the proportion of 1 for every 20,000 inhabitants, or for any fractional number above 10,000. But any province having an entire population of less than 10,000 is nevertheless entitled to elect a deputy. The Senate is composed of two members for each of the departments. The electoral colleges of the provinces are composed of parochial electors, 1 for every 200 inhabitants in each parish. Each department is politically governed by a prefect, under immediate subordination to the president of the republic; each province by a sub-prefect, subordinate to the prefect; and each district by a governor, subordinate to the sub-pre-

fect. In the capital of each department there is a *junta* composed of two members from each province, elected in the same way as the members of the Chamber of Deputies. Justice is administered by the Supreme Court at Lima, and the superior courts of Lima, Cuzco, Arequipa, Truxillo, Ayacucho, and Puno. In the provinces are courts of primary instance; and in the districts, justices' courts. Besides these, there are special commercial, mining, military, and other courts. The judges are appointed by the president, but are not removeable without sufficient cause. Capital punishment for political offences has been abolished. The land forces of the government consist of about 10,000 men of all arms; and the naval forces, of a frigate, two corvettes, and two galliots. The total national debt amounted, in 1853, to L.9,954,000 sterling. The budget for 1855 estimates the revenue at L.1,874,000 (of which L.1,243,750 is derived from the sales of guano), and the expenditure at L.2,177,643. According to the constitution, the religion of the republic is Roman Catholic and apostolic, and the exercise of none other is permitted. Practically, however, Protestant worship is allowed in private, and an English clergyman regularly officiates at the British consulate. Ecclesiastically, the country is divided into an archdiocese, and the bishoprics of Cuzco, Arequipa, Truxillo, Guamanga, and Chachapoyas. There are 1800 priests or clergymen, 720 friars, and 1200 nuns. The tithes produce annually L.50,000, and the first-fruits L.120,000. There are 26 hospitals in Peru—21 for males, with 1226 beds; and 5 for females, with 497 beds; average annual cost, about L.50,000. Except in larger towns, education is at a very low ebb. In the remote interior, men able to read and write are not always to be found to fill public offices. In the capitals of the departments there are usually high schools or colleges; and there are good private schools in all the more populous districts. The university of St Mark at Lima is the most ancient of the American universities, having been established in 1570, and was long famous as a seat of learning, but it is now superseded in Lima by the college of S. Carlos. The university of S. Fernando in Lima is a thriving medical school. According to the last census, there were in Peru 810 elementary schools, where 26,000 boys and 3600 girls were taught reading, writing, and the catechism; and 42 lycea and high schools, having 320 masters and 4500 scholars. The Latin classes contained 1173 boys, the mathematical 720, the French 550, philosophy 328, Spanish grammar 270, religion 235, English 90, law 50, theology 250, medicine and surgery 50. The annual expense of the government schools and colleges may be estimated at about L.25,000, raised principally from excises, rents of land belonging to them, bull-fights, and sums paid by the pupils.

Peru is divided into 11 departments and 2 littoral provinces, having the organization of departments. The departments are subdivided into 61 provinces, the provinces into 625 districts, and the districts into parishes. The departments, with their population in 1852, are as follows:—

Departments.	Pop.	Capitals.	Pop.
Amazonas	43,074	Chachapoyas	4,500
Ancach	219,145	Huaras	5,200
Arequipa	119 336	Arequipa	36,800
Ayacucho	132,921	Ayacucho	16,700
Cuzco	349,718	Cuzco	44,600
Huancavelica	79,117	Huancavelica	5,200
Junin	222,949	Cerro de Pasco	12,800
Libertad	266,553	Truxillo	6,300
Lima	250,801	Lima	100,000
Moquegua	61,432	Tacna	9,700
Puno	285,662	Puno	8,300
Callao, prov. litt.	8,453	Callao	6,000
Piura	76,332	Piura	11,600
Total	2,115,493		

The inhabitants of Peru consist of three distinct races—Spaniards, Indians, and Negroes. The secondary classes arising from these three are,—the Mulatto, from the Spaniard and Negro; the Mestizo, from the Spaniard and Indian; and the Chino, from the Indian and Negro. The minor subdivisions are very numerous. The Indians, or native Peruvians, are still the most numerous class throughout the country, and constitute fully two-thirds of the entire population. They are naturally timid, reserved, and of a melancholy temperament, arising doubtless in great measure from the cruel oppressions to which they have been for ages subjected. They yet cherish a deep and mournful impression of the days of the Incas; and in the more remote districts of the country, the death of the last of the race is annually celebrated by a sort of rude tragedy, accompanied by plaintive strains of music. They are sunk in gross ignorance; but not a few of them have risen to eminence, and have shown themselves to be possessed of talents and abilities of no mean order. Many of the tribes are industrious cultivators of the soil; and others display great ingenuity in the manufacture of beautiful fabrics. They have also shown themselves to be possessed of bravery by their achievements during the war of independence; and so late as March 1858, they fought like old Spartans under Vivanco at Arequipa. Of the regiment Ayacucho, 600 strong, 540 fell at the barricades before they were overpowered by the army of Castilla. The mixed races are more numerous than the pure Spaniards. According to Mr Stevenson, the Mestizo is strong and swarthy, with very little beard, laborious, and well disposed; the Mulatto is less robust, but acute, talkative, imaginative, and fond of dress and parade; the Chinos have the character of being the worst of the mixed races,—they are a quick, pugnacious, and daring set of fellows. (D. K.)

PERUGIA, a province of the Papal States, bounded on the N. by the province of Pesaro-e-Urbino, E. by those of Macerata and Spoleto, S. by those of Spoleto and Viterbo, and W. by Tuscany. Its length from N. to S. is about 60 miles; extreme breadth, 45; area, 1547 square miles. It lies entirely in the basin of the Tiber, and contains the lake of Perugia, anciently called *Trasimenus*, near the frontiers of Tuscany. This sheet of water, which is about 30 miles in circumference, 8 broad at the widest part, and about 30 feet deep, contains several islands, and is inclosed on three sides by mountains, which on the fourth, towards the west, open out into the plain of Cortona. It is fed by springs rising from its bottom, and having no natural outlet, it frequently overflowed the surrounding country, until in the fifteenth century a tunnel and canal were constructed, which carry off the water from the south-east corner to the Tiber. The Apennines extend along the eastern boundary of the province, and cover it with their ramifications; but to the south of the capital there are some extensive plains. The soil is rich and fertile, and the climate mild and healthy. Corn, wine, oil, silk, and grass are raised; and large herds of excellent horned cattle are fed on the pastures of the province, as well as sheep, pigs, and poultry. Manufactures of cotton, woollen, and silk goods are carried on, and these articles are the objects of a considerable trade. Pop. (1853) 234,533.

PERUGIA (anc. *Perusia*), the capital of the above province, stands on the sides and top of a hill, between 700 and 800 feet high, overlooking the Tiber, 82 miles N. of Rome. It is surrounded by high but not very strong walls in the form of a polygon, about 6 miles in circumference, and is defended by a castle, erected by Pope Paul III. in 1543. Though irregularly laid out, the streets are broad, and are lined with many handsome buildings. Of the nu-

merous churches in the town, the principal is the cathedral, a Gothic edifice of the fifteenth century, containing numerous fine paintings by Barrocci, Guido, and Perugino, as well as four of Raphael's, and having an extensive library of biblical works and MSS. The church of S. Francisco, a fine edifice, formerly contained Raphael's picture of the "Descent from the Cross," now in the Borghese gallery; and that of S. Dominico has a fine painted window, and the beautifully carved tomb of Pope Benedict XI. The town-house, a large Gothic edifice, is the residence of the municipal authorities, and contains the archives of the town. The old Exchange, now no longer used for that purpose, is remarkable for the frescoes, by Perugino, with which its walls are covered. Many of the convents in the town are large and splendid, and contain fine paintings; that of San Pietro is the largest Benedictine convent in the Papal States. The university of Perugia, founded in 1307, is one of the oldest in Europe; it is attended by upwards of 200 students, and has a library of 30,000 volumes, a botanic garden, and collections of minerals and of antiquities. There is here an academy of the fine arts, with a collection of paintings by natives of the town and neighbourhood, and several private picture-galleries. Perugia has a school of music and a literary club; and also two theatres, assembly-rooms, and a bull-ring. A lunatic asylum is the chief benevolent establishment. The manufactures of the place consist of carpets, velvet, silk, woollen stuffs, soap, candles, brandy, and other articles. An active trade is carried on in corn, wine, oil, cattle, and wood. Perugia is the seat of a bishop and of a Papal delegate; a court of justice and a board of police are also held here. Many interesting remains of antiquity still exist in the modern town. It is doubtful whether the walls, which consist of long rectangular blocks regularly arranged, are of Etruscan or of Roman origin; to the latter must be ascribed the gates, two of which remain in their ancient condition,—the Arco d'Augusto, probably built by Augustus, and the Porta Marzia. Undoubted Etruscan remains are to be found in the sepulchres outside the walls, from one of which was obtained the only considerable fragment we have of the Etruscan language—an inscription forty-six lines in length, now preserved in the museum at Perugia. The ancient city was of much less extent than the modern, occupying only the summit of the hill. It seems to have been originally an Umbrian city; but it passed into the hands of the Etruscans, and became one of the chief members of that confederacy. It is mentioned frequently in early Roman history, though not before 310 B.C. It was then an independent city, frequently at war with Rome. After 294, it is not again mentioned as independent; but the precise time and circumstances of its conquest by Rome are not known. During the second Punic war it was one of the allies of Rome, and remained faithful to that power, supplying corn and timber for the fleet of Scipio. Perusia does not again occur in history until the civil wars of the second triumvirate. In 41 B.C. L. Antonius, attacked on all sides by Octavius, Agrippa, and Salvidienus, established himself in Perusia, hoping to hold out till he should be reinforced by Ventidius and Asinius Pollio. Disappointed in these hopes, and blockaded by Octavius, after an ineffectual attempt to break through the enemy's lines, he was forced to surrender. His life was spared; but the city was given up to plunder, and accidentally destroyed by fire. Rebuilt by Augustus, the town acquired the name of *Augusta Perusia*, and soon became a flourishing municipal town. It is not again mentioned till after the fall of the Western Empire; but in the wars which then took place it played a conspicuous part. After falling into the hands of the Goths, it was recovered in 537 A.D. by Belisarius; but on his departure it was taken by Totila. After this period it was an independent municipality, sometimes ruled by tyrants, sometimes divided by factions; till in 1512 it was united to the Papal States by Julius II. Pop. (1848) 19,400.

PERUGINO, Pietro, an eminent Italian painter, whose family name was *Vanucci*, was born at Citta della Pieve in 1446. His study of art was prosecuted amid the embarrassments of poverty. He acquired his first lessons while drudging as a shop-boy in the employment of a painter in Perugia. Then repairing to Florence, he commenced a regular course of study, with no means of support but the small pittance which his inexperienced pencil could earn. Yet in these unpropitious circumstances, Perugino soon attained great eminence. His pictures became notable for their graceful and elegant drawing, and their chaste and harmonious colouring, and began to be exported to various parts of Europe. At the same time, he was extensively and closely employed in the decoration of religious edifices in several different cities. He painted pictures for the churches and convents of Florence, Siena, Vallombrosa, Naples, Rome, and Perugia. So pressing, indeed, were his engagements, that he was often hurried into repeating the same figures, attitudes, and landscapes, over and over again. No less celebrated was Perugino as a teacher of art. The eminent painters Pinturicchio of Perugia, Rocco Zoppo of Florence, Giovanni Spagnuolo, and Andrea Luigi of Assisi, studied under him, and closely imitated his manner. The great Raphael, too, was his pupil, and for some time painted after his style. Perugino died at his native place in 1524.

Some of the extant works of Perugino are preserved in Florence. A celebrated fresco, representing the Crucifixion in the centre, with the Mater Dolorosa and San Bernardo on either side, is in the church of Santa Maria Maddalena de' Pazzi; and pictures of "Our Lord in the Garden of Olives," "The Assumption of the Virgin," "A Dead Christ," and "Two Monks of the Order of Vallombrosa," are in the Academy of the Fine Arts. (See Vasari's *Lives of Painters*, &c., and Lanzi's *History of Painting*.)

PERUVIAN BARK. See Bark.

PERUWELZ, a town of Belgium, province of Hainault, on an affluent of the Schelde, 12 miles E. by S. of Tournay, and 16 W. by N. of Mons. It is for the most part well built, and has a public square, a church, and several schools. The inhabitants are chiefly employed in weaving, bleaching, dyeing, tanning, and brewing. Pop. 7612.

PERUZZI, Baldassare, an eminent Italian architect, was the son of Sienese parents, but was born at Volaterra in 1481. The early part of his life was devoted to painting. He studied that branch of art at Siena, and then repairing to Rome, fairly commenced his professional career. The able and elegant composition of his pictures soon introduced him to notice. He was employed to paint some frescoes in the church of Sant' Onofrio, in the church of San Roccoa-Ripa, and in the fortress of Ostia. But by this time Peruzzi was turning his attention to a species of art better fitted to develope his talents. Having added to his skill in painting a knowledge of architecture, he now began to undertake both the designing and embellishment of edifices. He erected and ornamented many façades and other buildings. The most successful of these was the Farnese Palace, which was so exquisitely constructed that, according to Vasari, it "ought rather to be described as a thing born than as one merely built;" and so successfully adorned that Titian, on visiting it, thought at first that the painted objects were real. In spite of this professional success, the close of Peruzzi's life was shadowed by misfortune. The Spaniards, while sacking Rome in 1527, stript him of all his effects. His subsequent works, and among others his design for the unrivalled Palazzo Massimi, contributed very little to his pecuniary advantage. He died in 1536, leaving his family in indigent circur

stances, and was buried in the Pantheon, near Raphael. One of Peruzzi's paintings, "The Adoration of the Magi," is in the National Gallery. (See Vasari's *Lives of the Painters*, &c., and Lanzi's *History of Painting*.)

PESARO (anc. *Pisaurum*), a town in the Papal States, province of Pesaro-e-Urbino, stands on a well-wooded rocky eminence near the mouth of the Foglia, on the Adriatic, 19 miles E.N.E. of Urbino. It is surrounded by fortifications, and defended by a citadel. The streets are clean and well aired; and hence Pesaro presents a neater appearance than most Italian towns. It has a market-place, containing a fountain and a marble statue of Pope Urban VIII. Being the seat of a bishop, it contains a cathedral, not remarkable for its architecture; but this, as well as several other churches and some of the private houses, contains fine paintings. There are several convents and palaces. One of the latter, which formerly belonged to the dukes of Urbino, is now occupied by the papal legate. Among the public institutions of the place are a college, courts of law, a public library of 15,000 volumes (with museum and botanic gardens in connection with it), two hospitals, a foundling asylum, and a theatre. In the vicinity are several fine villas, one of which was the residence of Queen Caroline in 1818–19. The manufactures are few, consisting chiefly of silk and cotton stuffs; but the inhabitants are largely employed in trade, the principal articles of which are the agricultural produce of the surrounding country, such as wine, oil, and fruit, especially figs, reckoned the best in Italy. Pesaro has a harbour, but it is of small size. The ancient *Pisaurum* was a town of Umbria, where in 184 B.C. a Roman colony was founded; and after this it became a flourishing and important town, although the climate seems to have been then (though it is not now) unhealthy. It was occupied by Julius Cæsar after crossing the Rubicon in 49 B.C., and under the empire it was a place of some trade, where ships were built. The remains of an ancient bridge and theatre, as well as many inscriptions, still exist; and the town is supplied with water by an aqueduct, supposed to be the work of the Romans. Rossini, the celebrated musical composer, was a native of Pesaro. Pop. about 17,000.

PESARO-E-URBINO, a province of the Papal States, bounded on the N. and N.E. by the Adriatic, S.E. by the province of Ancona, S. by that of Perugia, and W. by that of Forli and by Tuscany; area, 1407 square miles. It entirely surrounds the republic of San Marino. The surface slopes gradually from the W., where it is mountainous, being divided from Tuscany by the range of the Apennines, which sends off several branches towards the sea, in which direction also the rivers of the province flow. The principal of these are the Foglia (anc. *Pisaurus*), the Metauro (anc. *Metaurus*), with its affluent the Cantiano; the Cesano; and the Misa. The mountainous parts of the province are generally barren; but the hills afford excellent pasturage, and their lower slopes are covered with vines, olives, and mulberry trees. The lower grounds are fertile and well cultivated, producing corn, pulse, hemp, flax, and various fruits. Cattle, sheep, and pigs are fed on the pastures in large numbers; and considerable attention is paid to bees and silk-worms,—the silk of Fossombrone, a town in the province, being considered the finest in Europe. The chief mineral found is coal, which is obtained in the vicinity of Pesaro. Pop. (1853) 257,751.

PESCE, NICOLA or COLA, a famous Sicilian diver, was born at Naples about the middle of the fourteenth century. His agility in swimming was the wonder of his contemporaries. They believed that he could live in the water as in his own proper element, and they surnamed him on that account *Pesce*, "The Fish." In fact, no feat ascribed to him was too huge for their gaping credulity to swallow. It was this exaggerated fame that became the occasion of the "Fish's" death. Frederick II., King of the Two Sicilies, hearing the astounding reports of his aquatic dexterity, resolved to subject it to a summary test. Accordingly a golden cup was thrown by the royal hand into the dreaded whirlpool of Charybdis, and the diver was desired to plunge after it, and win it as a prize. Twice he dived, and appeared again on the surface of the water. After disappearing the third time, he never came up. His body is said to have been cast ashore thirty miles distant. This fatal incident furnished Schiller with the groundwork of his famous ballad *Der Taucher*. (See Brydone's *Tour through Sicily and Malta*, London, 1773.)

PESCHIERA, a town of Austrian Italy, in the province of Mantua, stands at the foot of the Lago di Garda, where the Mincio, here crossed by a bridge, issues from the lake, 20 miles N. of Mantua. It is fortified, and defended by a small but strong Venetian citadel. There are here two churches and a custom-house. The inhabitants are chiefly employed in fishing. In 1848 the town surrendered, after an obstinate resistance, to the Sardinian army under Charles Albert. Pop. about 2500.

PESCIA, a town of Tuscany, province of Florence, in a beautiful country covered with groves of olives and mulberries, and studded with villas, convents, castles, and towers, 30 miles W.N.W. of Florence, on the Pescia, which is here crossed by two fine stone bridges. It is the seat of a bishop, and contains a fine modernized cathedral, with a painting by Raphael. The other churches are in no way remarkable. There are several palaces, schools, and charitable institutions. The inhabitants are employed in the manufacture of leather, paper, broadcloth, and silk; and some trade is carried on in silk, wine, and oil. Pop. (1852) 4900.

PESCO-PAGANO, a town of Naples, province of Basilicata, on the top of a lofty hill, 18 miles S.W. of Melfi, and 13 E.N.E. of Salerno. It has four churches and a convent, and manufactures of cotton and woollen goods and copper-wares. Pop. 4000.

PESHAWUR, or PESHAWER, a province of British India, in the Punjab, occupying the extreme N.W. corner of the empire. It lies between N. Lat. 33. 42. and 34. 30., E. Long. 71. 35. and 72. 42., and is bounded on the N.W. and S. by the Khyber, Mohmund, Swat, and Khuttuk hills, and on the E. by the Indus. Its length is 65 miles, breadth 50, area about 2324 square miles. Besides the Indus, it is watered by the Kabool river, which joins the Indus near Attock, and by the Swat, the Bara, and other affluents of the Kabool. The water of these rivers is used for irrigation, being conducted to the fields by numerous canals and small channels, from which it is raised by levers or Persian wheels. The country is very fertile, and this abundant supply of water renders it verdant at all seasons of the year. Two crops are raised annually; the principal produce being wheat, barley, maize, millet, and especially rice, which it produces in greater excellence than any other country in the world, and which is known by the name of Bara rice, from the river on whose banks it is grown. Vegetables, such as carrots, turnips, cabbages, onions, and others, are likewise raised; and an important part of the produce consists of what is called *paulaiz*, comprising melons and cucumbers of various kinds, pumpkins, and gourds. The castor-oil plant, the sugar-cane, ginger, tobacco, and cotton are among the other plants cultivated. Agriculture is well advanced; the plough has superseded the spade; and oxen are employed in treading out the corn, and in other labours. Plums, figs, peaches, pomegranates, and quinces are among the principal fruits that the country produces. The climate during the summer is extremely hot, though the occasional breezes from the mountains mitigate its sultriness. The province of Peshawur is traversed by the great route from Khorasan and Kabool to India, which crosses the moun-

tains by the Khyber pass; and there is also a grand trunk road which crosses the country, connecting the town of Peshawur with Lahore, along which the army of the Punjab is stationed. Forming part of the Punjab, Peshawur came into the possession of the British along with that country. Pop. 450,099.

PESHAWUR, the capital of the above province, on the Bara, about 18 miles E. of the eastern extremity of the Khyber pass, and 36 W. by N. of Attock, at an altitude of 1068 feet above the sea; N. Lat. 34., E. Long. 71. 38. It is defended by walls and a fort, which commands the whole of the town, the former having at intervals strong bastions. The fortress, which was erected by the Sikhs, occupies a square 220 yards each way, and has round towers at each corner The walls are all built of mud; and the place is surrounded by a moat and by a fausse-braie. The principal street of Peshawur, which stretches eastward from the Kabool gate, is broad, and lined on each side with houses of one storey. This is the only good street in the town, as the side lanes which diverge from it are very narrow, irregular, and dirty, and the houses mean. Peshawur contains three open places, that in the centre, which is of a circular form, being the finest part of the town. The houses in it are regularly built, and have in front of them a circle of acacias. On each side of this area is an arched gateway leading to a square, one of which is used as a market for grain, and the other for silk cloth, leather, and other articles. The town at one time contained numerous mosques, many of them being magnificent buildings; but they have been profaned by the Sikhs, and are now fast falling into decay. The manufactures are very few, consisting principally of *loongees*, or light-blue scarfs of cotton. In the adjacent country large quantities of salt are obtained; there are also two productive lead mines, and nitre and sulphur are likewise found. A considerable trade is carried on between Afghanistan and India by Peshawur; and this has been much increased since the British took possession of it, by the removal of all the restrictions that had been imposed by the Sikhs. Peshawur was founded by the Mogul emperor Akbar, from whom it obtained its name, which signifies "the advanced post," as it is the frontier city of India. It was formerly much more populous than at present; and in the beginning of this century it contained 100,000 inhabitants. Runjeet Singh took it after his victory over the Afghans at Noushera, and destroyed many of its finest buildings. Pop. 53,295, including 7706 Hindus.

PESTALOZZI, JOHANN HEINRICH, a distinguished educational reformer, was born at Zurich in Switzerland on 12th January 1746. He spent the greater part of a long life in advocating his theory of education, and in endeavouring to exemplify it in practice. The political oppression, moral depravity, and intellectual darkness which characterized the condition of the lower orders of society in his native land, had, at a very early period of his life, profoundly affected his benevolent and enthusiastic mind, and he had resolved to devote himself entirely to the amelioration of that condition. He first entertained the idea that he should best accomplish his object by becoming a political reformer; and, abandoning the clerical profession, for which he had been educated, he took to the study of the law. But the intensity of his application to his legal studies brought on a dangerous illness, and on the advice of his physicians he abandoned this profession also, burning all his manuscripts, and renouncing the study of books. It now occurred to him that he might effect his purpose by making agriculture the pivot of his educational operations. He accordingly went to live with a farmer of some repute, to learn practical agriculture, and to seek advice as to the best mode of prosecuting his plans. A successful experiment which this farmer made in cultivating madder on poor land induced Pestalozzi, in conjunction with a mercantile firm of Zurich, to purchase a tract of heath-land (the Neuhof) in Argovia, and make a similar experiment. But in this, the first important undertaking in which he engaged, Pestalozzi soon gave evidence of a singular deficiency in practical wisdom and tact. For example, he wasted a great deal of capital in erecting a dwelling-house and farm-buildings on his new estate. The experiment did not succeed, and the Zurich firm withdrew their capital with loss. Notwithstanding this failure, and the distress into which it threw him, he determined to go on with the execution of his plans. He wanted to combine with his agricultural operations a model industrial school for poor children. The idea of such a school is now familiar to us; it was then new. His plan met with the approval of many influential persons, and the school was commenced in 1775. For five years he devoted his whole time and energy to teaching and and training fifty destitute boys, literally gathered from the highways. But in the meantime, his own and his wife's fortune were going to the winds; he who was teaching others the conditions of success in life was neglecting some of the most obvious of those conditions in the management of his own affairs. By the end of the period mentioned he had brought himself down to the pecuniary level from which he was endeavouring to raise his pupils.

Nevertheless, we reap the fruits of Pestalozzi's labours in the numerous industrial and reformatory schools which have been established in our own country. It was Pestalozzi's poor-school that suggested to De Fellenberg the one which he established on his estate of Hofwyl; and which, under the skilful management of Wehrli, gained a success which definitively settled the question of the practicability of the idea. Pestalozzi himself, visiting Hofwyl some thirty years after the breaking up of his own school, acknowledged that in Wehrli's school he saw his idea realized. The success of Wehrli's school led to the establishment of many others in Switzerland and other countries. "In the orphan schools which emanated from Pestalozzi and De Fellenberg we found," say Sir James Kay Shuttleworth and Mr Tufnell, in their report on the Battersea normal school, "the type which assisted us in our subsequent labours. In walking with M. De Fellenberg through Hofwyl, we listened to the precepts which we think most applicable to the pauper class. In the normal school of the canton of Thurgovia (at that time conducted by Wehrli), and in the orphan schools of St Gall and Appenzell, we found the development of those principles so far successful as to assure us of their practical utility." Pestalozzi's countrymen could not have raised any memorial to him more appropriate than the orphan school which they founded at Olsberg in Argovia, after the commemoration of the hundredth anniversary of his birthday in 1846. If such establishments are not always successful in a pecuniary point of view, even with the accumulated experience which we now possess, it should make us judge the more leniently the failure of the man who grappled with the difficulties of the task for the first time.

For eighteen years after the breaking up of the Neuhof poor-school, Pestalozzi did not engage in any educational undertaking. Some of his most important works, however, were written during this period; among others, *The Evening Hour of a Hermit*, a series of educational aphorisms very similar to the *Didactica Magna* of Comenius; and *Leonard and Gertrude*, a dramatic novel pourtraying the actual condition of the Swiss peasantry and his own ideal of a good home and school education for the people. The latter work established his reputation, and exercised an important influence on the progress of popular education throughout Switzerland and Germany. A translation of this work is a desideratum in our language. In 1798 he was called upon by the Swiss Directory to go to Stanz in Unterwalden, and take charge of a number of children

left destitute after the terrible punishment inflicted on that resisting canton by the French army of occupation. Without a moment's hesitation, he left his family, and for nine months he acted as the sole teacher and superintendent of eighty orphan boys of the lowest grade of society, in an old desolate cloister, with no books, maps, or other appliances of instruction, and with no assistance of any kind, save such as could be rendered him by an old housekeeper. With these children he made many new experiments in education. Among other plans which he tried were those of monitors and simultaneous reading and speaking. The monitorial plan, however, is as old as Comenius, and the simultaneous plan had previously been introduced into the Austrian schools. The circumstances were highly favourable to the application of his general theory, which required all instruction to be based on real objects and familiar daily occurrences; and many of his lessons, secular and moral, appear to have been fine specimens of intuitive teaching. That, in concentrating his mind upon the development of his own plans, he should sometimes overlook the peculiarity of the circumstances, and constantly neglect matters that appeared to him of minor importance, was to be expected. His extraordinary efforts in this difficult and harassing position had well nigh brought him to the grave, when the progress of events connected with the war compelled him to give up the school. He went up into the Bernese Oberland to recruit his exhausted energies. His next important undertaking was the foundation of an educational institution for the practical application of his method. He had for some time past sought assistance from the Helvetian government towards the attainment of this object, which he regarded as one of national importance. At length the government gave him the use of the castle of Burgdorf, and in those premises he opened his institution in 1800. The institution was removed successively to Münchenbuchsee, near Hofwyl, and to Yverdun, in the canton of Vaud. In the very first years of its existence it attracted much notice, owing in great measure to an account of his plans, which Pestalozzi published under the title, *How Gertrude Teaches her Children.* Subsequently it became, in the language of one of Pestalozzi's eulogists, a "European training institution for teachers and educators." The internal management of the institution, however, appears to have been anything but satisfactory. His own want of governing and practical power necessarily compelled him to place a leading share of the management in the hands of one or other of his assistants, among whom, accordingly, a contention arose which proved fatal to the welfare of the institution and the happiness of its venerable founder, who had the mortification of seeing his enterprise going to wreck, and himself standing powerless at the helm. The institution was finally broken up in 1825. A poor-school, which he had founded at Clindy, near Yverdun, in 1818, had failed from similar mismanagement. He made an attempt to transplant this school to his estate of Neuhof, in the hope that it might succeed better away from "the institution." But the building which he erected for the purpose stood incomplete and unoccupied at the time of his death. This event happened on 17th February 1827. During the last two years of his life he wrote his autobiography in two works—*The Song of the Dying Swan,* and *The Fortunes of My Life.* In these works he reviews his various educational undertakings, and endeavours to trace the causes of their failure. As the works enter very fully into the details of the personal quarrel at Yverdun, they are variously represented by his biographers according as these side with one or other of the parties; and, for the same reason, they are now of very little interest to the world. Shortly before his death he said: "I forgive my enemies; may they find peace, now that I go to eternal rest. I should like to have lived another month, to have completed my last labours; but I again thank God, who in his providence calls me away from this earthly scene. And you, my children, remain in quiet attachment to one another, and seek for happiness in the domestic circle."

Pestalozzi's general theory of education may be stated in few words. He held that all our knowledge is derived, in the first instance, from the perceptions of the senses, and that therefore all instruction should be based upon the observation of real objects and occurrences; or, in other words, should proceed, by a process of induction, from the concrete to the abstract, from the known to the unknown. He further held that the object of primary education was to give a general and harmonious cultivation to the faculties of the mind, not to communicate technical knowledge. He accordingly required that all instruction should be presented to the pupil in a form corresponding to the process of intellectual development, by which the mind rises from the perceptions of the senses to clear ideas; and that the adaptation of different subjects for the purposes of elementary instruction should be judged of by the amount of educative power which they respectively possess. (See NATIONAL EDUCATION.)

Pestalozzi belongs to the modern or "realistic" school of educators, the general tendency of which is two-fold—(1.) As regards the *matter* of instruction, to supersede the languages and literature of Greece and Rome by the mother-tongue and practical knowledge; and (2.) As regards the *manner* of instruction, to supersede the analytic and experimental method by a synthetic and demonstrative one. The most eminent men of this school before Pestalozzi were Rousseau, Locke, and Comenius. Its origin is distinctly traceable to the influence of Bacon's method of philosophy.

Like Lord Bacon, Pestalozzi did very little towards the practical application of his own principles. Some of his attempts to apply them to individual branches of instruction were singularly at variance with them. This was the case with his treatment of the instruction in language, as explained in his work *How Gertrude Teaches her Children* He divides the instruction into—1. Lessons on Sounds; 2. Lessons on Names; 3. Lessons on Language. 1. "The spelling-book (he says) must contain the entire range of sounds of which the language consists, and portions of it should be repeated daily in every family, not only by the child that is going through the exercises to learn how to spell, but also by mothers, within hearing of the child in the cradle, in order that these sounds may, by frequent repetition, be so deeply impressed upon the memory of the child, even while it is yet unable to pronounce a single one of them, that they shall never be forgotten. No one imagines to what a degree the attention of infants is aroused by the repetition of such simple rounds as ba, ba, ba; da, da, da; ma, ma, ma; la, la, la, &c.; or what a charm such repetition has for them." 2. Lessons in names (he says) consist in giving the children lists of the names of the most important objects in all three kingdoms of nature, in history, in geography, and in the pursuits and relations of mankind. 3. In the "lessons in language" he classifies what is to be learned under the following heads:—Geography, history, physics, natural history, and physiology. Each of these five heads he divides again into forty subdivisions. He now proceeds to give lists of words in all these subjects in alphabetical order, which lists are to be impressed upon the children's memories "till it is impossible any should be forgotten." Afterwards, this alphabetical nomenclature is to be transformed into a "scientific" one. He gives the following examples:—"One of the subdivisions of Europe is Germany: the child is first of all made well acquainted with the division of Germany into ten circles; then the names of the towns of Germany are placed before him, at first in mere alphabetical order, for him to read, but each of these towns is previously marked with the number of the circle in which it lies. As soon as the child can read the names of the towns fluently, he is taught the connection of the numbers with the subdivisions of the main heads; and in a few hours he is able to determine the place of the entire number of German towns in these subdivisions." And this is what Pestalozzi calls "changing the alphabetical into a scientific nomenclature." (The quotations are taken from Mr Tilleard's translation of Raumer's *Life of Pestalozzi*) Thus, again, with his so-called exercises in observation; or object-lessons. The type of such lessons was pretty nearly this: Suppose that the lesson was on a piece of sponge. The teacher, holding up the specimen before the boys, would sing out in a high monotone such sentences as the following, requiring the class to repeat each sentence in unison three times:—"That is sponge." "Sponge is an animal product." "Sponge is amorphous." "Sponge is porous." "Sponge is absorbent," &c. Nothing approaching to an elucidation of the scientific principles involved in common objects and processes appears to have been attempted in these lessons. Indeed Pestalozzi says, with the utmost candour, when treating of the instruction in language, "I never pretended to teach any art or

Pestalozzi.

science; in fact, there is not one with which I myself am acquainted. My only object is to facilitate generally the acquisition of the elements of all the arts and sciences, and to give to the neglected and abandoned classes of my countrymen open access to the stores of human civilization."

Pestalozzi was perhaps most successful in the application of his principles to the instruction in arithmetic; but even his method of teaching this subject counteracted them to a large extent The aim of the Pestalozzian arithmetic is to lead children to observe for themselves the properties and relations of numbers, as shown upon the various tables made use of. If the spirit of the method is realized by the master, nothing can be more important than the influence which it has upon his instruction in this subject. It teaches him to base all his explanations upon first principles, instead of condemning his pupils to work from prescribed rules, of which they do not understand the reasons. He thus gives them the power of deducing arithmetical results for themselves, and scope for the exercise of their judgment as well as of their memory. Treated in this common-sense manner, arithmetic is invaluable as a mental discipline; and, from being a dry task, it is rendered an interesting exercise to the children; for the child is always gratified by any instruction that appeals to its reasoning powers. But Pestalozzi caused a manual to be prepared in which the exercises to be done upon the tables were printed at full length, and the boys were made to go through the whole series, under the care of an assistant master, until the repetition became one monotonous sing-song, not requiring the slightest thought. One of his pupils gives the following account of the way in which he himself taught this subject:—"For the ciphering, we had between every two scholars a small table pasted on mill-board, on which, in quadrangular spaces, were marked dots, which we had to count, to add together, to subtract, to multiply, and divide by one another. It was out of these exercises that Krüsi and Buss constructed, first the Unity Table, and afterwards the Fraction Tables. But as Pestalozzi only allowed the scholars to go over and to repeat the exercises in their turns, and never questioned them nor set them tasks, these exercises, which were otherwise very good, remained without any great utility. He had not sufficient patience to allow things to be gone over again, or to put questions; and in his enormous zeal for the instruction of the whole school, he seemed not to concern himself in the slightest degree for the individual scholar."

The truth of the Pestalozzian maxim, that the mind grasps the concrete more readily than the abstract, has received a curious confirmation in the extensive imitation which Pestalozzi's methods, though opposed to his principles, have met with at the hands of his admirers. It is but too true that teachers, in common with other mortals, are ever more ready to adopt plans than to adopt principles. The Pestalozzian arithmetic was introduced at a very early period, into the Dublin model schools by the Irish Commissioners, who published an edition of the Manual of Exercises for the use of their teachers. A somewhat modified form of their Manual was published in 1844, under the sanction of the Committee of Council on Education, for the use of teachers in Great Britain. That work, however, was superseded by Tate's *First Principles of Arithmetic*; a work which gave a more correct and comprehensive application of Pestalozzian principles to the subject of arithmetic; and which has done much towards completing a radical reform in the teaching of this subject in our elementary schools. The Pestalozzian object-lessons have been widely imitated in this country. These lessons, however, are gradually giving place to lessons on the science of common things more in accordance with Pestalozzi's own principles. Pestalozzi's method of instruction in language does not appear to have been adopted, as a whole, by any of his followers. But the greater part of it is embodied in Scherr's method of teaching reading, which is extensively used by Swiss teachers.

While Pestalozzi's personal influence on the methods of teaching particular subjects has thus been small, he has, through his profound principles, exerted a greater influence on elementary education than any other man in recent times. That the visible improvement in teaching which has been made of late years in England is in a great measure due to his influence, there can be little doubt. At the Battersea normal school, from which much of that improvement emanated, Sir James Kay Shuttleworth propounded the general principles of a synthetic and demonstrative method, confessedly based upon the Pestalozzian idea; and those principles were ably applied to various branches of elementary instruction by his coadjutors, whose text-books are now in the hands of many teachers. The Home and Colonial School Society, also, by whom so much has been done for the improvement of infant school education, have professedly been guided by the principles of Pestalozzi.

The influence of the personal character of this great and good man has been very remarkable. His spirit has been infused into whole generations of teachers in his native land, and, through individual disciples, has been communicated far and wide over the whole civilized world. His enthusiastic love for children; his zealous devotion to the interests of his countrymen and of humanity; his unwavering faith in the efficacy of education (under God's blessing) for the regeneration of the lower classes of society; his unflinching courage in urging upon rulers and all set in authority the sacred duty of providing for the poor a more Christian institution than either the workhouse or the gaol, above all, the intense concentration of energy and purpose with which he pursued his object through a long and often unhappy life,—these features in his character demand our highest admiration, and place Pestalozzi in the foremost rank of distinguished schoolmasters. (J. T—D)

Pesth.

PESTH, or PEST, the most populous town of Hungary, capital of an administrative territory of the same name, stands on level ground on the E. bank of the Danube, immediately opposite Buda, with which it is connected by a fine suspension-bridge, 135 miles E.S.E. of Vienna. Besides the original or old town in the centre, there are four suburbs, known by the names of Leopold, Theresa, Joseph, and Francis Town respectively. The most of the town being of modern erection, is regularly and handsomely built: the streets are broad, straight, and well paved; and many of the shops, in splendour and decorations, are little inferior to those of Vienna. The principal and most frequented streets in the town are the Herren, Waitzner, Dorotheen, and Grosse-Bruck Gasse. The streets of Pesth present a strange scene, on account of the mixture of grandeur and barbarism that is to be seen in them, and the strange contrasts between the magnificent carriages, with their liveried attendants, and the troops of wild horses or herds of oxen, with their wild-looking drivers clad in sheepskins. Along the bank of the Danube runs a broad quay, which forms one of the principal ornaments of the town, as it is paved and terraced, though till recently it was little better than a muddy tract of ground. It is lined for nearly a mile and a half with lofty and handsome buildings, brilliantly whitewashed, among which is an elegant theatre. There are several squares in the town, one of which, the new market-place, is remarkable for its size, and for the elegance and regularity of the buildings that surround it. The public buildings of Pesth are not very numerous nor fine. One of the most conspicuous is an enormous edifice called the Neugebaude, erected in 1786 by the Emperor Joseph II. Its original design is not known, though it is said by the Hungarians to have been intended for the confinement of some of their chief nobles; but it is now used for barracks and artillery magazines. It is four storeys high, and incloses a central court of great extent, which has entrances at the four corners. The university building, and the church in connection with it, are worthy of notice; and the parish church is a fine edifice in the Gothic style. The churches in the town, however, are not numerous in proportion to the population, nor are they remarkable for architectural beauty. They belong to a great number of different sects; for the Roman Catholic, the United Greek, the Separatist Greek, the Lutheran, and the Reformed Church have each places of worship; and there are also several synagogues. The services in these churches are performed in the Latin, Greek, German, Hungarian, and Slavonic languages. The town-hall of Pesth, erected in 1844, has a peculiar tower; and there is a county-hall, recently rebuilt and enlarged, in which the nobles of the county used to meet for discussion and the election of magistrates. The National Museum, devoted almost exclusively to Hungarian articles, is a magnificent building, and contains a large collection of Roman and mediæval remains, arms, and other relics of distinguished persons, objects of natural history, a gallery of paintings, and a library of 20,000 vols. and 2000 MSS. Besides the university (which is described under the article HUNGARY), Pesth contains several other educational institutions. A Hungarian Academy, on the plan of the French Institute, a Lutheran and a Catholic gymnasium, an English school for young ladies, a normal

school, an institution for the blind, are the most important of these; and there is also a botanic garden, an observatory, as well as several hospitals and benevolent establishments. The Ludoviceum, a fine building at the S.E. end of the town, was erected in 1837 as a military school; but it has never been used for that purpose, and is now employed as a military hospital. Pesth contains several theatres; in one of which, the National, an elegant edifice, the performances are entirely in the Hungarian language. Besides these, the places of amusement in the town consist of coffee-houses and public walks, the principal of the latter being the Stadtwaldchen, which is situated to the north of the town. Not far from Pesth is the field of Rakos, which is famous in Hungarian history as the place where the national assembly of the Magyars was held in the open air, from the year 1268 to 1525. Horse-races are now held annually on this plain. Pesth is the seat of the principal courts of law in Hungary, though not the capital of that country. These formerly consisted of a Royal Court, having jurisdiction over the district courts, and from which an appeal lay to the Septemviral Court, the highest tribunal in the kingdom. Since 1852, however, Hungary has been made subject to the Austrian law, and the supreme courts now have their seat in Vienna, while Pesth has only an *oberlandes-gericht*, a *landes-gericht*, and a tribunal of commerce. The manufactures of Pesth are extensive, consisting of silk, cloth, leather, straw hats, gold and silver articles, and especially meerschaum pipe-bowls, which are brought in a rough form from Constantinople, and are here prepared for the German markets. The trade is very considerable, and consists principally of corn, wine, timber, cattle, and wool. Besides weekly markets, there are four annual fairs held here, which are visited by upwards of 30,000 strangers, and at which transactions to the extent of more than L.3,000,000 take place. Pesth carries on a considerable trade on the Danube by steam-boats. The modern town is believed to occupy the site of the ancient *Contra Acincum*, which is also called *Pession* by Ptolemy. Although it was built by Arpad, and walled in the thirteenth century, yet till within the last hundred years it was a place of very little importance, having met with a long series of calamities, in having been taken by the Turks no fewer than five times. It has also frequently suffered from inundations of the Danube, caused by the obstruction of the ice below the town. The most destructive of these floods took place in March 1838, when a great part of Pesth was laid under water, and 2281 houses in the town, besides 207 in Buda, and 1500 in the vicinity, were totally destroyed. That calamity has, however, given occasion for the rebuilding of the town in a much superior style to that which formerly existed. In April 1849, Pesth being in the hands of the Hungarians, while Buda was occupied with a garrison by the Austrian general Hentzi, a severe contest began between the two parties. On the 4th of May, Görgei, with an army of 40,000 Hungarians, occupied the heights above Buda, and began to bombard that town; while the Austrians, in their turn, directed their artillery against the lower city of Pesth. The latter bombardment destroyed many of the public buildings, and did so much damage that most of the inhabitants took refuge in the Stadtwäldchen. On the night of the 16th May the Hungarians made an unsuccessful attack on Buda; but on the 20th the place was taken by assault, after an obstinate and bloody struggle. Pesth is connected by railways, on the one hand with Vienna, and on the other with Debreczin, Grosswardein, and Temesvar, in the E. and S. of Hungary. Pop. (1851), exclusive of the military, 106,379.

The administrative territory of Pesth, which is bounded on the N. by those of Pressburg and Kaschau, E. by that of Grosswardein, S. by the Voivodina of Servia, and W. by the territory of Oedenburg, comprises, besides the district of Buda and Pesth, nine counties, and has an area of 14,094 English square miles.

PETALISM. See Ostracism.

PETAU, Denis (better known under the Latinized form of his name, *Dionysius Petavius*), a French Jesuit of great erudition, was born at Orleans in the year 1583. To the study of the belles-lettres he joined that of the mathematics; and afterwards applied himself to a course of philosophy, which he commenced in the college of Orleans, and finished at Paris. He subsequently maintained theses in Greek, which was as familiar to him as Latin; and the Latin, it is said, he understood better than he did his vernacular language. When he was pretty well advanced in his studies, he had free access to the king's library, which he often visited on account of the Latin and Greek manuscripts. Amongst other advantages which attended his literary pursuits, may be reckoned the friendship of Isaac Casaubon, whom Henri IV. called to Paris in 1600. It was at Casaubon's instigation that Petavius, though then very young, undertook an edition of the works of Synesius, in which he corrected the Greek from the manuscripts, translated what yet remained to be translated into Latin, and wrote notes upon the whole. He was only nineteen years of age when he was made professor of philosophy in the university of Bourges; and he spent the following years in studying the ancient philosophers and mathematicians. In 1604, when Morel, professor of Greek at Paris, published the works of St Chrysostom, some part of Petavius' labours on Synesius were added to them; and from the title we learn that he then took the name of *Pætus*, which he afterwards changed into *Petavius*. His own edition of the works of Synesius did not appear till the year 1612. He entered into the Society of the Jesuits in 1605, became a zealous advocate of the Church of Rome, and rejoiced in criticising and assailing its adversaries. He was bitter against Joseph Scaliger; nor did he even spare his friend Casaubon whenever the latter came in his way. Muratori regarded Petau as "the restorer of dogmatic theology." He excelled likewise in chronology. His great work on that subject, entitled *Rationarium Temporum*, is an abridgment of universal history from the earliest times till the year 1632, arranged in chronological order, with references to proper authorities; and it was improved by Perizonius and others, who made several additions to it after his death. Petau died at Paris in 1652, aged sixty-nine.

PETCHORA, a river of European Russia, rises in the Ural Mountains, on the borders of the governments of Perm and Vologda, flows at first westwards, and then through extensive flat moors in a curve towards the N., traversing the governments of Vologda and Archangel. After a course of 1300 miles, having acquired a great breadth, it falls into the gulf of Pustoserssk by several mouths. For nearly nine months in the year this gulf is blocked up with ice. Among the numerous affluents of the river, the largest are the Ussa from the right, and the Ishma from the left.

PETER (originally *Simeon* or *Simon*, שמעון, called also, by a rendering of the Greek Πετρος into the corresponding word in the Aramaic dialect spoken in Palestine in the days of our Lord, *Cephas*, כיפא, John i. 42), one of the twelve apostles, and author of two Epistles in the inspired canon. He was a native of Bethsaida in Galilee, and was the son of a certain Jonas, or John; whence he is named on one occasion in the gospel history *Simon Barjona*, that is, son of Jona (Matt. xvi. 17). At the time of his introduction to Christ he was married, and was resident at Capernaum with his family. Along with his brother Andrew, he followed the occupation of a fisherman on the Sea of Galilee. It is probable that before they became known to Christ they were both disciples of John the Baptist. That Andrew was so, we are expressly informed by the

St. Peter. evangelist John; and as his brother seems to have been much of the same mind with him on religious matters, it is extremely likely that he was so likewise. Their becoming known to Christ was owing to John's pointing him out on the day after his baptism to Andrew and another disciple (probably the evangelist John), as "the Lamb of God," on which they immediately followed Christ, and spent some time in receiving his instructions. Shortly after this, Andrew finding Simon, carried him to Christ, who, on receiving him as his disciple, bestowed upon him that surname by which he has since that time been most commonly designated: "When Jesus beheld him he said, thou art Simon the son of Jona; thou shalt be called Cephas, which is by interpretation a stone (πετρος)." After this interview the two brothers seem to have returned to their usual occupation for a season, as we have an account in Matthew (iv. 18–20) of their being summoned from that occupation by Christ on a subsequent occasion, posterior to his temptation in the wilderness, and to the commencement of his public ministry as a religious teacher. From this time forward they were his devoted and admiring followers. In the course of the evangelical history several anecdotes of Peter are incidentally recorded, for the purpose, doubtless, principally of illustrating the character and teaching of our Lord, but which tend also to throw light upon the history and character of his attached disciple. Such are the accounts furnished by the evangelists of his walking upon the agitated waters of the Sea of Galilee to meet his master (Matthew xiv. 22, ff.; Mark vi. 45, ff.); of his bold and intelligent avowals of the undoubted Messiahship of Jesus, notwithstanding the difficulties which he, along with the rest of the disciples, felt in reconciling what they saw in him with what they had fondly expected the Christ to be (Matthew, xvi. 13–20); of his rash but affectionate rebuke of his Lord for speaking of suffering and death as in prospect for him, and as forming a necessary part of his mediatorial work (Matthew xvi. 21–23); of his conduct in first rejecting, with an earnestness bordering on horror, the offer of Christ to wash his feet, and then, when the symbolical nature of that act had been explained to him, his over-ardent zeal that not his feet only, but also his hands and his head, might be washed (John xiii. 4, ff.); of his bold and somewhat vaunting avowal of attachment to his Master, and his determination never to forsake him, followed by his disgraceful denial of Jesus in the hour of trial (John xiii. 36, 37; Mark xiv. 29, &c.); of his deep and poignant contrition for this sin (Matthew xiv. 72); and of his Lord's ample forgiveness of his offence, after he had received from him a profession of attachment as strong and as frequently repeated as his former denial of him (John xxi. 15–18). From these notices it is easy to gather a tolerably correct conception of the predominating features of the apostle's character up to this period. He seems to have been a man of undoubted piety, of ardent attachment to his Master, and of great zeal for what he deemed his Master's honour, but at the same time with a mind rather quick than accurate in its apprehensions, and with feelings rather hasty in their impulse than determined and continuous in their exercise. Hence his readiness in avowing his opinions, and his rashness in forming them; and hence also the tendency which beset his honest openness to degenerate into bravado, and his determinations of valour to evaporate into cowardice at appalling forms of danger. His fall, however, and his subsequent restoration, connected as these were with the mysterious events of his Master's crucifixion and resurrection, and with the new light which had by them been cast around his character and work, produced a powerful change for the better upon the apostle's mind. From this time forward he comes before us under a new aspect. A sober dignity and firmness of purpose have displaced his former hasty zeal; sagacity and prudence characterize his conduct; and whilst his love to his Master shows no symptom of abatement, it displays itself rather in active labour and much-enduring patience in his service, than in loud protestations or extravagant exhibitions of attachment. In the subsequent Scripture history he is presented to us as the courageous herald of the kingdom of Christ, by whose mouth the first public declaration of salvation through the crucified Jesus was made to the people; by whose advice and counsel the early churches were planted and governed; and by whom the prejudices of Judaism were first fairly surmounted, and the gospel preached in all its universal freeness to the Gentile world. The Acts of the Apostles contain recitals of many interesting incidents which befell him whilst engaged in those efforts. Of these, the chief are his imprisonment and trial before the Sanhedrim, for preaching Christ, and his bold avowal of his determination to persist in that work (Acts iv. 1–22); his miraculously inflicting the punishment of death on the infatuated couple who had dared to try an experiment upon the omniscience of the Holy Ghost (v. 1–11); his visit to Samaria, and rebuke of Simon Magus, who deemed that the miracles of the apostle were the work of some deep magic spell of which he had not yet become possessed, and which consequently he was desirous of purchasing from Peter (viii. 14–24); the vision by which he was taught that the ancient ritual distinctions between clean and unclean had been abolished, and thereby prepared to attend on the summons of Cornelius, to whom he preached the gospel (x. 1–48); his apprehension by Herod Agrippa, and his deliverance by the interposition of an angel, who opened for him the doors of his prison, and set him free (xii. 3–19); and his address to the council at Jerusalem, on the occasion of a request for advice and direction being sent to the church there by the church in Antioch, in which he advocated the the exemption of Gentile converts from the ceremonial institutes of the law of Moses (xv. 6–11). In all these incidents we trace the evidences of his mind having undergone an entire change, both as to its views of truth and impressions of duty, from what is displayed by the earlier events of his history. On one occasion only do we detect something of his former weakness, and that strangely enough in regard to a matter in which he had been the first of the apostles to perceive, and the first to recommend and follow, a correct course of procedure. The occasion referred to was his withdrawing, through dread of the censures of his Jewish brethren, from the Gentiles at Antioch, after having lived in free and friendly intercourse with them, and his timidly dissembling his convictions as to the religious equality of Jew and Gentile. For this Paul withstood him to the face, and rebuked him sharply, because of the injury which his conduct was calculated to produce to the cause of Christianity. With this single exception, however, his conduct seems to have been in full accordance with the name which his Master had prophetically bestowed on him when he called him Simon the Rock, and with the position which Paul himself assigns to him, at the very time that he recounts his temporary dereliction, as one of the "pillars of the church."[1]

Thus far we are enabled, from the inspired documents,

[1] Gal. ii. 9–14. The circumstance of Peter's having submitted to a rebuke from Paul is so fatal to the pretensions which have been urged in favour of his supremacy over the other apostles, that from a very early age attempts have been made to set aside its force by the hypothesis that it is not of Peter the apostle, but of another person of the same name, that Paul speaks in the passage referred to. (*Conf.* Euseb. *H. E.* i. 13.) This hypothesis, however, is so plainly contradicted by the words of Paul, who explicitly ascribes apostleship to the Peter of whom he writes, that it is astonishing how it could have been admitted even by the most blinded zealot. See ver. 8, 9.

St. Peter.

to trace the history of this apostle; but for what remains we must be indebted to evidence of a less explicit and certain character. The testimony of several of the ecclesiastical writers, corroborated by the phraseology employed by the apostle himself in the salutation of his first Epistle, makes it highly probable that at some period of his official life he performed an extensive missionary tour throughout those districts, to the converts to which his Epistles were addressed. "It appears," says Origen, "that Peter preached to the Jews in the dispersion, in Pontus, Galatia, Bithynia, Cappadocia, and Asia."[1] A less certain tradition reports the apostle as having, towards the close of his life, visited Rome, become bishop of the church in that city, and suffered martyrdom in the persecution raised against the Christians by Nero. The importance of these points in connection with the claims urged by the Catholics on behalf of the supremacy of the Pope, has led to a careful and sifting examination of the accuracy of this tradition, the result of which seems to be that, whilst it is admitted as certain that Peter suffered martyrdom, in all probability by crucifixion,[2] and as probable that this took place at Rome, it has, nevertheless, been made pretty clear that he never was for any length of time resident in that city, and morally certain that he never was bishop of the church there.[3] By some an attempt has been made to obtain the support of the apostle's own testimony in favour of his having at one period resided at Rome, by interpreting the words "the church that is at Babylon," the salutations of which he sends to those to whom he wrote his first Epistle, as applying to the church at Rome; an attempt which Dr Campbell justly stigmatizes as "poor, not to call it ridiculous." Even if we admit that at the time when this Epistle was written it was understood amongst the Christians that Babylon was the prophetical name for Rome, an admission, however, which is entirely unsupported by evidence, it would remain unexplained why the apostle, in such a mere matter-of-fact affair as the communication of the friendly salutations of one church to another, should have employed the obscure and symbolical language of prophecy, when his meaning could have been so much more distinctly conveyed by a simple statement. This would be the more inexplicable, that the style of Peter is remarkably plain and perspicuous throughout the entire Epistle. It seems much more consistent, therefore, with rational principles of interpretation, to understand the statement literally of Babylon in Egypt, in which city, as we learn from Josephus, there was a great multitude of Jews (ἐνθα και πληθος ἦν Ἰουδαιων, *Ant. Jud.*, l. xv., c. ii., sect. 2; see also c. iii., sect. 1), and to which, consequently, it is almost certain, that at some period of his life, "the apostle of the circumcision" (Gal. ii. 8) must have paid a visit.

The assertion, that St Peter was bishop of Rome, is connected with another by which the claims of the Papacy are sought to be established,—namely, that to him was conceded a right of supremacy over the other apostles. In support of this, an appeal is made to those passages in the Gospels where declarations supposed to imply the bestowal of peculiar honour and distinction on Peter are recorded as having been addressed to him by our Lord. The most important of these are, "Thou art Peter, and on this rock will I build my church" (Matt. xvi. 18); and "Unto thee will I give the keys of the kingdom of heaven," &c. (Matt. xvi. 19). At first sight these passages would seem to bear out the assumption founded on them; but upon a more careful investigation it will be seen that this is rather in appearance than in reality. The force of both is greatly impaired for the purpose for which Catholics produce them, by the circumstance, that whatever of power or authority they may be supposed to confer upon Peter must be regarded as shared by him with the other apostles, inasmuch as to them also are ascribed in other passages the same qualities and powers which are promised to Peter in those under consideration. If by the former of these passages we are to understand that the church is built upon Peter, the apostle Paul informs us that it is not on him *alone* that it is built, but upon *all* the apostles (Ephes. ii. 20); and in the book of Revelation we are told, that on the twelve foundations of the New Jerusalem (the Christian church) are inscribed "the names of the *twelve apostles of the Lamb*" (chap. xxi. 14). As for the declaration in the latter of these passages, it was in all its essential parts repeated by our Lord to the other disciples immediately before his passion, as announcing a privilege which, as his apostles, they were to possess in common (Matt. xviii. 18; John xx. 23). It is, moreover, uncertain in what sense our Lord used the language in question. In both cases his words are metaphorical; and nothing can be more unsafe than to build a theological dogma upon language of which the meaning is not clear, and to which, from the earliest ages, different interpretations have been affixed. And, finally, even granting the correctness of that interpretation which Catholics put upon these verses, it will not bear out the conclusion they would deduce from them, inasmuch as the judicial supremacy of Peter over the other apostles does not necessarily follow from his possessing authority over the church. On the other side, it is certain that there is no instance on record of the apostle's having ever claimed or exercised this supposed power; but, on the contrary, he is oftener than once represented as submitting to an exercise of power upon the part of others, as when, for instance, he went forth as a messenger from the apostles assembled in Jerusalem to the Christians in Samaria (Acts viii. 14), and when he received a rebuke from St Paul, as already noticed. Whilst, however, it is pretty well established that Peter enjoyed no judicial supremacy over the other apostles, it would perhaps be going too far to affirm that no dignity or primacy whatsoever was conceded to him on the part of his brethren. His superiority in point of age, his distinguished personal excellence, his reputation and success as a teacher of Christianity, and the prominent part which he had ever taken in his Master's affairs, both before his death and after his ascension, furnished sufficient grounds for his being raised to a position of respect and of moral influence in the church and amongst his brother apostles. To this some countenance is given by the circumstances, that he is called "the first," πρωτος, by Matthew (chap. x. 2), and that apparently not merely as a numerical, but as an honorary distinction; that when the apostles are mentioned as a body, it is frequently by the phrase, "Peter and the eleven," or, "Peter and the rest of the apostles," or something similar; and that when Paul went up to Jerusalem by Divine revelation, it was to Peter particularly that the visit was paid. These circumstances, taken in connection with the prevalent voice of Christian antiquity, would seem to authorize the opinion that Peter occupied some such position as that of προεστως, or president in the apostolical college, but without any power or authority of a personal kind over his brother apostles.[4]

St. Peter

The extant writings of the apostle Peter are confined to two brief Epistles, of which the former has been universally admitted as genuine, whilst the latter has by many been re-

jected as spurious. The grounds of this rejection, however, are extremely insecure, as they depend chiefly upon nice distinctions and analogies of style between the two Epistles, which are seldom drawn with such unerring accuracy as to induce us to attach very much weight to them.[1] The persons to whom these Epistles were addressed were converted Jews scattered over the districts enumerated by the apostle in the commencement of the first of them. The Epistles themselves are characterized by great vigour of conception, warmth of feeling, and force of eloquence. The style is glowing and rapid, approaching at times to vehemence; and the sentiments are of the most elevated description. The exhortation to holiness with which the second chapter of the first Epistle concludes is perhaps unequalled in the New Testament for the appropriateness of its sentiments, the beauty of its appeals, and the concentrated energy and rapid flow of the style; nor would it be easy to find any passage, either in sacred or profane literature, that should surpass in vividness of description and power of expression the prophetic view of the end of the world with which, towards the conclusion of the second Epistle, he enforces his exhortation to holy conversation and godliness. In both Epistles we trace the characteristic ardour and the elevated piety of their author, and of both we may justly say, in the language of the excellent Leighton, that they are eminently adapted "to establish Christians in believing, to direct them in doing, and to comfort them in suffering, often setting before them the matchless example of the Lord Jesus, and the greatness of their engagement to follow him." "Peter," says a recent German writer, "has, according to his own fundamental trait, conveyed the character of enduring firmness from the life of Christ to the church. The shadow sides of this fundamental trait have been represented in the Romish hierarchy; the light sides in the pure form of the church confessions, the church institution, order, discipline, and manifestations." (Lange, *Das Apostol. Zeitalter*, i. 357. See also Neander, *Gesch. d. Pfl. und Leit. der Christ. Kirch.*, p. 443-463, Eng. tr., vol. i., p. 368-383; Hug's *Introduction* by Fosdick, p. 635; Davidson's *Introduction to the New Testament*, vol. iii., &c.) (W. L. A.)

Peter *the Hermit*, the apostle of the first Crusade, was descended from a good family, and was born at Amiens in France about the middle of the eleventh century. The first part of his career was passed in obscurity. He served without distinction in the army of the counts of Boulogne, and then retired into the privacy of married life. It was not until 1095, after he had kindled and fostered a fanatical zeal in the solitude of a hermitage, that the real force of his character began to appear. Happening about that time to be on a pilgrimage to the Holy Sepulchre, and feeling enraged at the indignities offered by the Moslems to the scenes of sacred history, he formed the arduous project of wresting Palestine from the infidels. To return to Europe and lay his plan before the Supreme Pontiff was his first measure. The Pope approved of the enterprise, and sent him forth to preach a *crusade*. A bare-headed, bare-footed, little, shrivelled old man, mounted on an ass, wrapped in a coarse garment, girded with a rope, and bearing a heavy crucifix in his hand, Peter the Hermit rode forth to summon Christendom to arms. As he addressed the people that everywhere thronged his path, he rose to the highest fervour of enthusiasm. His lively imagination conjured up the scenes of profanity transacted in the Holy City; his keen eye kindled martial fire among the populace; he burst out at intervals into wrapt ejaculations to heaven; he drowned his voice betimes in a tempest of sighs and tears. How he succeeded in raising the first Crusade, and how he failed in conducting the expedition, is given under Crusades. The subsequent part of the Hermit's career is merged in obscurity. He died in 1115 in a monastery which he had founded in the diocese of Liège. (See Gibbon's *History*.)

Peter *of Blois* (better known under the Latin form of his name, *Petrus Blesensis*), a learned man of the twelfth century, was born about the year 1120, at the city of Blois in France, from which he derived his name. He studied first at the university of Paris, where he displayed a fondness for poetry and rhetoric. From Paris he proceeded to Bologna to study civil and canon law, a branch of knowledge in which he very much excelled. A long-lost work of Petrus Blesensis on canon law and process was discovered some years ago, and an account of it published in the *Zeitschrift für Geschichtliche Rechtwissenschaft*, vol. vii. From his writings it appears that he cultivated medicine, and several branches of the mathematics, with no little care and success. But the study of theology formed the chief delight and business of his life. Unfortunately, however, the theology he studied was of that scholastic kind which consisted in vain attempts to explain and prove by logic the many absurd opinions which then prevailed. In attempting to explain the doctrine of the real presence, as held by the Latin church, he was the first who employed the famous term *transubstantiation*, which was soon afterwards adopted by the church, and has ever since been retained. Being appointed preceptor to William II., King of Sicily, in 1167, he obtained the custody of the privy seal; and, next to the Archbishop of Palermo, who was the prime minister, he had the greatest influence in all affairs. His power, however, was not of long duration; for the archbishop being banished in 1168, Peter soon afterwards left the court of Sicily, and returned into France. But in a short time he found another royal patron, having been invited into England by Henry II., who employed him as his private secretary, made him archdeacon of Bath, and gave him some other benefices. Having spent a few years at court, however, he got tired of that way of life, of which in one of his letters he has drawn a very unpleasing picture, and retired into the family of Richard, Archbishop of Canterbury, who had made him his chancellor about the year 1176. In this station he continued until the death of the archbishop in 1183, enjoying the highest degree of favour with that prelate, though he used much freedom in reproving him for his remissness in the government of the church. He continued in the same station in the family of Archbishop Baldwin, who succeeded Richard, acting both as his secretary and as his chancellor. In 1187 he was also sent by the latter prelate on an embassy to Rome, to plead his cause before Urban III. in the famous controversy between him and the monks of Canterbury respecting the church of Hackington. After the departure of his friend and patron Baldwin for the Holy Land in the year 1190, Peter was in his old age involved in various troubles, the causes of which are not distinctly known; and he died in England in 1200. He appears from his works, which may be justly reckoned amongst the most valuable monuments of the age in which he flourished, to have been a man of great integrity and sincere piety, as well as of a lively, inventive genius, and uncommon erudition. His printed works consist of a great number of letters, which he collected together at the desire of Henry II., and of sermons and tracts. The best edition of his works is that of Pierre de Goussainville, Paris, 1667, fol.

Peter I., Czar of Russia, usually syled "The Great," was born in 1672, succeeded to the undivided sovereignty in 1689, and died in 1725. (See Russia.)

Peter II., Czar of Russia, grandson of the preceding, was born in 1715, ascended the throne in 1727, and died in 1730. (See Russia.)

Peter III., Czar of Russia, another grandson of Peter

[1] Horne's *Introduction*, vol. iv, p. 434, ff.; Sherlock's *Dissertation on the Second Epistle of Peter.*

the Great, was born in 1728, succeeded to the throne in 1762, and was strangled in the same year. (See RUSSIA.)

PETER'S PENCE, the name applied to an annual tribute of one penny formerly paid to the Pope at the festival of St Peter. In England every family possessed of twenty pennyworth of any sort of goods was considered liable. Ina the Saxon king, when he went in pilgrimage to Rome about the year 740, paid this contribution to the Pope, partly as alms and partly in recompense of a house erected in Rome for English pilgrims; and the same continued to be paid generally until the time of Henry VIII., when it was enacted that henceforth no person should pay any pensions, Peter's pence, or other impositions, for the use of the bishop or see of Rome.

PETERBOROUGH, a parliamentary borough of England, the county town of Northamptonshire, stands on the left bank of the Nen, here crossed by a wooden bridge, 40 miles N.E. of Northampton, and 76 N. by W. of London. It consists of several streets, close to the river, straight, well paved, and lined with good houses. To the west a suburb has been erected, which contains many handsome houses. The most important public building is the cathedral, a fine old specimen of Norman and early English architecture. It is in the form of a cross, of the following dimensions,—length, 476 feet; breadth of the nave and aisles, 78 feet; height of the ceiling, 78 feet; breadth at the transepts, 203 feet; breadth of the transepts, 69 feet; height of the central tower, 150 feet. Its most striking feature is the west front, which is an addition to the nave, and consists of three pointed arches 80 feet high, supported by clustered pillars, and surmounted by lofty pediments and pinnacles, while at each end rises a turret with a spire. The interior is beautiful and well proportioned, but contains few monuments or shrines, as it was stripped of most of its ornaments during the civil wars. Katherine of Aragon and Mary, Queen of Scots, were both buried in Peterborough cathedral; but no monuments mark the places; and the remains of the latter were afterwards removed to Westminster Abbey. At the west front of the cathedral is a court, containing various well-preserved remains of ancient monastic edifices. Besides the cathedral, Peterborough contains several handsome public buildings. The parish church is a large stone edifice; the town-hall is small but neat; and the corn exchange, built in 1848, is a handsome specimen of the Italian style, and contains a large market-room lighted from the roof. There is also a jail, and house of correction of Norman architecture. The Dissenting places of worship include Wesleyan, Independent, Baptist, and Primitive Methodist chapels. There is an endowed cathedral grammar school, which had, in 1854, thirty-three scholars; another endowed school, a national school, infant schools, a mechanics' institution with a library, and a savings-bank. The benevolent establishments comprise a dispensary, an infirmary, alms-houses, &c. The trade of Peterborough consists chiefly of corn and malt, brought down the Nen from the interior for export; and of coal, timber, bricks, and stone, which are imported. The principal manufactory is a large steam flour-mill recently erected. Peterborough is the seat of a bishop; and the dean and chapter have a certain jurisdiction over the town, as there is no corporation. Since the time of Edward VI., the borough has returned two members to Parliament. An abbey was founded here by Peada, the son of Penda, King of Mercia, during the time of the Heptarchy. Its original name was *Medeshamstede;* but this was changed to that of *Burgh*, *Gildenburgh*, or *Peter-burgh*, in the time of Edgar, when it was restored, after having been destroyed by the Danes in the ninth century. A village soon began to rise around it; but in 1116 this, as well as a large part of the abbey, was destroyed by fire. The restoration of the monastic buildings was soon commenced, and gradually carried on for a long time; and it was not till the beginning of the sixteenth century that the cathedral assumed its present aspect. At the time of the Reformation, Peterborough was one of the most magnificent of the ecclesiastical establishments, and was chosen by Henry VIII. as the seat of one of the new bishoprics. The monastic buildings were then preserved; but they were destroyed in the time of Charles I., and the cathedral itself much injured. Pop. 8672.

PETERBOROUGH, EARL OF. See MORDAUNT, *Charles.*

PETERHEAD, a parliamentary and municipal burgh and seaport of Scotland, in the county of Aberdeen, stands on a peninsula, forming the most easterly promontory of the mainland, 33 miles N.N.E. of Aberdeen, and 146 from Edinburgh. The streets are for the most part broad; and being exposed to the bracing breezes of the ocean, it is peculiarly exempt from epidemical diseases. It is well supplied with excellent spring water, brought from about 3 miles inland. The houses are built of the fine red granite which is quarried in the vicinity, and which takes its name from the town. Among the public buildings, the most important is the town-house, which has a handsome spire 125 feet high. The parish church, built in 1803, near the west end of the town, is also surmounted by a lofty granite spire of the height of 118 feet There are also places of worship belonging to the Free Church, the Scotch Episcopal Church, the United Presbyterians, Independents, Methodists, and Roman Catholics. The market-cross, erected in 1833, consists of a Tuscan column of granite, having on the top the armorial bearings of the earls marischal, surmounted by the Scottish lion. The principal educational establishments of the town are the parish school, the Free Church school, the academy, the Episcopal Church school, and the union or industrial school; and there are also a news-room and an extensive circulating library. There is a museum and a cabinet of coins of considerable value, the gift of the late Adam Arbuthnot, Esq.; but from want of adequate accommodation, these collections have not yet been rendered properly available. There is a sick benefit institution, and several friendly societies. The manufactures are not extensive; but there are large bone and saw mills, an iron foundry, a woollen cloth manufactory, a rope-work, breweries, and a brick and tile work, besides extensive premises for oil-boiling and the other processes connected with the extensive fisheries which are carried on. Peterhead ranks high as an enterprising commercial and seaport town. Here the Greenland whale and seal fisheries have been carried on since 1788. At present there are 28 vessels employed in that trade, of 7885 registered tons, and manned by 1385 seamen. This number exceeds that of all the vessels in the trade from the other ports in Great Britain. During the nine years from 1849 to 1857 there were brought to Peterhead the produce of 651,474 seals and 207 whales, which, besides the seal-skins, yielded 10,863 tons of oil and 2783 cwt. of whale-bone, and the value is estimated at L.550,398. The herring fishery is also extensively carried on, the number of boats commonly ranging from 230 to 400 annually, ranking in this respect second only to Wick among the stations on the coasts of Scotland. The white fishery is actively carried on at the villages in the neighbourhood, and the fish is brought to Peterhead for shipment to the London and other markets. Besides the exports arising from the fisheries and the agricultural produce of the district, there is a considerable export of granite from the extensive quarries in the vicinity. It may be obtained in very large blocks, and when polished is very beautiful. The pillars in the British Museum, the docks at Sheerness, the York column in London, and many other public works, are of Peterhead granite; and in a polished state it has been used in many ornamental designs. The principal imports consist of British and foreign timber, tar, hemp, coals, lime,

manure, salt, iron, wool, soft goods, groceries, flour, and wooden hoops. Peterhead has a custom-house on the full establishment for the district, which includes Fraserburgh and Boddam. Ship-building is carried on to some extent. The number of sailing-vessels registered as belonging to the port on December 31, 1857, was 74, tonnage 13,419; steam-vessels 2, tonnage 327. During 1857 there entered the port 544 sailing-vessels, tonnage 59,389; and 26 steam-vessels, tonnage 3978; while there cleared 406 sailing-vessels, tonnage 18,827; and 26 steam-vessels, tonnage 3978. Peterhead possesses two harbours, the north and the south, which communicate by means of a canal; and thus vessels may enter and leave the one or the other in any wind. That portion of the peninsula thus formed into an island is called Keith Inch, and is connected with the mainland by an excellent swing-bridge with a double roadway. The south harbour has a depth of 11½ feet of water at medium spring-tides, and the north harbour 16½ feet. They have together an area of about 17 imperial acres, and are protected by substantially-built breakwaters, within which are commodious quays and piers. There are also two excellent graving-docks, where repairs can be speedily made on vessels under 600 tons. The south breakwater was constructed in 1773, according to a plan by the late Mr Smeaton, engineer; and the north breakwater in 1818, according to a plan by the late Mr Telford. About L.105,000 have been expended on the building and improving of these harbours and docks since 1773, of which L.15,000 was obtained from government by grants from the forfeited estates fund. The harbour revenue amounted for the year 1857–8 to L.4392. The importance of the harbours is enhanced by their being situated near the outer extremity of the south bay, a beautiful sheet of water, nearly 2 miles across, and extending more than a mile inland. It has ample depth of water for a fleet of the largest vessels, and its anchorage is of a very superior description. To protect this bay with proper breakwaters is all that is necessary to make it a national harbour of incalculable value. So long ago as the reign of Charles II. the importance of the harbours of Peterhead as a port attracted the attention of the legislature, and an act was passed for their improvement; and since then, from time to time, public attention has been directed to them. At present they are being made the subject of inquiry by a royal commission appointed to report on the best site for a harbour of refuge on the east coast of Scotland. For this purpose, from what has been said, it will be seen that Peterhead offers many advantages. It is also nearly midway between the firths of Forth and Cromarty, it occupies a salient position on the coast, and is the nearest point of Britain to the Baltic. About 240 vessels take shelter annually in these harbours, and about 600 in the south bay, in its present unprotected state, which prevents its being available in the winter months. A railway between Aberdeen, Peterhead, and Fraserburgh is about to be constructed, which will materially contribute to the prosperity of the town. Peterhead was for upwards of two centuries a favourite watering-place, and its mineral waters were in repute for stomach and bowel complaints, nervous affections, and general debility. Sea-bathing is also to be had here, either on the shores of the open sea, or in the baths, of which there are two for the different sexes, with hot-water vapour baths, &c. Peterhead was erected into a burgh of barony by George, earl marischal, in 1593, previously to which it was an unimportant fishing village. A large portion of the lands in the parish continued to belong to the marischal family till 1715, when they were forfeited to the Crown, the then earl having actively espoused the cause of the Stuart family. The estate was then purchased by the York Building Company, who sold it in 1728 to the governors of the Merchant Maiden Hospital of Edinburgh, who still continue to be the superiors of the town. By the original charter in 1593, the earl marischal established a municipal government in the town, and the system continued till the passing of the Burgh Reform Act in 1833, which conferred on the town the privilege of electing a provost, three bailies, and a treasurer, out of a body of twelve councillors appointed by the electors. Peterhead unites with Elgin, Cullen, Banff, Inverury, and Kintore in returning a member to Parliament; and its constituency amounts to 250. The population of the burgh in 1851 amounted to 7747, besides about 500 absent seamen. The rental of property within the burgh amounts to L.14,081. The assessment for poor in the parish in 1858 was L.2200. The remains of two ancient small forts, and the ruins of Ravenscrag, and of the castle of Boddam, are in the vicinity. Ravenscrag is a fine specimen of an old baronial castle, not in a very dilapidated state. The walls are in many places 11 feet in thickness; and the date of its erection is assigned to the eleventh or twelfth century. The ruins of Boddam Castle stand on a narrow promontory immediately south of Buchanness, on each side of which there is a deep chasm, forming precipices of great height. A good many relics of antiquity have at different times been found in the neighbouring parishes.

PETER-LE-PORT, or St Peter Port, the chief town of the island of Guernsey, on a bay on the east coast. It is built on the slope of a hill, and extends nearly a mile along the shore, presenting a very fine appearance from the sea, as the houses rise one above the other along the slope. In the Old Town, the streets are narrow, irregular, and steep, and the houses old and gloomy-looking; but the New Town, as the upper part of St Peter Port is called, and especially Hauteville, which lies to the S.W., are more modern, and much better built; while the neighbouring country is extremely beautiful, and is studded with villas belonging to the gentry, who seldom reside in the town itself. Among the public edifices, one of the most important is the government-house, a large though somewhat heavy building. Near it stands Elizabeth College, founded in 1563 by that queen, and rebuilt (1826–30) in the Tudor style; and not far off is Victoria Tower, erected in honour of the Queen's visit to the town in 1848. St Peter's church, built in 1312, has a tower with a low spire in the centre, and is a good specimen of the flamboyant style of architecture; and there are in the town a number of other churches and chapels belonging to Methodists, Independents, Baptists, Quakers, Roman Catholics, and Plymouth Brethren. The town has also a neat court-house, custom-house, prison, public library, assembly-rooms, and theatre. Besides the college, which has three fellowships and five scholarships at Oxford, there are several schools, as well as a mechanics' institution, with a library of 3000 volumes. The principal charitable establishment is the town hospital for the sick and destitute. The harbour of St Peter Port, formed by two piers 80 feet apart at the entrance, is hardly large enough for the trade of the place. The roadstead, however, affords good anchorage, and is sheltered from the S.W. Two forts, Castle Cornet, an ancient and picturesque structure on a small island within half a mile of the shore, and Fort George, on the heights about half a mile south of the town, form the defences; and the latter is a place of great strength. The articles manufactured in St Peter Port are tobacco, snuff, soap, candles, bricks, ropes, cordage, cider, and spirits. The principal exports are granite, bricks, cement, potatoes, fruit, and vinegar; the imports, grain, fish, and other articles. St Peter Port sends seventy members to the States of Election, and six to the States of Deliberation. Pop. of parish (1851), 16,778.

PETERS, or Peeters, Bonaventura, a Dutch artist, was born at Amsterdam in 1614. He soon attained great excellence as a marine painter. His storm-pieces repre-

Petersburg. senting a ship foundering upon a rock, and sailors clinging to spars amid the raging surf, were executed with great truth and originality. Scarcely less successful were his pictures of a calm sea-shore, with towns and castles on the coast, and of a sluggish river, with boats and barges sailing before a gentle breeze. He might have risen to still greater proficiency had he not died prematurely in 1652. Bonaventura Peters had a younger brother Jan, who imitated him both in style and in the choice of subjects.

PETERSBURG, or more correctly *St Petersburg*, at present the capital of the Russian empire, the residence of the sovereign, and the official centre of the administration, occupies the most northern position of any large place upon the globe, being in 59. 56. N. Lat., and 47. 58. E. Long. It stands about 20 miles above the mouth of the Neva, on a species of alluvial delta formed by the division of the main current into a multitude of smaller branches, and so exceedingly low as to have been originally almost on a level with the surface of the Gulf of Finland. It is only by the artificial elevation of its marshy soil to from 2 to 5 feet above its original level, that it has been effectively drained, and rendered comparatively free from inundations.

The capture, from the Swedes, in 1702, of Noteburg (now Schlusselburg), a fortress situated at the point of exit of the Neva from Lake Ladoga, together with the taking, in the following year, of the fort of Nyenschantz, by making Peter the Great master of the whole course of the river, seem first to have inspired that active prince with the idea of establishing here a strong military post and a commercial port. On the 16th May 1703, he laid, with his own hands, the foundation of the fortress which still exists in the centre of the city, and to which he gave the name of Petersburg. It is, however, highly improbable that the gigantic project of founding here the capital of an extensive empire could have at first possessed his mind; and it was not till the great victory of Poltava, in 1709, had made him master of the whole southern shore of the Gulf of Finland, that he ultimately determined upon the violent and entirely artificial creation of a city which has been well styled "a loophole by which the light of western trade and civilization was to be admitted into the darkness of half-oriental barbarism" in which Russia was then buried. In a letter written by Peter on the field of battle, announcing to Count Apraxin the important victory he had just gained at Poltava, he significantly says:—"The foundation-stone of Petersburg, which has been for some time ready, is this day, with the blessing of God, definitely laid."

The construction of the city once determined on, Peter proceeded to execute his project with a barbaric energy and ardour which no obstacles could check or abate. The workmen first employed were Finns from the neighbouring districts, Swedish prisoners of war, and criminals condemned to hard labour; but in the end of the year 1709 orders were given to assemble from all parts of the empire, and even from Siberia, skilled workmen and labourers, in two divisions, each consisting of 20,000 men, which relieved each other in spring and summer. Exclusive of these, a large body of masons and bricklayers was separately organized for the purpose, and a forced levy was imposed upon the whole district in the vicinity of Moscow, of 3000 men with axes, of whom every tenth man was to be supplied with carpenter's tools and a horse. This levy amounted to 1 person on every 35 families; and the remaining 34 houses were obliged to give a money contribution, amounting to 2 *altūins* (equivalent to 15d. of our money), in lieu of personal service. During the first four years, it is calculated that 150,000 men were sent to the works at St Petersburg; and in order still further to accelerate its construction, Peter forbade, under the severest penalties, the erection of any brick or stone buildings throughout the empire. By means of this species of impressment, which continued uninterruptedly for nine years, the works rapidly advanced; but at a terrible cost of human life, caused by the unhealthy climate and the nature of the labour. At length it was found expedient to change the system of obtaining labour; and in 1718 the works were distributed among private contractors, and the compulsory impressment was replaced by a pecuniary impost.

Nor were less severe and arbitrary measures employed for peopling the infant capital. The first inhabitants of the city consisted of the labourers collected from the interior of the empire, whose number, in 1713, amounted to 2500 persons, not including 1100 immediately attached to the imperial residences. No voluntary settlers making their appearance, Peter decreed—1. That all persons under age, of noble condition, who were not receiving a public education or attached to the public service, should be obliged to reside in St Petersburg. 2. That all persons attached to the court, and other nobles proprietors of 30 serfs and upwards, should likewise be obliged to immigrate to the new city, and should erect houses there. 3. That a colony of 300 persons from the mercantile community of Moscow, and 300 artificers from the same city, should be transplanted to Petersburg, and 4. In 1717 orders were given to the provincial municipalities, under pain of the severest punishments, to select from the mercantile and artizan classes a certain number of respectable and wealthy families, and to transfer them without delay to St Petersburg. These severe and violent expedients, however, were not always successful in attaining their object: the nobility, under various pretexts, evaded an order which forced them to inhabit a region buried in dreary forests and pestilential marshes; and the settlers from the inferior classes profited by every opportunity to escape. But no obstacles could arrest the indomitable will of Peter: his severe regulations still continued to be enforced, though occasionally with some relaxation (thus, for example, in 1719 the nobles were permitted to absent themselves from St Petersburg, and to visit their estates, but only for five months at a time), and it was not until 1721 that the public offices and state tribunals were transferred from Moscow to the new capital.

The construction of Petersburg began with that portion of the present city which lies in the immediate vicinity of the fortress, on the northern or right bank of the Neva The founder's intention was to cover the Vassílievskii Island with streets and houses, to surround it with defences, and to intersect the whole with numerous canals, like Amsterdam and other towns, which he had doubtless admired, in Holland This project, however, was not executed. During the reign of Peter some portions of the Admiralty quarter (on the southern bank) began to be built upon; and it is to this period that we must ascribe the erection of the following important edifices, some of which either no longer exist, or have been transformed to other purposes:—The four palaces (the Summer Palace, the Winter one, that of the Tsarévitch Alexéi, and that of the Tsarévna Natália), the cannon foundry with its village of habitations for the workmen, the admiralty, the galley-wharf, the Gostíinnui Dvor or bazaar, and several residences of high functionaries. Some of the measures adopted by Peter to make his new capital the principal seat of foreign trade with the countries lying on or beyond the Baltic were as arbitrary as those by which he built and peopled the city; for example, in 1717 the port of Archangel was forbidden to export more than one-third of the whole amount of its goods, while the remaining two-thirds were to be sent to Petersburg. In consequence of these protective measures, the foreign trade of the new city soon began to exhibit a rapid development; so much so, that in the last years of Peter's reign the number of foreign vessels that entered at Cronstadt (which was founded at the same time with Petersburg, and of which it forms the port) had risen to 120, or at least one-tenth of the amount at the present day.

The death of Peter the Great was followed by the abandonment or the neglect of those energetic measures which were indispensable for the prosecution of a task so artificial as the construction of a capital in an unfavourable site; and the inhabitants, under various pretexts, left unfinished the erections they had begun. To complete the disorganization, a number of fires occurred in 1736 and 1737, unquestionably the work of incendiaries, whose obstinacy could scarcely be overcome by the severest punishments. Many spots thus became unoccupied, and multitudes of families remained without a shelter, the devastated ground being allotted, without regard to the rights of the former occupants, only to such persons as would undertake to build without delay. To put a stop to these irregularities, the Empress Anna Joánnovna ordered the formation of a committee, of which Münich was president, charged with superintending the rebuilding and extension of the city. In general, it may be said that the town began to improve again during this reign: it was divided into five wards; and about 1737 it numbered more than twenty churches and 70,000 inhabitants.

Under the Empress Elizabeth Petróvna, the violent measures employed to secure the peopling of Petersburg began gradually to be modified and relaxed. The inhabitants acquired the right of purchasing and selling houses, and all classes now exhibited a gradually increasing willingness to settle in the new capital. Towards the end of this reign the population reached 150,000. Among the skilful architects invited from foreign countries to contribute to the adornment of the city was the famous Rastrelli, who constructed the Winter and Anitchkoff palaces, the beautiful church of the Smolnoi monastery, and the houses belonging to Count Strógonoff, to Voronzóff (now the Page-Corps), Razumóffskii, and Bóbrinskii (at present the Foundling Hospital). To this reign also belongs the erection of the cathedral of St Nicholas of the Sea, the church of the Annunciation in the Haymarket, the brick bazaar, or Góstinnoi Dvor, and many other edifices which still adorn the city.

The Empress Catherine II. exhibited an enlightened policy in

abolishing all the oppressive regulations which had been intended to promote the development of St Petersburg, and succeeded in attracting thither considerable numbers of the middle and industrious classes, by the advantages and privileges she accorded to such as were willing to settle there; so that towards the end of her reign the population had reached 220,000, and the town was divided into ten wards, containing 4600 houses, one-fifth of which belonged to the state. Among the remarkable edifices of this epoch we may specify the cathedral of the Alexander-Névskii monastery, the Marble and Tauride palaces, the Hermitage, and the Academy of Arts.

During the short reign of Paul considerable attention was given to the more equable allotment of the municipal imposts, and to the relief of the inhabitants from the billeting of troops: for the latter object several barracks were constructed; and the reforms begun in this reign were carried out by the emperor's successor, Alexander I. Few important additions were made to the architectural beauty of the city,—the most considerable being the castle or palace of St Michael, then strongly fortified, and surrounded by a fosse. It is to the reign of Alexander I. that Petersburg owes the regularity of its appearance, as well as a number of its most ornamental edifices; among which we may particularize the cathedral of Kazán, the Preobrajènskii church, the palace of the late Grand Duke Michael, the vast *Etat-Major*, the Great Theatre, the Exchange, and others. Towards the end of this reign the city contained 7600 houses and 400,000 inhabitants.

During the administration of the late Emperor Nicholas many new edifices and monuments were added to those already existing; as the cathedral of the Holy Trinity, the Senate, the cathedral of St Isaac, the custom-house, two theatres, the offices of the departments of the interior and public instruction, the Technological Institute, a number of vast barracks, the Alexander column, &c. At the commencement of the present reign Petersburg may be regarded as covering a space of more than 80 square versts (26 square miles), as containing 8230 houses and 480,000 inhabitants.

The river flows through a space of about eight miles within the city, and divides, at nearly the centre of this part of its course, into three principal branches,—the Great Nevà, the Little Nevà, and the Névka, separating the town into four districts or "sides;" that of the Admiralty (lying on the left bank), that of the Vassílievskii Island (in Russian, *Ostroff*), that of Petersburg, and that of Viuborg. The width of the Great Nevà varies extremely in different parts of the city: at its broadest point, a little above the fortress, where it is crossed by the Tróitskii (Trinity) Bridge, it is 2100 feet from bank to bank; while at other points it varies from that to about 1000 feet. The banks of the principal arm, during its passage through a great portion of the city, are on both sides lined with most magnificent granite quays, of a truly Roman grandeur and solidity of construction. The latter being furnished with an almost uninterrupted *trottoir* for foot-passengers, and broad roads for carriages, give to the city that monumental character of regularity and splendour which renders this capital in some respects the most imposing in Europe. The intensely blue colour and purity of the waters of the Nevà, and the rapidity of the current, give to this beautiful river the appearance of being always full, and render it a main ornament to the capital. The rapidity of the current is indicated by the number of cubic feet of water flowing in one second at the following places:—Above the Nevskii monastery, 114,659½; below the Okhta, 115,103¼; at the Summer Garden, 89,932⅔; opposite Baird's foundry, 73,983½. The depth of the stream is also extremely unequal; being greatest within the limits of the city, generally diminishing after the principal stream divides into branches, and below the town having its bed so encumbered with sand-banks as to leave but a very narrow and winding channel for allowing vessels—and only those of very moderate burthen—to come up to Petersburg, where are situated the custom-house establishments. All large ships are thus obliged to discharge at Cronstadt, where they remain, while their cargoes are carried up and down the Nevà by lighters. The expense and inconvenience of this trans-shipment is great; and the delay so considerable, that a cargo is often longer in its transit from Cronstadt to Petersburg than in its voyage from London to Cronstadt in a sailing-vessel. Steam-tugs have only been for a comparatively recent period employed on the river. Men-of-war, all vessels of large size, built at Petersburg, have to be transported, even when empty, by means of "camels," over the shallows which obstruct the navigation below the city. The water of this river is unusually pure, light, and transparent, and is found to be very wholesome; but when used by strangers for the first time it not unfrequently produces a slight derangement of the digestive organs. A chemical analysis of the water, made by Hess, established the fact of its remarkable purity, 109 lb. giving only 47·2 grains of foreign ingredients.

Petersburg being far above any tidal influence, the destructive inundations which from time to time have occurred arise from the direction and long continuance of violent winds, combined in some cases with the melting of the ice in Lake Ladoga. Strong southerly gales, afterwards veering to the S.W. and W., by driving a large body of water up the gradually-narrowing bed of the Gulf of Finland, have on many occasions raised the level of the water in the Nevà 7, 9, 10, or more feet, causing it to overflow its banks, and spread devastation and ruin over the low-lying quarters of the city. Since the foundation of Petersburg, thirty-five considerable inundations have been recorded, the most violent and disastrous having taken place on the 10th September 1777, and 7th November 1824. On the former of these dates the water rose to 10½ feet, and on the latter to 14 feet above its ordinary level. The western quarters, or those lying nearest the sea, suffer most from these calamities; those quarters which lie farthest from the sea having never been at all damaged. It is probable that these inundations will become gradually less and less frequent, partly from the silting up of the mouths of the river, and also partly from the upheaval which the bed of the eastern portions of the Baltic is gradually undergoing.

The Nevà, from the rapidity of its current, would probably never be frozen over but for the immense quantity of ice floated down from the Ladoga, which, after covering the river for a longer or shorter time in drifting masses, is ultimately frozen into a solid mass, sometimes attaining, in prolonged seasons of severe frost, a thickness of 3 or more feet, and supplying the inhabitants with excellent sledge-roads, as well as a large course for trotting matches, which is annually erected in view of the Winter Palace. The surface, however, is usually at first very uneven, presenting huge blocks of ice of the most irregular and fantastic shapes; and it is not till all the inequalities are levelled by a thick coating of snow, that a sledge, much less a skater, can make its way among its jagged edges.

The period at which the Nevà is definitively frozen over varies from the latter half of October to the first half of December: in general, however, it is covered with ice about the middle of November. The ice remains without breaking up in general to about the middle of April, though there have been years when the opening of the river occurred as early as the 20th of March, and as late as the end of April, O.S. (*i.e.*, the 12th of May). The mean duration of the time during which the river remains covered may be said to be 146 days. There have been years—as 1816—when the river, after the breaking up of the ice, has been again frozen over; but such events are rare. About a week or a fortnight after the breaking up of the ice upon the river itself, large masses of that which covered the lake begin to come down; and this lasts for a considerable time. The processes of freezing and of breaking up of the ice are of longer or shorter duration according to the state of the weather; and while the ice is passing, the bridges of boats being necessarily removed, the only communication with the opposite shore was formerly by means of small boats somewhat resembling the caiques of the Bosphorus. Occasionally even this mode of transit was rendered impossible by

Petersburg. the density of the floating stream ice, and then all communication whatever was interrupted for hours, and even in some instances for a whole day. The completion, however, of the handsome new bridge—of cast-iron, resting upon granite piers—projected and terminated in the reign of the late emperor, has in some measure remedied this inconvenience; but Petersburg is still very deficient in bridge accommodation of a permanent character.

Independently of the arms or branches into which the Nevà divides, the city is intersected by a number of canals. Of these, the most considerable is the Fontânka, which has a general depth of 11 feet, and a breadth of about 180 feet, admitting a multitude of the rude and cumbrous barges or "barks" which bring firewood, hay, grain, &c., from the interior of the country. Watermen also ply for hire upon these canals; and at short intervals large roofed and windowed barges are permanently moored, serving as floating shops for the sale of fish, which are kept alive in boats alongside sunk almost under water, and thus can be supplied even in the severest winters. Besides the Fontânka, five other canals might be mentioned, but they are all much inferior to it both in depth of water and in breadth. They for the most part follow a more or less curved direction, communicating at both extremities with the Nevà; and thus all possess some degree of current, though generally of a force insufficient to secure them from silting up, unless periodically deepened by artificial means. They unquestionably add much both to the beauty and the salubrity of the town, though they are hardly rapid enough for perfect drainage; and in the intense heats of a Petersburg summer the effluvia from them are sometimes disagreeable. They are crossed by about 170 bridges, generally of stone piers with a drawbridge, to allow the passage of vessels; but as masted craft now never enter them, the latter arrangement is rapidly giving way to the use of iron, and several of them are on the suspension principle. The number of these canals, which in traversing the city in any direction the traveller is perpetually crossing, gives to St Petersburg an appearance quite original and characteristic, unlike that of Venice, and no less dissimilar to that of the great cities of Holland, but still very striking and remarkable. The great feature of the canals is the interminable lines of majestic granite quays with which these avenues are everywhere lined and bordered, in nothing inferior to the noble structures of the same kind with which the Nevà is bound in during so large a portion of its course within the city. The water in the canals, from the sluggishness of the current, and the great amount of sewerage delivered into it from the houses, is of no very inviting purity. All the drinking-water of the inhabitants is supplied from the river, and is taken through the town in barrels placed upon wheels and drawn by horses. The employment of the steam-engine and high-pressure service-pipes has not yet been generally adopted.

For purposes of police and administration, Petersburg is divided into thirteen quarters (*tchast*) as follows:—The four Admiralty quarters, Litêinaia (Foundry), Moscow, Narva, Karétnaia (Carriage), Rojéstvenskaia, Vassílevskii Island, Petersburg, Wyborg, and Okhta. Each of these is subdivided into from three to six wards (*kvartál*), with the exception of the last, which has only two.

Of these it may be remarked that, generally speaking, the four Admiralty quarters, and that of the Litéinaia, all lying on the southern or left bank of the Nevà, are more particularly inhabited by the richer and fashionable classes, and by the higher order of government officials, and are the seat of the principal public buildings and most imposing monuments; while the Vassílievskii (Ostroff) is the chief centre of commerce and of learning (containing the exchange, the custom-house, the academies of arts and sciences, and the university); and the Petersburg, and still more the Wyborg quarters, must be looked upon as the poorest and most remote districts. The various branches of the Nevà form a considerable number of islands, some of which are covered with country houses and gardens, the summer residences of the higher classes. The principal of these are the islands of Yelâghin (where there is a summer palace of the emperor), Kâmennii, Krestóvskii, Petróvskii, and Aptékarskii, or Apothecary Island, so called from the botanic garden which has been established on it. Most of these are laid out in a park-like manner; and in summer, when their numerous fantastic villas are inhabited, they present an animated and beautiful appearance.

The general disposition of the streets in the Admiralty district of St Petersburg is monotonously symmetrical. The central point is the enormous square, or "place" (for it is far from being a square), of St Isaac, on which stand the Winter Palace, the Admiralty, the Senate, the cathedral of St Isaac, and other important monuments and public buildings. From this square, diverging like radii of a circle, the centre of which is the chief entrance of the Admiralty, crowned with a lofty gilded spire, visible from every point of the city, run three great principal streets or *prospekts*, forming a small angle with each other, and extending, in perfectly straight lines, to a great distance. Of these, the widest and handsomest in the town is the famous Névskii Prospect, not much less than 3 miles in length from its origin to its termination at the monastery of St Alexander Nevskii; the next is the Gorókhovaia (Pease Street); and the third the Voznessénskaia (Street of the Ascension), each about half the length of the Nevskii, and large and busy thoroughfares, though inferior to the first both in width and in the number and splendour of the houses which line them. These three main avenues are themselves traversed, nearly at right angles, by a number of transverse streets, among the principal of which are the Great Morskâia, the Great Garden Street (Sadóvia), the Vladimirskaia, and others. All the streets, with the exception of a few in the remoter and poorer quarters, are paved with small stones; but some of the principal ones are laid down with wooden hexagon blocks, as was tried some years back in London; and provided with flagged footways. The latter are in the Nevskii of ample, and even almost superfluous width; but in the more busy and less fashionable quarters they are much cramped by frequent openings to steps leading downwards to cellars and underground shops.

The Vassílievskii Ostroff, the next important quarter of the town, is laid out with mathematical and almost fatiguing regularity. Running parallel with the Nevà, and with each other at equal distances, are three prospects, the Great, Middle, and Little, and these are intersected at exactly equal distances, and at right angles, by a great number of streets called lines, known by their successive numbers up to nearly thirty. The word "line," as here used, indicates not the whole street, but only the row of houses forming one side of it; so that each street consists of two "lines." The roadway of all the streets, instead of, as in England, forming a rounded surface, which is highest in the middle, slopes downward from each side towards the centre, which being the lowest part, forms a channel along which the rain or melted snow is directed. The streets of the city present in general a showy, and even grand appearance; the great height and immense size of the houses, and the uniformity of their appearance,—the police regulations obliging each proprietor to employ stucco or whitewash in which only a moderate selection of tints is permitted,—all contribute to confirm the appropriateness of the title of "City of Palaces" which travellers have given to St Petersburg. But after a short residence, the impression of magnificence which this capital at first excites gives way to an overpowering feeling of monotony and artificial, or rather *mili-*

 tary formality and stiffness; and the "City of Palaces" seems gradually to have transformed itself into a city of barracks. The eye and the imagination seek in vain for that stamp of individuality, that atmosphere of national character, which gives a kind of mingled strangeness and homeliness to cities much inferior to St Petersburg in architectural pretension, and which forms, so to speak, the *physiognomy* of a place. Here all seems obtrusively to assert that the whole was a creation of yesterday, the effort of single will; and the stranger cannot refrain from feeling that, as a mighty individual breath called up from the swamps of Ingria this wondrous exhalation of artificial magnificence, it might again pass into nothingness without occasioning any void among the nations of Europe. The total number of streets in Petersburg is rather above 450. They are tolerably well lighted—the principal thoroughfares with gas, the others with lamps. For the protection of the city and the preservation of order, Petersburg is under the charge of a military and civil governor, and of a grand master of police, who has under him the chiefs of the quarters (*tchástnii prístav*), and their subordinates the ward-officers (*kvartálnii*), each of whom has a certain fixed extent of jurisdiction. In each quarter there is an office for the transaction of police business, having among others a bureau for the registration of passports, &c., a tribunal, a lock-up house for criminals and disorderly persons, and a station for firemen, who are all soldiers; and indeed the whole of the police are organized in military fashion, the officials wearing the military uniform and enjoying military rank. The police-station of every quarter is furnished with a lofty tower, in which a sentinel is continually on the look-out for the first indications of a fire. Signals are immediately given by a certain number of black balls by day, or lanterns by night, hoisted on an iron frame, which crowns the look-out tower; and the point where the fire has occurred being instantly communicated to all the stations, a large number of men and engines are speedily on the spot. By one of the curious half-oriental customs which abound in this country, the emperor, when in Petersburg, or at all events some member of the imperial family, is almost invariably present at any fire that breaks out. The corps of firemen consists of about 950 persons, with 52 engines, to which, in case of need, could be added a large number of men and engines belonging to the regiments of the guard. At frequent intervals, generally at the corners of the streets, are erected small wooden watch-houses, called "búdkas," at the door of which stands a sentinel, till lately armed with a species of halberd or battle-axe. Of these erections there are altogether 310 in the city, to each of which are attached three watchmen, who relieve each other in mounting guard day and night. In spite of the number of its functionaries and the elaborateness of its organization, the police of St Petersburg is one of the worst and most inefficient in Europe; and the rarity of any important disturbance of public tranquillity is to be attributed rather to the extreme docility of the national character, than to the ability or intelligence of the police. The salaries allotted by government being in most cases ludicrously inadequate either to the securing of personal integrity, or even to enable the various functionaries to maintain the style of living which it is nevertheless expected they will keep up, have rendered the Russian police notorious for corruption and dishonesty, and the bad reputation of the body—bad even in a country where the plague-spot of official peculation is so widely spread—has tended to exclude from its ranks not only men of comparatively respectable position and education, but even all such as set much store by the good opinion of society in general.

Petersburg is remarkable not only for the width and regularity of its streets, but for the number and occasionally the enormous extent of its squares, a few of which have a central inclosure planted with trees, as in London, but the greater number corresponds rather to the French "place," being properly squares neither in regularity of form nor in possessing the ornament of gardens. Many of them are so vast and empty as to destroy all impression of grandeur by leaving no proportion between the height of the buildings that surround them and the huge desert of their expanse. The largest and most imposing of them all is the enormous irregular space made up of the different squares respectively styled those of the Winter Palace, bounded by that edifice, the Etat-Major, and extending along one end of the palace to the river; of the Admiralty, giving off the Nevskii Prospect and the Gorokhováia opposite the centre of the last-named building; of St Isaac; and of the Senate. Vast and striking as are the numerous edifices which line various parts of this great inclosure, they fail to produce their full effect upon the eye, and they appear insignificant in comparison with the extensive desert amid which they rise. Of the other squares, the most important are the Sennáia, or Haymarket, which is the largest and best-frequented mart for provisions, and where the frozen animals, skinned and preserved whole, form in winter a spectacle so new and curious to the stranger in Russia. The Champ de Mars, as it is generally called, though its proper name is Tsarítzin Lug, is a vast and very beautiful inclosure for the parading of troops, and is rendered more attractive to the eye by being bounded on two sides by the lofty trees of the summer garden, and the grounds of the palace of the late Grand Duke Michael. What adds to the beauty of this parade-ground is its being close to the Marble Palace, the Place of Suvoroff (where is a bronze statue of that distinguished general), the handsome barracks of the Pávlovskii regiment, and the castle of St Michael. The two squares which most accurately correspond to the idea conveyed to an Englishman by that term are those in front of the Alexandra Theatre, and of the principal façade of the Michael palace. We may also mention the Rumiántzoff square on the Vassílievskii Ostroff, adorned by an obelisk dedicated to the memory of that marshal; the square in which stand the great theatre and the new circus (a very graceful and ingeniously-planned building); and the numerous extensive parade-grounds in different parts of the town, generally in the immediate vicinity of the barracks of those regiments for whose use they are designed. Among these, the most important are the exercising-grounds of the Preobrajênskii regiment (470 by 350 yards), of the Semeónovskii (700 by 470 yards), and of the Izmáilovskii regiment, of dimensions hardly inferior. The Champ de Mars, of which we have already noticed the position, is a rectangle of 525 yards in length by 290 in width; and here take place, particularly on the 1st May, those great parades of the guard in which as many as 60,000 troops, of all arms, are sometimes assembled in one evolution. At the barrier on the Narva and Moscow roads are erected very imposing triumphal arches, the former to commemorate the exploits of the Russian guard during its campaigns against the French, and the second in celebration of the services of the Russian troops in Persia, Turkey, and in the pacification of Poland during the reign of the late emperor.

The general proportion of brick to wooden dwellings in St Petersburg is as 3 to 5; but this ratio varies exceedingly in the different quarters,—in the wealthier being as high as 4 to 3, while in one of the poorer and more remote districts there is only one brick house to 23 wooden dwellings. Generally, also, the size of the houses, and consequently the average number of inhabitants to a house, increases in a direct ratio to the opulence of the particular quarter we may be examining: thus the highest average number of dwellers under one roof is found in the three first Admiralty quarters, the most fashionable portion of the city, where the ratio varies from 115 to 150, and

even as high as 200 individuals to a single house. Many of these residences are therefore of very great extent; and they are generally built round one or even several court-yards, with a carriage-entrance, or *porte-cochère*, from the street, and a multitude of staircases, similar to the arrangement of the inns of court in London, leading to the various apartments. It is consequently very rare to find a single family occupying a whole house; and it is only a few great aristocratic families of unusual wealth whose means enable them to monopolize an entire dwelling. By far the greater number of persons in the upper and richer classes of society rent lodgings or "apartments," as they are called by the French, of a style and extent commensurate with their means. These are generally all on one floor, or "flat;" and the rooms being generally *en filade*, are at once showy on ceremonial occasions and sufficiently convenient in ordinary life. The kitchen and other offices are for the most part on the same floor. Stables and coach-houses are in most cases constructed in the lower storey of the house, opening on the interior court-yard. Shops are common enough even in the largest and most splendid houses; and it is only in comparatively few instances that the proprietor refuses to allow a shop to be established even in a dwelling which has in other respects almost the aspect of a palace. The rooms are almost universally heated by large stoves of white earthenware tiles, or cast-iron painted to imitate marble. The fuel is wood; though an increasing taste for the use of the English grate, and the gradually-growing adoption of coal, together with the increasing dearness of firewood, seems to indicate that in course of time the latter combustible will come into general use. Russia possesses extensive deposits of coal; but the great expense of transport renders it much cheaper to purchase English coal, which is generally imported by ships coming out in ballast.

The number of churches in St Petersburg is 196; of which the Russian-Greek faith has 54 parish churches, 118 domestic chapels, and 2 monasteries. There are also 15 Lutheran places of worship, 6 Roman Catholic, and 1 Arminian. The British factory in Petersburg maintains a handsome and well-frequented chapel of the Church of England; and there is a small congregation of Dissenters connected with the United States mission.

The Russian churches in general never fail powerfully to attract the attention of the stranger by their striking though barbarous architecture, the style being mostly an attempt to reconcile the corrupt Byzantine forms with the details of more classical models. They have uniformly an assemblage of five domes or cupolas—a large one in the centre, surrounded by four smaller ones; these portions of the edifice being in most cases gilded, and glittering in the sun. The tall and not ungraceful campanile, or bell-tower, is usually, as in Italy, detached altogether from the main body of the edifice. The most curious and interesting of the religious edifices of St Petersburg is the monastery of St Alexander Nevskii, considered the third in rank among the numerous *lauras* of the Russian empire. Its superior is the metropolitan or archbishop of St Petersburg and Novgorod, one of the three highest prelates, the other two presiding over the dioceses of Moscow and Kieff. It is dedicated to the saint whose name it bears, and whose relics are deposited in a rich shrine of silver. Here are interred many members of the imperial house, as well as several persons illustrious for their genius or services; as Suvóroff, the historian Karamzín, and the poets Kruilóff and Zukóvskii. The buildings are of great extent; and the conventual precinct, surrounded by a wall, contains a cathedral and five other churches, the residence of the metropolitan, and the cells of the monks, together with the theological academy, a seminary, and the consistory. Divine service is performed here with great magnificence, and the choir (whose voices in the Russian churches are not assisted by any instrumental accompaniment) is celebrated for its perfection.

The cathedral of St Peter and St Paul, in the fortress, on an island on the north side of the Nevà, is surmounted by a slender gilt spire 360 feet in height, which forms a conspicuous object visible from almost every point in and near the city. In it may be seen the tombs of the more recent sovereigns of Russia, together with many trophies won by Russian valour,—as the keys of Warsaw delivered to Suvóroff in 1794, and the colours of the Capudan pasha's flag-ship, taken in 1770, and deposited by Catherine II. with her own hand at the foot of the tomb of Peter the Great. Not far from the fortress, on the banks of the Nevà, is carefully preserved the small one-storied wooden cottage inhabited by Peter the Great, in which may be seen his boat, turning-lathe, many articles of dress worn by him, and a multitude of objects exhibiting his remarkable skill as a turner, joiner, and carpenter. Near this is the curious little wooden church of the Trinity, first constructed by Peter in 1703, in memory of the foundation of the city.

The cathedral of Our Lady of Kazán was erected in memory of the defeat of Napoleon in 1812. It stands on the Nevskii Perspective, and is a clumsy and ungraceful imitation of St Peter's at Rome, consisting of a central building approached in front by a simicircular colonnade, before the extremities of which stand bronze colossal statues of Barclay de Tolly and Kutúzoff. The interior is of great magnificence, the *ikonastás* or screen in front of the high altar being composed of silver (4000 lb. weight) recovered by the Don Kazaks from the French troops, who had plundered it in 1812 from the various churches of Moscow. But the most precious ornament of this cathedral, in the opinion of the superstitious Russian, is the so-called miralous image (picture) of the holy virgin of Kazán. The walls are hung with trophies and colours taken from the French in the course of that important campaign, and with the keys of fortresses occupied by the Russian troops in the years 1812, 1813, and 1814. Among these reposes also the dust of Kutúzoff, who so powerfully contributed to the triumphs of that great national struggle. But the largest and most splendid of the sacred edifices is unquestionably the cathedral of St Isaac of Dalmatia, begun in 1818, and consecrated with great ceremony May 30, 1858. It stands on the Admiralty Square, and is, like all churches of the Greek denomination, in the form of an equal-limbed cross, the centre surmounted by a dome round which four smaller cupolas are disposed at the angles. It is built of granite, highly polished, and the four faces are furnished with as many porticos resting upon gigantic columns of the same stone, the shaft of each being in a single piece. The pediments and the drum of the great dome are richly adorned with bas-reliefs in bronze, colossal statues of angels, &c. &c. This edifice is among the very largest cathedrals of Europe; and its height to the summit of the cross is 317 feet. Nor is it less remarkable for solidity of construction, high finish, and beauty of materials, than for its colossal dimensions or richness of decoration. It is, however, to be regretted that the general appearance is heavy and ungraceful; the different masses are ponderous without dignity, and vast without grandeur; and it is perhaps only the splendid effect of the gilding of the dome and surrounding cupolas that saves the general aspect from being sombre and unmeaning. Nothing can exceed the magnificence of the interior. Enormous columns, entirely incrusted with the most costly malachite, gold, silver, and precious stones, are employed everywhere with the most dazzling prodigality. Many distinguished artists, both Russian and foreign, as Neff and Bruni, have executed frescoes of great size, with which the interior of the dome is profusely decorated; and the general impression of the work—though of course not

to be compared for architectural grandeur either to St Peter's at Rome or St Paul's in London—is unquestionably one of overwhelming magnificence. The construction of this vast and costly edifice was entrusted to a French architect, M. Montferrant, who was fortunate enough to survive to witness the consecration of the cathedral in 1858, but who died a few days after the ceremony. Among the other ecclesiastical edifices may be mentioned the beautiful church of the convent of Smolnoi, constructed by the celebrated Rastrelli; the church of St Nicholas Morskói, both remarkable for their graceful proportions; and the church of the Izmäiloff regiment, deserving of notice for its vast dimensions.

St Petersburg, a city of comparatively recent existence, cannot be expected to possess a very great number of monuments, but those that do exist will stand comparison with the most majestic objects of which any modern capital can boast. The chief are the colossal equestrian bronze statue of Peter the Great erected by Catherine II., and the granite monolithic column raised in memory of Alexander I. Both these monuments stand, in admirable sites, on the Isaac Place,—the former in front of the new cathedral, and between the façade of the Senate-House and the western wing of the Admiralty; and the latter on the space between the front of the Winter Palace and the semicircle formed by the immense building of the Etat Major. The statue is of colossal dimensions, representing the creator of Petersburg in the act of curbing his rearing steed on the very summit of an enormous block of granite which serves as a pedestal, and stretching out his right hand with gesture indicative of sovereign power. The hind legs of the horse are trampling upon a serpent,—the emblem of the ignorance and barbarism over which the hero triumphed in his great work of regenerating an empire; and the reptile, together with the flowing tail of the quadruped, are most ingeniously contrived to add to the equilibrium and stability of the group. The pedestal is a real boulder, brought with immense difficulty from Finland, and on which the emperor is related to have actually stood during his life; and if the stone had been left entirely in its natural state, the work, whether for sublimity or originality, would have left nothing to be desired. Unfortunately, however, it was thought necessary to dress and cut away a considerable portion of the front of the block, so as to give more abruptness to the supposed precipice; but the effect has been to deteriorate very much the grand simplicity of the whole. The inscription consists merely of the following words in Latin on one side of the pedestal, and in Russian on the other:—PETRO : PRIMO : CATHARINA : SECVNDA.

The Alexander column is, we believe, the largest monolithic shaft in the world; it is, altogether, with the bronze pedestal on which it stands, 155 feet in height, of dark granite brought from Finland, and the capital is surmounted by a bronze figure of an angel supporting and pointing to a cross. The latter portion is of no great beauty or significance, nor indeed are the bas-reliefs which ornament the base; but the effect of the simple shaft of stone, unbroken by fluting or any other decoration, is majestic in the highest degree. The diameter of the shaft at the base is 14 feet, and the length of the shaft or monolith itself, 84 feet.

Of the numerous palaces in Petersburg, occupied by various members of the imperial family, the most extensive and splendid is indubitably the Winter Palace, which, with the Hermitage, to which it is united by a bridge over a canal and a series of galleries, forms an uninterrupted line of buildings extending along the Nevà for a distance of above a third of an English mile. The Winter Palace is the actual residence of the emperor, and the present edifice was entirely rebuilt after a fire which destroyed the former building on the same spot in 1838. The general style of the architecture is Italian, and three sides being situated on large open spaces,—the river and its quay, the parade-ground, and the great square on which the Alexander column stands,—presents an imposing effect from many points. The principal apartments are of great magnificence; the hall of St George, the famous "Salle Blanche," the hall of the marshals, the Great chapel, &c., are of noble proportions; the former, at least, adorned with numerous pictures, representing the triumphs of Russian arms by sea and land, and portraits of the sovereigns and illustrious warriors of the empire. Here, too, the stranger is struck by the modest little cabinet in which the Emperor Nicholas passed the working hours of his indefatigable life, the simple and scanty furniture, and the plain iron camp-bed on which he slept and on which he died, covered by the gray military cloak that he always wore. But by far the most interesting portion of the palace is the Hermitage, originally erected by Catherine II. as a place of retreat from the wearisome ceremonial of royalty. This building, to which considerable additions were made by the late emperor, is now transformed into one of the most magnificent museums of art in Europe; and the new buildings, by the skilful manner in which they are lighted, and the indescribable splendour of their fittings-up,—the floors being of the richest parquet-work, and the ceilings (of iron to diminish the danger of fire) most magnificently painted and gilded, form a casket in every way worthy of the treasures they contain. The paintings are arranged in schools; and the gallery is eminently rich in various departments of art. The old pre-Raphaelite painters are well-represented; there are capital works, in the finest condition, of Salvator Rosa, and indeed of all the great Italian masters, with the exception of Raphael himself, and a multitude of works equally valuable for their intrinsic merit and for the light they throw on the history of art. The Spanish subdivision abounds also in *chefs-d'œuvre:* the famous "Christ with the Lamb," and the equally famous "Ascension of the Virgin" of Murillo, together with many interesting though less splendid works of that great painter; a number of most admirable examples of Velasquez, among which may be noticed the two incomparable full-length portraits of Philip II. and Olivarez, together with the finished studies of the heads of the same works, and a crowd of other productions of high interest. Many of these pictures were obtained from the Soult collection. Vandyck is also richly represented, as a very large portion of the Houghton gallery was purchased by the court of Russia. The German, Dutch, and Flemish schools may be studied here with extraordinary success; the collection of Rembrandt alone filling one large hall almost entirely; while the finest works of Teniers, Douw, Wouvermans, Van Ostade, Paul Potter, Terburg, Mieris, not to mention the great landscape-painters—as Berghem, and above all, Ruysdael—cover the walls with a truly imperial profusion. Besides these treasures of painting, the Hermitage now contains a collection of coins and medals, recently augmented by the acquisition of the famous cabinet formed by the late M. Reichel, which for the rarity and beauty of its pieces and the completeness of its historical series, is perhaps without a superior in Europe. An account of the curiosities preserved in the Hermitage would be imperfect without at least a passing mention of the portrait-gallery of the Russian sovereigns, as well as of a very singular collection of objects belonging to or connected with Peter the Great, exemplifying his skill in works of mechanical dexterity.

Many of the educational establishments of St Petersburg excite the surprise of the stranger, from the enormous scale on which they are maintained, as well as—to the honour of the government be it said—for the liberality with which they are administered. The Foundling Hospital, now rather a school for poor children than a receptacle for infants abandoned by their parents, is one of the largest establishments in Europe. The convent of Smolnoi, devoted

Petersburg.

to the education of young ladies of the noble and middle classes of society, is maintained in a great measure at the expense of the state. The special military schools, or cadet-corps, are also of extraordinary extent, some being devoted to particular branches of the service, as the artillery, the engineer department, roads and communications, mining (for everything in Russia is organized more or less on a military footing) the naval service, &c. &c. Of institutions of a purely civil nature and of the higher order, we may specify the university (now, 1858, numbering about 800 students), the law college, the Alexander Lyceum (the two latter devoted to the education of boys of the higher class, and together containing 400 pupils), 5 gymnasia (intended principally as preparatory to the university course, and numbering about 1250 scholars). In all these, as well as in the more special military schools, the pupils, and even the professors on ceremonial occasions, wear a military uniform, with the sword and cocked hat; though in the civil establishments, drilling and the use of arms do not form an indispensable part of the education.

The hospitals of St Petersburg are numerous and tolerably well administered; some of them are supported by the crown, and others founded by private charity, and devoted to particular classes of suffering humanity. The Academy of Medicine gives regular instruction to 450 students, who, after receiving a medical education at the expense of the state, are in some cases obliged to serve for a certain period in the interior and with the troops.

Among the more prominent scientific and literary institutions are the Academy of the Fine Arts, the Academy of Sciences, and in particular the Imperial Public Library, which contains upwards of 450,000 volumes of printed books, and more than 20,000 MSS., many of them of great rarity, particularly an immense number of autographs of illustrious persons, and works relating to oriental literature. This library has recently undergone great reforms in its administration, and is, like almost all collections, museums, &c., in Russia, opened to the public with great liberality.

The manufactures of St Petersburg are numerous and extensive. Some of them are carried on by the government, but the majority are in the hands of private individuals. Among the former are manufactories of gunpowder, tapestry, plate-glass and porcelain, and a cannon foundry. Of the other manufactures the principal are silk, cotton, and woollen goods, sailcloth, leather, glass, jewellery, paper, tobacco, mathematical and surgical instruments, &c.

The following table gives the movement of shipping at the port of St Petersburg during the last five years, together with the declared value of exports and imports, and the amount of the customs-duties collected during that time:—

Year.	Ships.	Tonnage	Imports.	Exports.	Customs from		
					Imports.	Exports.	Bridges.
			L.	L.	L.	L.	L.
1853	1,921	357,548	11,173,739	8,327,471	1,908,915	124.222	37,377
1854	17	3,490	3,827,080	1,498,543	1,023,573	6,736	20,287
1855	...	...	2,485,525	451,205	523,564		10,187
1856	3,374	519,710	10,766,949	8,586,775	1,384.254	13,288	26,602
1857	2,723	456,464	13,899,404	9,660,839	1,901,526	133,539	37,828

The principal countries trading with St Petersburg, with the numbers of vessels belonging to each, in 1857 were—England, 902 (tonnage 209,352); Holland, 549; Denmark, 212; Sweden, 150; Prussia, 141; Hanover, 139; Russia, 130; France, 128; Lubeck, 92; Norway, 90; Oldenburg, 62; America, 43; Naples, 35; Mecklenburg, 28; Bremen, 11; Hamburg, 7; Belgium, 2; Portugal, 2. Of the total number of vessels, 478 were steamers; and of these, 171 were English. The principal articles of import in 1857 were—gold and silver, L.488,773; sugar. 65 979.307 lb ; coffee, 6,716,676 lb.; tobacco, 2,163,494 lb.; wine in cask, 13,240,597 lb.; ditto in bottles, 978,794; olive oil, 13,256,739 lb.; dye-stuffs, 42,848,450 lb.; salt, 20,872,357 lb.; coal, 23,351 tons; raw cotton, 65,413,914 lb.; cotton yarn, 10,481,324 lb.; silk, raw and spun, 144,222 lb.; wool, spun, 2,394,454 lb.; cotton goods, 947,417 lb.; flaxen goods, 249,123 lb ; silk goods, 161,844 lb.; woollen goods, 525,147 lb. The chief articles of export during the same year were—gold and silver, L.167,414; hemp, 56,869,697 lb.; potash, 21,857,816 lb.; tallow, 97,228,918 lb ; raw hides, 6,034,558 lb., Russian leather, 894,010 lb., iron, 13,618,922 lb ; copper, 5,576,106 lb ; bristles, 2,503 289 lb.; cordage, 15,311,470 lb.; linen, 42,350 pieces; grain, 8,817,864 bushels.

Petersburg.

The population of the city, according to the census of 1856, was 490,808. The proportion of males to females is as two to one, arising from the great number of soldiers (principally the guard, which alone amounts to about 60,000 men) permanently stationed in and about St Petersburg, and the large population of peasants and workmen who come from the interior for a time, and return to their families after a longer or a shorter absence. The peasants, workmen, servants, and soldiers together constitute about three-fifths of the whole population; the nobles and *employés* about 44,000, the foreigners 16,000, the merchants 12,500, and the clergy 2500 The nobility form therefore about one-tenth of the total population; and it may be calculated that to every noble there are rather more than three servants. (T. B. S.)

PETERSBURG, *St*, a government of European Russia, lying between N. Lat. 58. and 60. 30.; and between E. Long. 27. 30. and 33. 30., bounded on the N. by the gulf and archduchy of Finland and by Lake Ladoga, E. by the government of Novgorod, S. by that of Pskov, and W. by Lake Peipus and the government of Esthonia. Length from N.E. to S.W., 265 miles; breadth, about 90 miles: area, 20,749 square miles. The surface is almost entirely level, and a great part of it is occupied with lakes and morasses. From a branch of the Valdai Hills, which occupies the S. of the government, the country slopes gradually downwards towards the N.W., and in this direction most of the rivers flow. The chief of these are the Nevà, flowing from Lake Ladoga to the Gulf of Finland; the Luga, which crosses the country from S.E. to N.W.; the Pliussa, flowing northwards, and falling into the Gulf of Finland near the mouth of the Luga; and the Volchov, by which the waters of Lake Ilmen in Novgorod are conveyed to Lake Ladoga. Besides the large lakes of Ladoga, Peipus, and Pskov, which lie on the frontiers of the government, there are many others of a smaller size in the interior. The soil is sandy, and the climate cold, moist, and unfavourable to agriculture. The forests of the government are of great extent, but carelessly managed. St Petersburg contained in 1849, 1,466,931 acres of arable land, 473,969 of meadows, 7,405,114 of wood, and 3,781,156 of waste land. In the same year the government produced 9,465,522 bushels of corn, and 1,463,278 of potatoes; and it possessed 118,849 horses, 183,783 horned cattle, 51,649 sheep, 20,666 swine, and 1075 goats. Rye, barley, oats, and wheat are the principal crops raised, but the produce of corn falls short of the demands of the people. Flax and hemp are also cultivated; and there are many kitchen gardens for the supply of the capital. Poultry of various kinds are kept, and fish are by no means scarce. The chief wealth of the country, however, depends on its timber, which forms an important article of export. Granite, limestone, marl, clay, and other minerals, are obtained in the government. Manufacturing industry is in a flourishing condition in St Petersburg; but this, as well as the commerce of the country, is for the most part confined to the capital. The government contained in 1849, 463 manufactories, employing 23,963 hands. Of the manufactories, the most important were 50 of tobacco, 47 of machines and hardware, 34 of silk, 23 of sugar, 27 of cotton cloth, 13 of woollen fabrics, 19 of glass and crystal, 15 of chemical substances, and 20 of leather. For the purposes of education the country belongs to the circle of St Petersburg, and contained in 1854, besides gymnasia and other superior institutions, 39 village schools, with 1220 scholars. The prevailing religion is that of the Greek Church; but there are 130,205 Protestants, 27,239 Roman Catholics, and a few Armenians, Mohammedans, and Jews among the population. In respect of race, the bulk of the people are

Russians, though there are also in the country many Germans, Finns, and others. For administrative purposes it is divided into 8 circles, and except the capital, it has no town of any importance. Pop. (1851) 566,409.

PETERSBURG, a town and port of the United States of North America, state of Virginia, on the right bank of the Appomattox, 10 miles above its confluence with the James river, and 22 S. of Richmond. It is handsomely built, principally of brick, and is a place of much commercial importance, being, in respect to size, the third town in the state. Among the public edifices are a court-house; a jail; eight churches, belonging to Presbyterians, Methodists, Episcopalians, Baptists, and Roman Catholics; and three banks. The manufacturing establishments are several cotton and one woollen factory, two rope-walks, an iron furnace, six forges, and several mills. A great amount of water-power for these works is furnished by the falls of the river just above the town. A canal has been made round the falls, by means of which small boats are enabled to ascend for about 100 miles higher. Vessels of 100 tons burden come up to the town, and those of a larger size discharge their cargoes at City Point, the point of confluence of the Appomattox and the James, whence there is a railway to Petersburg. The aggregate tonnage of the vessels registered at the port, June 30, 1852, was 484; of those enrolled and licensed, 2110. In that year there entered 16 vessels, tonnage 10,147; and there cleared 10, tonnage 5102. The principal exports are flour and tobacco, in large quantities. A great fire took place here in 1815, when nearly 400 houses were destroyed. Pop. (1850) 14,010, (1853) about 15,000.

PETERSFIELD, a parliamentary borough and market-town of England, county of Hants, stands near the Loddon, 18 miles E. by S. of Winchester, and 15 N.N.E. of Portsmouth. Though small, it is clean and neat, and the main street crosses nearly at right angles the London and Portsmouth road. The parish church is a large and ancient brick edifice, with fine Norman arches, and a low square tower. Petersfield has a town-hall, and a handsome statue of William III. on horseback. Churcher's College, an endowed charity school, founded in 1722, affords board, clothing, and education to twelve boys. There is also a library, a reading-room, and a savings-bank. A county court is held here. Besides weekly markets, there are two annual fairs for cattle and sheep. Petersfield never had any extensive trade, and what little it possessed was chiefly derived from its position on the London and Portsmouth road; but of even this advantage it has been deprived, by the construction of the railway between these places. The borough now returns only one member to Parliament; but previous to the passing of the Reform Act it sent two. Pop. (1851) 5550.

PETERSWALDAU, a town of Prussia, province of Silesia, government of Breslau, and 32 miles S.W. of that town. It consists of four parts—Royal, Middle, Lower, and Upper Peterswaldau. Of these the second is the largest, and contains a fine castle, one Roman Catholic, and two Protestant churches. It is a considerable manufacturing town, having tile-works, saw and other mills. Pop. of town, 6480, among whom are many Moravians.

PETERWARDEIN, or PETERVAR, a frontier town of Austria, capital of the Servian Military Frontier, stands on a promontory on the right bank of the Danube, which is here crossed by a bridge of boats, leading to Neusatz on the opposite side, 45 miles N.W. of Belgrade. It is one of the strongest places in the empire both by nature and art, as it occupies a high escarped rock, washed on three sides by the river, and has two fortresses, the one on the top of the rock, and the other, which incloses the town proper, on a gentle slope to the north. It presents a formidable appearance both from the river and the land, on account of the walls, pierced with port-holes, and the tiers of turf-covered bastions by which it is defended. The town, which consists of one main street, with two others parallel to it, contains an arsenal with many Turkish trophies, the parish church of St George, which has several interesting tombs, and other buildings. The lower fortress has large moats, which can be filled with water from the Danube. Peterwardein is said to derive its name from Peter the Hermit, who marshalled here the army of the First Crusade. The garrison amounts to about 3000 men, though it is capable of being augmented to 10,000. Pop. (exclusive of garrison), about 5000.

PETHERTON, NORTH, a town of England, in the county of Somerset, 7 miles N.E. of Taunton. It has one long street, and a large market-place. The parish church is a fine building, with a lofty tower. There is also a chapel of ease, and an endowed school for 20 boys. The people are for the most part employed in farming and retail trade. Though the market formerly held here is now discontinued, there are still two annual fairs. Pop. (1851) 3845.

PETHERTON, *South*, a market-town and parish of England, in the county of Somerset, 14 miles S.S.E. of Taunton. The church is large and elegant, in the form of a cross, and there are several Dissenting chapels. Sail-cloth and kid gloves are made here in small quantities. Pop. (1851) 2606.

PETHORA GURH, a military cantonment of British India, district of Kumaon, N.W. Provinces, about 10 miles from the right bank of the Kali, and 1200 N.W. of Calcutta. N. Lat. 29. 35., E. Lon. 80. 16. Attached to the cantonment is a bazaar and a large stone hospital, roofed with slates; and the whole place is commanded by Fort Loudoun, a hundred yards to the west.

PÉTION DE VILLENEUVE, JEROME, a leader of the French Revolution, was born at Chartres about 1753, and practised for some time at the bar. His first appearance on the stage of politics was in the character of deputy from the commons of his native town to the Estates-General in 1789. He then showed himself to be well fitted to walk circumspectly among the besetting perils of those troublous times. His political creed was liberal and settled, his disposition phlegmatic, his appearance imposing, and his elocution ready. Accordingly, in all the high and critical offices to which he was called during the Revolution, his character was notable for its cool consistency. As president of the National Assembly and of the Criminal Tribunal, he acted in such a straightforward manner that he acquired the surname of "the Virtuous." When he was sent to conduct the royal family home from their arrested flight, this want of respect of persons was carried even to an extreme. He "ate his luncheon, comfortably filled his wine-glass in the royal Berline, flung out his chicken-bones past the nose of royalty itself; and on the king's saying, 'France cannot be a republic,' answered, 'No, it is not ripe yet.'" Nor did his coolness forsake him during 1791 and 1792, when, in the capacity of mayor of Paris, it was his duty to guard the safety of the city. Raised aloft on the shoulders of two grenadiers, he quieted and dispersed the insurrectionary populace on the famous 20th of June. Mingling also with the bloodthirsty mob, he tried, with "the austere language of the law," to check the reckless massacres of September. At length, however, the dangers which Pétion had with stoical countenance outfaced so long, became too pressing for him. The proscription of his party by the Jacobins on the 31st May 1793, drove him and ten of his fellow Girondins to escape for their lives. As the eleven skulked through the country towards Bourdeaux, their enemies beset them at every turn of the road. At last the ever-thickening perils compelled them to separate, and hide their heads wherever they could. On a July morning of 1794, the dead body

of Pétion, along with that of Buzot, was found in a corn-field near Bourdeaux half-eaten by wolves. (See Carlyle's *French Revolution;* and *Biographie Universelle.*)

PETIS DE LA CROIX, FRANÇOIS, a great oriental scholar, was the son of François Petis, the French king's interpreter for the Oriental languages, and was born in Paris in 1653. His education was conducted with the view of fitting him for succeeding his father. He was first instructed in mathematics, astronomy, geography, design, and the eastern languages. Then the famous minister Colbert despatched him, when only sixteen, to complete his education in the East. He sojourned for three years and a half at Aleppo, familiarizing himself with the language and literature of the Arabs. The next two years were spent at Ispahan in the study of the Persian dialects, politics, arts, and sciences. He wound up this long and thorough course of training by applying himself for four years at Constantinople to the language and diplomacy of the Turks. Soon after his return to France in 1680, Petis entered upon a new career as secretary-interpreter to the marine. In this capacity his aid was employed in all the negotiations which France at that time transacted with the Eastern courts. He was engaged in forming treaties with Algiers in 1684, with Tunis and Tripoli in 1685, and with Morocco in 1687. The closing, like the opening part of Petis' career, was devoted to linguistic pursuits. He began to officiate as Arabic professor to the Collège Royal in 1692, and as Oriental interpreter to the king in 1695. At the same time his pen was actively employed in connection with his favourite studies. He published *Histoire de la Sultane de Perse et des Vizirs,* a translation from Sheikh Zadeh, in 12mo, 1707; and *Les Mille et Un Jours,* a translation from the Persian, in 5 vols. 12mo, Paris, 1710–12. Another translation, entitled *Histoire de Timur Bec,* in 4 vols. 12mo, appeared in 1722, nine years after his death. He also left behind him in manuscript several works on history, geography, and the Oriental languages, a list of which is given in Goujet's *Mémoire sur le Collège Royal.* (See *Biographie Universelle.*)

PETIT, JEAN-LOUIS, an eminent French surgeon, was born in Paris in March 1674. His love for his favourite science was early in action. When a mere child he began of his own accord to attend the lectures of Littre, the anatomical professor; not long afterwards he was surprised one day in a granary in the act of dissecting a rabbit; and at the age of twelve he had made such progress in his class, that he was entrusted with the care of the anatomical theatre. This precocious boyhood was the prelude to a manhood of great professional eminence. After practising for eight years with marked ability in the army, he returned to Paris in 1700, and took a high position as a promoter of surgical science. His *Traité sur les Maladies des Os,* published in 1705, originated a new branch of pathology. His appointment to the office of lecturer in the School of Surgery in 1724, and to the directorship of the Royal Academy of Surgery in 1731, inaugurated and established a new system of chirurgical instruction. His numerous pupils, also, carried his principles to the most remote countries. He died in 1750, the most famous surgeon in Europe. An extensive work on surgery, which Petit left unfinished, was completed and published by Dr Lesné, under the title of *Traité sur les Maladies Chirurgicales,* Paris, 1774. His other productions are contained in the Memoirs of the Academy of Surgery, and in those of the Academy of Sciences.

PETIT, *Pierre,* a French mathematician, was born at Montluçon in 1594, and removed from his native place to Paris in 1633. His apitude for the exact sciences soon opened up for him a career of distinction. The French government employed him to inspect the seaports of France and Italy, and appointed him provincial commissary of artillery and intendant-general of fortifications. Several scientific works in the meanwhile proceeded from his pen, and increased his reputation as a man of learning. He was also honoured to take part in the celebrated discussions touching the "Dioptrics" of Descartes, and to assist Pascal in making experiments on the phenomena of the common pump. The death of Petit took place at Lagny, on the Marne, in 1677. The following is a list of the most important works of Petit: *L'Usage du Compas de Proportion,* 8vo, Paris, 1634; *Observations touchant le Vide,* 4to, Paris, 1647; *Dissertation sur la Nature des Comètes,* 4to, Paris, 1665; and *Dissertation sur la Nature du Chaud et du Froid,* 12mo, Paris, 1671.

PETIT-CANAL, a town of the island of Guadaloupe, on a bay of the same name on the W. coast, about 9 miles N.E. of St Louis. Sugar is exported in great quantities; and in the surrounding country large herds of cattle are fed. A large proportion of the inhabitants are slaves. Pop. 7600.

PETITIO PRINCIPII. See FALLACY.

PETITOT, JEAN, a great improver of the art of painting in enamel, was the son of a sculptor and architect, and was born at Geneva in 1607. A series of incidents gradually led him to his famous improvement. Becoming an apprentice to a jeweller named Bordier, he was employed in painting enamels for jewels. His success soon became so great, that his master set him to draw miniature portraits on the same substance. Several colours were the only things wanting to enable the two to carry on their new profession. They found some of these colours on going and making application to the chemists of Italy. Then repairing to London, they obtained the rest from Sir Theodore Mayern, first physician to Charles I. Having thus perfected the art of painting portraits in enamel, Petitot entered upon a successful career as an artist. Many of Vandyck's pictures were given to him to be copied; that illustrious painter himself became his friend and adviser; the royal family sat to him; and the king attached him to his person, and gave him apartments in Whitehall. Even after the outbreak of the civil war had blighted his prospects in England, his prosperity still continued. He was retained for some time in the suite of the exiled Prince of Wales. He was then taken into the service of the French King, Louis XIV., and introduced into a new scene of professional success. A pension was bestowed upon him, and a lodging in the Louvre was allotted to him. He was employed in copying some of the celebrated pictures of Mignard and Lebrun, and in painting the portraits of King Louis XIV., and the Queens Anne of Austria and Maria Theresa. This sunshine of court favour lasted until he had amassed an immense fortune, and nearly reached the age of fourscore. The path of Petitot then began to be beset by troubles. Being a Protestant, he was alarmed at the revocation of the edict of Nantes, and became eager to return to his native country. On attempting to escape without the consent of the king, he was thrown into prison, and the eloquent Bossuet was employed to convert him to Popery. It was only after his health was undermined by imprisonment, and the ineffectual attempts to make him a proselyte, that his release was obtained. He had not been long in Switzerland when a stroke of apoplexy cut him off in 1691, in the act of painting a portrait of his wife. Fifty-six of the portraits of Petitot are preserved in the museum of the Louvre. His masterpiece, however, is the full-length portrait of Rachel de Rouvigny, Countess of Southampton, in the collection of the Duke of Devonshire.

PETIVER, JAMES, an eminent English botanist, born about the middle of the seventeenth century, but in what year is not known. His profession was that of an apothecary, which he exercised in Aldersgate Street, London, during the whole of his life. His business was extensive,

Petra.

and he afterwards became apothecary to the Charter-House. Excepting Sir Hans Sloane and Courten, he was the only person after the Tradescants who made any important collections in natural history, previously to those of the present day. He employed the captains and surgeons of different ships to bring him home specimens; and by means of printed directions he enabled them to select proper objects. In this manner his collection soon became so valuable, that, some time previously to his decease, he was offered L.4000 for it by Sir Hans Sloane, by whom it was purchased some time after Petiver's death. Both at home and abroad his fame was extended by his valuable museum. He was chosen a fellow of the Royal Society; and having become acquainted with Ray, he assisted him in arranging the second volume of his *History of Plants*. He died on the 20th of April 1718; and his funeral was honoured by the attendance of Sir Hans Sloane, and other eminent men, as pall-bearers. He published several works on different subjects of natural history, particularly *Musci Petiveriani Centuriæ decem*, 1692-1703, 8vo; *Gazophylacii Naturæ et Artis, Decades decem*, 1702, folio, with a hundred plates; *A Catalogue of Mr Ray's English Herbal*, illustrated with figures, 1713, and continued in 1715, folio; many small publications, which may be found enumerated in Dr Pultney's book; many papers in the *Philosophical Transactions*, and a valuable article in the third volume of Ray's work, entitled "Plantæ Rariores Chinenses, Madras-patanæ et Africanæ, a Jacobo Petivero ad opus consummandum collatæ." Many of his small tracts having become scarce, his *Opera Omnia* were collected and published, exclusively of his papers in the Transactions, 1764, in two vols. folio.

PETRA, the capital of Arabia Petræa, was situated between the Dead Sea and the Ælanitic Gulf. In the times of the Old Testament history it was called Selah, a word which, like Petra, its Greek name, means "a rock." It is recorded that Amaziah, king of Judah, "slew of Edom in the valley of Salt ten thousand, and took Selah by war, and called the name of it Joktheel unto this day." (2 Kings xiv. 7.) This name seems, however, to have passed away with the Hebrew rule over Edom, for no further trace of it is to be found; and it is still called Selah by Isaiah (xvi. 1). We next meet with it as the Petra of the classical writers. Strabo, writing of the Nabathæans in the time of Augustus, thus describes their capital:—"The metropolis of the Nabathæans is Petra, so called; for it lies in a place in other respects plain and level, but shut in by rocks round about, but within having copious fountains for the supply of water and the irrigation of gardens. Beyond the inclosure the region is mostly a desert, especially towards Judæa." (*Geog.* xvi.) Pliny more definitely describes Petra as situated in a valley less than two miles (Roman) in amplitude, surrounded by inaccessible mountains, with a stream flowing through it. (*Hist. Nat.* vi.) About the same period it is often named by Josephus as the capital of Arabia Petræa, with which kingdom it passed under the immediate sway of the Romans in the time of Trajan. In the fourth century it is several times mentioned by Eusebius and Jerome; and in the Greek ecclesiastical Notitiæ of the fifth and sixth centuries it appears as the metropolitan see of the third Palestine. From that date not the slightest notice of the city is to be found in any quarter until modern times. It was Burckhardt who first ventured to assume that the wonderful remains in Wady Musa were the ruins of the ancient capital of Arabia Petræa. His view was amply developed in his *Travels in Syria*, p. 431, published in 1822, and was supported and incontestably established by his editor, Col. Leake. (Leake's Preface to Burckhardt's *Travels in Syria*, pp. vii.–ix.) The ruined city lies in a narrow valley, surrounded by lofty, and, for the most part, perfectly precipitous mountains. The ancient and more interesting entrance is on the eastern side, through the deep narrow gorge of Wady Syke. A river, or rather mountain torrent, flows through this gorge and passes out into the valley nearly opposite to the point of entrance on the western side. The chief public buildings occupied the banks of the river and the high ground further south, as their ruins sufficiently show. One sumptuous edifice remains standing on the south bank, near the western side of the valley, and seems to have been a palace, rather than a temple. It is called Pharaoh's house, and is thirty-four paces square. A little east of this, and in a range with some of the most beautiful excavations in the mountain on the east side of the valley, are the remains of what appears to have been a triumphal arch. A few roods south are extensive ruins, which probably belonged to a temple, and which contain fragments of columns five feet in diameter. Still further south are other piles of ruins —columns and hewn stones—parts no doubt of important public buildings which occupied what may be called the central parts of Petra. A large surface on the north side of the river is covered with substructions, which probably belonged to private habitations. An extensive region still farther north retains no vestiges of the buildings which once covered it.

Petra.

The attention of travellers has however been chiefly engaged by the excavations which have more successfully resisted the ravages of time. These excavations, whether formed for temples, tombs, or the dwellings of living men, surprise the visitor by their incredible number and extent. They not only occupy the front of the entire mountain by which the valley is encompassed, but of the numerous ravines and recesses which radiate on all sides from this enclosed area. They exist, too, in great numbers along all the approaches to the place, which in the days of its prosperity were perhaps the suburbs of the overpeopled valley. At the same time they are often seen rising one above another in the face of the cliff to the height of from two hundred to three or four hundred feet above the level of the valley. By far the largest number of these excavations were manifestly designed as places for the interment of the dead; and thus exhibit a variety in form and size, of interior arrangement and external decorations, adapted to the different fortunes of their occupants, and conformable to the prevailing tastes of the times in which they were made. Some consist of a single chamber, 10, 15, or 20 feet square by 10 or 12 in height, containing recesses in the wall large enough to receive one or a few deposits. Others are enriched externally with various ornaments, representing columns of different orders, graceful pediments, broad, rich entablatures, and sometimes statuary, and transforming the base of the mountain into a vast, splendid pile of architecture. The magical effect of some of these monuments is greatly heightened by the rich and various colours of the rock out of which, or more properly in which, they are formed. The mountains that encompass the vale of Petra are of sandstone, of which red is the predominant hue. Many of them are adorned with such a profusion of the most lovely and brilliant colours as it is scarcely possible to describe. Red, purple, yellow, azure or sky blue, black, and white, are seen in the same mass distinctly in successive layers, or blended so as to form every shade and hue of which they are capable—as brilliant and soft as they ever appear in flowers, or in the plumage of birds, or in the sky when illuminated by the most glorious sunset. In fact, it is more easy to imagine than describe the effect of tall, graceful columns, exhibiting these exquisite colours in their succession of regular horizontal strata. They are displayed to still greater advantage in the walls and ceilings of some of the excavations where there is a slight dip in the strata.

Detailed descriptions of the principal monuments have been furnished by Laborde, *Voyage dans l'Arabie-Petrée*), Robinson (*Biblical Researches*), and Olin (*Travels in the*

East, from which the above description has been chiefly taken). Interesting notices of Petra may also be found in the respective Travels, Journeys, &c., of Burckhardt, Macmichael, Irby and Mangles, Stephens, Lord Lindsay, and Schubert.

PETRARCA, Francesco, one of the greatest poets and most celebrated men of whom Italy can boast, was born at Arezzo on the 20th of July 1304. His baptismal name was *Francesco di Petracco* (a form of Pietro), but the poet afterwards changed it into the more euphonious name by which he is always known. His father, the friend of Dante, and, like him, of the Ghibelin party, had been banished from Florence, where he filled a respectable situation confided to him by the republic; and having taken refuge in Pisa, he committed the education of his son, then in his seventh year, to an old grammarian of that city named Convennole da Prato. Two years afterwards, when the death of the Emperor Henry VII. had destroyed the hopes of the Ghibelins, the father of Petrarca removed his family to Avignon, whither Clement V. had transferred the pontifical court, and his son resumed his studies at Carpentras, under his former master. It was then that Francesco visited for the first time the fountain of Vaucluse; and the rural beauties of this celebrated spot left an indelible impression upon his mind. He passed four years at the university of Montpellier, whither he had been sent to study law, but not relishing legal literature, he devoted his days and nights to Cicero and to Virgil. But whilst engaged in these seducing pursuits, he was disturbed by the arrival of his father, who, greatly incensed at what he conceived to be a gross misapplication of time, consigned to the flames the little library of his son, and was with difficulty induced to restore to him Cicero and Virgil, after they had been half consumed. Being now sent to the university of Bologna, to receive the instructions of Giovanni d'Andrea, the most learned canonist of that age, Petrarca soon formed a connection there with Cino da Pistoia, a Florentine like himself, whom Bartolo cites as his master in the science of law, and who deserved to become that of Petrarca and Boccaccio in poetry. At the age of twenty-two he lost his father, and being ruined by faithless tutors, he returned to Avignon, where he took up his residence, appeared with distinction in the most brilliant society, and found himself at liberty to apply to his favourite pursuits. Mathematics, history, antiquities, and philosophy occupied, each in its turn, a mind thirsting for knowledge. The first poetical attempts of Petrarca, like those of Dante, were made in the Latin language; but, happily, his muse soon ventured to confide her inspirations to the vulgar tongue, the only one, besides, which the women understood.

About this time he renewed his acquaintance with one of his school companions, Jacopo Colonna, the youngest son of Stefano Colonna, the head of the illustrious family of that name. In the society of the Colonnas, the poet became known to the most illustrious strangers who visited the pontifical city; whilst the noble frankness of his manner, his mild yet sprightly physiognomy, the graces of his mind, and his unaffected anxiety to please, secured him a remarkable ascendancy in this select circle. When Jacopo Colonna was called to the bishopric of Lombes, his friend accompanied him to his diocese, and in their way they stopped at Toulouse. The seven Maintainers of the Gay Science were then beginning to diffuse a taste for the vulgar poetry, and to bring into notice those little effusions of song unknown to the ancients, and some of which have still remained peculiar to the literature of the troubadours. A submissive and unfortunate lover, Petrarca, like them, sought to console himself by singing at once the charms and the cruelty of his beloved. On the 6th of April 1327 he had seen, in a church of Avignon, the daughter of Audibert de Noves; and the passion he conceived for this lady occupied the remainder of his life, over which it diffused an air of poetry and romance. Laura was united to Ugo de Sade, a young patrician, and a native of Avignon; and faithful to her duties as a wife and a mother, she forbade Petrarca to indulge the slightest hope. Incessantly haunted with this beautiful vision, the poet visited in succession the south of France, Paris, and the Low Countries. The forest of the Ardennes re-echoed in turn his verses and his lamentations; he traversed Burgundy, the Lyonnais, Dauphiné, and, after an exile of eight months, returned to bury himself in the delightful solitude of Vaucluse.

Pope John XXII. was then meditating a new crusade, and, to further his object, he led the Romans to hope that he would re-establish the chair of St Peter in Italy. This double project excited the imagination of Petrarca, and inspired his beautiful ode to his friend the Bishop of Lombes, *O aspettata in ciel*, &c. The following year (1335) we find him expressing, in elegant Latin verses addressed to Benedict XII., his earnest desire to see the Holy See re-established in the eternal city; and to this patriotic aspiration the Pope replied by appointing him canon of Lombes, with the hopes of a prebend. The same year was marked by an event unique in the life of Petrarca. A recent and close connection attached him to the interests of Azzo da Corregio, one of the principal Lords of Italy, who was then prosecuted before the papal courts at the instance of the family of the Rossi. In the hope of serving his friend, the poet resolved to plead his cause at the bar; and this he did with so eminent success that it proved to both a day of triumph. Since he had first beheld Laura, he sought occupation everywhere without being able to fix himself anywhere. After visiting Rome, he returned to Avignon, and finally shut himself up in his retreat at Vaucluse, where he made the acquaintance of Filippo di Cabassole, Bishop of Cavaillon, whom the poet calls a little bishop and a great man.

Meanwhile he commenced writing in Latin the History of Rome from the foundation of the city to the reign of Titus. But in collecting materials for this work he was much struck with the grandeur of the events which had marked the termination of the second Punic war; and suddenly conceived the design of giving to his age a regular epic, of which Scipio should be the hero. Before the end of the year, the poet was in a condition to submit to his friends the greater part of his work, which they received with the most flattering encomiums. But a more grateful distinction awaited him. His Sonnets and his *Canzoni* had filled France and Italy with the name of Laura and that of her lover; in fact, these pieces were universally read and admired. Of the impression produced by his poetical genius he had soon the most convincing evidence. On the 23d of August 1340, he received at Vaucluse two letters, one from the Roman senate, which invited him to accept the poetical laurel, and be crowned in the capitol, and the other from the chancellor of the university of Paris, which offered him the same triumph. Petrarca had long coveted the poetic laurel, and even made known his wishes to Robert of Anjou, King of Naples, whose influence had stimulated the admiration, and hastened the decision, of the Roman senators. This prince cultivated letters with enthusiasm, and protected them in a manner worthy of a king. Wishing to appear indebted to him for the crown which had been offered to him, Petrarca embarked for Naples, carrying with him his epic poem, which he had entitled *Africa*. The king and the poet had repeated conferences upon the subjects of poetry and history; and at his audience of leave, Robert, divesting himself of his robe, put it on Petrarca, at the same time requesting him to wear it on the day when he was to receive the laurel crown.

The poet then repaired to Rome, and on Easter-day (the 8th of April 1341) ascended the Capitol, in the midst

Petrarca.

of the principal citizens; received the crown from the hands of the senator Orso, Conte di Anguillara; recited a sonnet upon the heroes of ancient Rome; was conducted to the church of St Peter, where he deposited on the altar the laurel which encircled his brow; and then set out for Avignon by land, as if to enjoy more leisurely his renown. He carried with him the title of almoner to the king of Naples, and letters-patent giving him, as well by the authority of King Robert as by that of the senate and people of Rome, full and free permission to read, vindicate, and explain the ancient books, to make new ones, compose poems, and on every occasion to wear the crown of laurel, ivy, or myrtle, at his pleasure.

Azzo da Corregio having just usurped the sovereignty of Parma, on the pretext of freeing it from thraldom, urgently pressed Petrarca to spend some time with him; and, captivated by the attentions paid to him, the poet soon accepted the situation of archdeacon of the church of Parma, caused a house to be built there, and then employed himself in completing his poem of *Africa*. Glory had now begun to console him for his labour and anxiety, when envy, awakened by unexampled success, attempted to disturb his repose; and at the same time the hand of death had stricken the bishop of Lombes, his best friend and warmest admirer. The accession of Clement VI. to the triple crown, in 1342, revived in the mind of Petrarca hopes which had already been twice disappointed. At the request of the Romans, he accompanied to Avignon the deputation they had sent for the purpose of soliciting the new pope to fulfil the promises made by John XXII., and, in this matter, he acted as the organ of the deputation. The pontiff received him with marked distinction, appointed him prior of Migliorino, in the diocese of Parma, and treated him with the greatest familiarity, but made no answer to the petition of the deputation, beseeching him to remove to Italy. At the same time, however, his holiness, anxious to testify the confidence he reposed in Petrarca, intrusted him with a delicate mission, namely, that of obtaining from the regency of Naples a recognition of the rights of the Holy See, during the minority of the grand-daughter of King Robert. Meanwhile, the celebrated Cola di Rienzi, having made himself master of Rome, cited kings to appear before him, and loudly proclaimed that his fellow-citizens were about to resume, in the fourteenth century, their ancient dominion over the world. All the illusions of Petrarca immediately brightened into realities. An ardent defender of the tribune even in the midst of the pontifical court, he now congratulated the popular leader on his success, exhorted him to persevere, and, impatient to counsel him on the spot, set out immediately for Italy. The news of the massacre of the Colonnas reached him at Genoa, and struck him with consternation; but still he felt disposed to pardon Rienzi, provided Rome had become republican. The sway of the tribune, however, was short-lived, and with his fall disappeared that wild phantom of liberty which had deceived Petrarca.

Scarcely a year had elapsed when the poet had to bewail a loss still more painful. Laura was no more. The pestilence of 1348, which Boccaccio has described with such terrible truth, had carried her off on the 6th of April that year. The last half of the *Canzoniere* is an immortal monument of the long regret of Petrarca. But although his verses had not made us aware of the sincerity of his grief for his mistress, the touching note which he inscribed upon his copy of Virgil would still attest the profane homage which he paid to her memory.[1] Yielding to the repeated instances of Luigi Conrado, lord of Mantua, Petrarca now repaired to his princely residence, in the hope of finding consolation; and it was during his stay there that he addressed to the Emperor Charles IV. an eloquent letter, in which he exhorted him to restore peace to Italy. The publication of the jubilee in 1350 drew almost all Christian Europe to Rome. Petrarca, participating in this pious impulse, set out for Rome, and in passing through Florence, visited Boccaccio, one of those whom he had particularly noticed at the court of Naples, and who now became his friend. At Rome he found the jubilee commenced, and the ceremonies of the occasion seem to have made a deep impression on his mind. His habits became more grave, his manners more austere; and from this time his thoughts assumed a character of severity, the impress of which is visible in his later compositions. At the same time he everywhere received honours which had never before been bestowed on any private individual.

The friendship of the Carraras having induced Petrarca to visit Padua, he had scarcely arrived when Boccaccio came to announce to him, in the name of the senate of Florence, that he had been re-established in his rights as a citizen, as well as in the patrimony of his family, and also to offer him the directorship of the university recently founded in the first city of Tuscany. This honourable appointment, however, had no attraction for Petrarca. His books awaited him in his transalpine Parnassus, as he called Vaucluse; and his cisalpine Parnassus was his house at Parma. He accordingly declined accepting the proffered appointment, and hastened to bury himself in his favourite retreat. About the same time, Rienzi, having fallen into the hands of the emperor, was delivered up to the pope, and brought before a judicial commission, against the legality of which he vehemently protested. It is said that Petrarca wrote to the Roman people, warmly exhorting them to interpose in favour of his old friend; and, in fact, this exhortation is found in his works. But there is nothing to show that it was sent according to its address; on the contrary, almost every circumstance leads us to believe that his imagination alone had prompted him to write this letter, rather to console than to save Rienzi.

On his return to Vaucluse, he engaged in the composition of the "Epistle to Posterity," in which he gives an account of the principal events of his life, until his departure from Italy, about the middle of the year 1351.[2] Some months afterwards, Innocent VI. was called to the government of the church,—a man of an irreproachable life, but of little knowledge, and the only pontiff from whom Petrarca did not receive some mark of favour. The poet, after having twice, under Clement IV., refused the office of apostolical secretary, was now suspected of magic by his successor, and he took no pains to dispel the prejudices of the new pontiff. His regret for Italy was only increased; and he repassed the Alps, uncertain where to fix his abode, although prepared to adopt as his country any place where he might live in tranquillity and independence. He had long wished to visit Milan, and, on this occasion, he proceeded no farther. Charmed with the reception he met with from a man of power, who knew well how to exhibit himself to the poet in an amiable light, and admitted to the counsels of Giovanni Visconti, archbishop and lord of Milan, Petrarca accepted a mission having for its object to bring about a reconciliation between the republic of Genoa, which had just given itself up to Visconti, and that of

[1] The authenticity of this note is still disputed by those who wish to overturn the whole history of Laura. Mr Whyte, a learned Englishman, who discovered at Florence an inedited life of Petrarca, written soon after his death, by Luigi Peruzzi, who had known him, also rejects the evidence of this note. But it is written in a tone which ought to silence incredulity, because feigned emotions never bear the stamp of nature and reality. The Virgil of Petrarca has long been in the royal collection at Paris.

[2] Ginguené (*Histoire Littéraire d'Italie*, tom. ii., p. 582) shows, contrary to the opinion of Badelli, that the "Epistle to Posterity" was written in 1352, and not in 1372.

Petrarca.

Venice, elated by recent and apparently decisive successes. Three years before, Petrarca had endeavoured to prevent a war which presaged long and bloody divisions in Italy. Connected with the Doge Andrea Dandolo, one of the greatest men of his age, in politics, in war, and in letters, the poet appealed to the patriotism of his friend, and the latter replied by praising the eloquence of Petrarca, but without deferring to his counsels. Hence this new attempt proved not more fortunate than the previous one; but events soon showed on which side lay the want of foresight. Venice was reduced to the necessity of purchasing peace; Dandolo died of grief, and Visconti survived him little more than a month. Nevertheless, after a silence of three years, the emperor replied to the letter in which Petrarca had called upon him to restore peace to his country, an appeal which he had several times renewed. But the avarice of Charles IV. furnished a more powerful motive to appear in Lombardy than the patriotic addresses of Petrarca. By his orders the poet proceeded to meet him at Mantua, full of confidence in his wisdom, and hoping that, as the friend of the Holy See, he would for ever banish from Italy the names of Guelf and Ghibelin, which had caused the effusion of so much blood, and fomented such fierce animosities. But in this monarch he discovered only a weak and avaricious prince, who mistook treachery for talent, and exhibited the strange spectacle of an emperor of Germany in the pay of the Venetians. The poet presented him with some rare and valuable medals of Augustus, of Trajan, and the Antonines. "These," said he, "are the great men whose place you occupy, and who ought to be your models." During eight days which he spent in familiar intercourse with the emperor, Petrarca discovered the mean, narrow, and grovelling character of his mind, and refused to enter Rome in his train, or to be a witness of his coronation. He then attached himself more than ever to the three nephews of Giovanni Visconti, whom the emperor had loudly menaced, with the view of enhancing the price to be afterwards exacted for confirming them in the usurpations of their uncle. At this period, the public hatred had accused them of fratricide. Petrarca, afflicted with a rumour which he could not believe, repaired to Pavia, where he was employed by Galeazzo Visconti to dissuade Charles IV. from undertaking a new expedition beyond the Alps. This embassy proved more successful than the former, apparently because the proceedings of the malcontents in Germany had produced a change in the versatile policy of the emperor. On his return to Milan, the ambassador received from him the diploma of Count Palatine, in a gold box of considerable value. Petrarca accepted this new honour, but returned the box to the chancellor of the empire.

Fatigued with the agitation of courts, the poet now fixed upon a new retreat on the banks of the river Adda, in a pretty country-house, which he called Linterno, in honour of his hero Scipio. Literary projects and researches, religious exercises, and frequent visits to the charter-house of Milan, now occupied his leisure. All the great lords of Italy had disputed with pontiffs and kings the honour of his presence and conversation. But a goldsmith of Bergamo, named Capra, solicited and obtained a sort of preference. At the approach of Petrarca all Bergamo went out to meet him, whilst Capra received him with a magnificence almost royal, and proved by his enthusiasm, not less than by the number and quality of his books, that he was worthy of his guest. In 1360 a new diplomatic mission led Petrarca to France, whither he went to compliment King John on the recovery of his liberty; and this prince, who had formerly made vain attempts to prevent his return to Italy, now renewed his efforts to retain him. But the envoy of Galeazzo returned to Milan, without suffering himself to be moved either by the presents of the monarch or by the entreaties of the dauphin; and those of the emperor, backed by the transmission of a gold cup of curious workmanship, found him equally inflexible. But never had a residence in Italy presented fewer attractions. The foreign companies who infested that land of discord forced him to seek an asylum at Padua, whence he was soon afterwards expelled by the pestilence. He proceeded to Venice, accompanied with his books, which he always carried along with him, and, on his arrival, he presented his library to that hospitable republic, by a writing dated in 1362, on condition that so rare a collection should neither be divided nor sold. By a decree of the senate, a palace was assigned for the reception of Petrarca and his books; and it is, doubtless, this circumstance which has made him be regarded as the original founder of the celebrated library of St Mark.[1] The Abate de Sade is therefore mistaken in supposing that all these manuscripts had perished. Tomasini, who made a search for them in the year 1635, discovered them in a small dark chamber, situated near the four bronze horses; and there they remained until the year 1739, when permission was at length given to the public to consult them.[2]
